Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

We wish to dedicate this seventh edition of *Pedretti's Occupational Therapy: Practice Skills for Physical Dysfunction* to Lorraine Williams Pedretti, whose thoughtfulness, love of her profession, and dedication to the education of her students provided the impetus to embark on the daunting task of writing and editing an original textbook (and ensuing editions) for evaluation and treatment of adults with physical disabilities. As academic colleagues of Professor Pedretti, we were inspired by her example and challenged to accept the responsibility to continue in her footsteps to contribute to the advancement of the profession. It is our hope that our efforts have honored her example and lived up to her faith in us.

We would also like to dedicate this edition to occupational therapy students (past, present, and future) who are the future of our wonderful profession: may you find the happiness and fulfillment that we have as proud occupational therapists.

This page intentionally left blank

Foreword

It is an honor and a privilege to write the foreword to the seventh edition of *Pedretti's Occupational Therapy: Practice Skills for Physical Dysfunction*. I was the book's original author, and the primary editor of the first five editions. The book had its inception in 1981. It has been widely used by occupational therapy students in the United States and abroad for the past 30 years. Over this time, it has enjoyed a reputation for its practical and comprehensible writing, and for covering the essential theoretical and practical information needed for clinical practice. As editions progressed, the text evolved to keep pace with changes in the rapidly growing body of knowledge and expanding areas of clinical practice in occupational therapy. It is very gratifying for me to know that this book continues to be an important resource for students, occupational therapy educators, and clinicians in the profession.

I was very pleased that my professional colleagues at San Jose State University, Dr. Heidi McHugh Pendleton and Dr. Winifred Schultz-Krohn, will continue as its editors. Dr. Pendleton, who was my student many years ago, joined the faculty of San Jose State University in 1987 after many years of clinical practice, working with clients with physical dysfunction. It was gratifying to witness her professional and academic development, to observe her numerous professional achievements, and to see her earn the doctorate in the field. She is currently serving as Chairperson of the Department of Occupational Therapy at San Jose State University, and received the Lifetime Achievement Award from the Occupational Therapy Association of California in 2011.

Dr. Winifred Schultz-Krohn came to San Jose State University in 1996 with excellent credentials and qualifications. She has many years of clinical practice in pediatrics, is a board-certified pediatric occupational therapist, and has previous academic experience. She has extensive education and expertise in neurological dysfunction. She continued her outstanding academic achievements and earned her doctorate while on the faculty at San Jose State University. Professor Schultz-Krohn was recently awarded the prestigious Jefferson Award for more than 12 years of pro bono occupational therapy services to the San Jose Family Homeless Shelter. Her tireless volunteer work ranged from developing and supervising a summer OT fieldwork program to providing practicum and research opportunities to hundreds of occupational therapy students.

These editors are professional and academic leaders in the field. They have published numerous articles and book chapters and have received many professional awards and recognitions. They have clinical and academic expertise and a wealth of professional knowledge that makes them

eminently qualified for the editorial roles they have undertaken. They have done an excellent job in authoring chapters and coordinating the preparation of the sixth and seventh editions.

These editors have assembled a roster of excellent contributors: leaders and experts in the occupational therapy profession who are well qualified to write on their respective subjects. As the profession grew and changed, the content and format of the textbook evolved to reflect the changes. Therefore, more contributors were invited to participate in the preparation of each edition. There are almost 60 contributors in the seventh edition, nine of whom are new contributors.

The content of the seventh edition reflects the substantive changes that have occurred in occupational therapy philosophy and practice. The content has been restructured and is based on the new Occupational Therapy Practice Framework-2, with more emphasis on evidence-based practice and client-centered practice. The content reflects new research and theories, new techniques, and current trends in the profession. This fresh new approach includes case studies, clinical reasoning skills, ethical questions and concerns, factors of cultural diversity, and practice notes that are threaded throughout the book. There are two new chapters: **Chapter 13, Sleep and Rest**; and **Chapter 48, Polytrauma and Occupational Therapy**. The enhanced content will teach the student essential clinical reasoning skills and provoke thinking about potential ethical and cultural considerations in treatment. There is comprehensive coverage of physical dysfunction. Especially exciting is the accompanying Evolve website for students and instructors. This development brings this textbook into the electronic information age and has great potential for independent study by students and as a resource for occupational therapy educators.

Writing and editing a textbook is no small task. It takes a great deal of time, patience, and persistence. It involves dealing with numerous people—editors, contributors, vendors, models, photographers, and artists. I was so fortunate that my worthy colleagues agreed to adopt this textbook and keep the production going after my retirement. I am very grateful that they have produced this excellent work, and so pleased that it will continue to be associated with the occupational therapy program of excellence at San Jose State University.

Lorraine Williams Pedretti, M.S., OTR/Ret
Professor Emeritus
San Jose State University
October 2011

This page intentionally left blank

Preface

It was a great honor to be asked to assume the editorship of the seventh edition of *Pedretti's Occupational Therapy: Practice Skills for Physical Dysfunction*. To continue to follow in the footsteps of the inimitable Lorraine Pedretti is at once an awesome responsibility and a rewarding journey. The opportunity to work with authors, each a leading expert in his or her field, continues to be an unparalleled experience of the exceptional ability of stellar occupational therapists to organize their time and unselfishly devote their scholarship to the education of future generations of the profession.

Since the publication of the sixth edition, there have been changes within the profession and within the clinical practice of occupational therapy for clients with physical dysfunction. Many of those changes served to shape the approach we took to the new edition and are reflected within the context of each of the chapters. Our mission and intention was to embrace these changes and continue to honor the primacy of occupation that has been the foundation of this textbook for the past several editions.

The seventh and latest edition is framed and guided by the Occupational Therapy Practice Framework: Domain and Process—2nd (OTPF-2), designed to describe the focus and dynamic process of the profession. Key to the OTPF-2 is its view of the overarching goal of occupational therapy; that is, engagement in occupation to support participation in life. This conceptualization of the importance of occupation is emphasized throughout the text. Two chapters are devoted to explicating this new model, and the language and the concepts that comprise the model are incorporated into each of the remaining chapters. The concepts of process and practice, evaluation and intervention, performance skills and patterns, contexts and activity demands, client factors, and intervention applications are all thoroughly illustrated throughout.

To honor the centrality of the client to occupational therapy practice, the chapters begin with case studies, which are then threaded throughout, guiding the reader through the information and relating the content to the specific case descriptions. Thus, the reader is able to experience the clinical reasoning and decision-making skills of the expert clinicians who authored the chapters. Authors of individual chapters were asked to follow the initial presentation of their case studies by crafting several probative or “critical thinking” questions that would pique the readers’ curiosity, further motivating their attention to and questioning of the chapter content and consequently facilitating the learning process. Direct answers to these critical thinking questions

are provided either within or at the end of each of the chapters.

This textbook, written for an intended audience of master’s degree occupational therapy students and as a reference for practicing occupational therapists, has always been acknowledged for its practical application and focus on practice. Theory and evidence-based content are presented in each chapter and then applied using case descriptions as a foundation for practice. Occupational therapy’s role in health and wellness, as well as prevention, is addressed throughout the text. Similarly, occupational therapy’s commitment to the importance of considering cultural and ethnic diversity is reflected in every chapter.

New features provided by the publisher’s editorial staff are the OT Practice Notes and the Ethical Considerations boxes that are highlighted throughout many of the chapters. The information contained in these boxes (pulled from the chapter content) conveys ideas that are relevant to students’ future practice areas and thoughts about some of the possible ethical dilemmas and decisions with which they might be confronted. New support materials include the Evolve website, which includes both a link to student-related materials as well as an instructor link with access to the Instructor’s Resource Manual (also available in printed and CD-ROM version) and a test bank.

During the process of editing this book, including the stages of envisioning and designing the content and format, selecting the authors, and reading and giving input to their work, we were guided by our commitment to honoring the occupational welfare of our clients, particularly adults with physical disabilities, through excellent preparation of their future occupational therapists. To that end we sought pre-eminent authors, those who not only had recognition for expertise in their topic area, but who also embraced the primary importance of occupation to their practice and scholarship. Our goal was to engender excitement in the reader for occupational therapy in the area of physical dysfunction, while providing cutting-edge information and promoting models of best practice. Our extensive and rewarding clinical and academic careers in the profession of occupational therapy and our experiences with hard-working and inspiring clients and students served as the inspiration for our best efforts, which we trust are evident in this book.

**Heidi McHugh Pendleton
Winifred Schultz-Krohn**

Acknowledgments

We would like to thank the authors, past and present, for their exceptional contributions and willingness to continue the tradition of excellence that has come to be associated with the Pedretti book. The impressive list of authors for the seventh edition continues the Pedretti reputation for including nationally and internationally known experts in their topic areas and disciplines. We are fortunate to feature contributions from new authors and included among them are administrators, educators, researchers, and master clinicians.

We would also like to acknowledge the superb contribution of the dedicated editors and staff at Elsevier. We are especially grateful to Kathy Falk, Senior Editor, and Jolynn Gower, Developmental Editor, who patiently and painstakingly mentored us through the long and arduous editing process. They are simply outstanding! Our thanks go to Rich Barber, project manager, who, with exceptional attention to detail, made sure that the final product reflected the efforts of all involved.

To those publishers and vendors who permitted us to use material from their publications, we extend our sincere gratitude. Photographers and artists, and the clients and models who posed for photographs, are gratefully acknowledged. Michelle Tipton Burton and Monica Bascio were particularly generous in finding just the right photographs to capture the importance of occupation to participation in life—we thank you!

Finally, we would like to extend heartfelt appreciation to our colleagues, friends, and families, without whose help and support this accomplishment could not have been achieved. Special expressions of *thank you* go to the faculty and staff at San Jose State University, who could be counted upon for their support and good wishes during this process.

Heidi McHugh Pendleton extends her gratitude to her husband, Forrest Pendleton (for immeasurable love and support without which this endeavor could never have succeeded) and to her sisters, Deirdre McHugh and Kathleen McHugh (for a lifetime of support). Her love and appreciation go to all of her nieces, nephews, and stepson, including Dar, Jim, Nicky, Elizabeth, Jimmy D, Megan, Kelsey, Jamie, Jessica, and Katie—their love and enthusiasm make everything possible.

Winifred Schultz-Krohn extends a huge thank you to her always supportive, ever-patient husband, Kermit Krohn. His tireless love made the project possible. She is also very grateful for the support and encouragement received from her brother, Tom Schultz; his wife, Barb Fraser; and niece, Sarah; her sister, Donna Friedrich; husband, Don; nephews, Brian and Andrew; Andrew's wife, Kirsten; and grand nephew, Zachary; sister, Nancy Yamasaki; and husband, Bryan. She is also grateful for the support and encouragement she received from her parents, Don and Eleanor Schultz, when taking on this project. Unfortunately they did not live to see the completion of this project.

The co-editors would like to thank each other—great friends at the beginning of the process—we were able to be there for each other, make our own unique contributions, and ultimately sustain our friendship throughout the process, emerging even better friends in the joy of our accomplishment.

Client factors

Evaluation

■ **Learning Objectives** After studying this chapter, the student or practitioner will be able to do the following:

1. Briefly describe the history of the evolution of the Occupational Therapy Practice Framework, both the original OTPF and OTPF-2.
2. Describe the need for the OTPF-2 in the practice of occupational therapy (OT) for persons with physical disabilities.
3. Describe the fit between the OTPF-2 and the International Classification of Function and Disability (ICF) and how they inform and enhance the occupational therapist's understanding of physical disability.
4. Describe the elements of the OTPF-2, including domain and process and the relationship of each to the other.
5. List and describe the components that make up the occupational therapy domain, and give examples of each.
6. List and describe the components that make up the occupational therapy process, and give examples of each.
7. Briefly describe the occupational therapy intervention levels, and give an example of each as it might be used in a physical disability practice setting.

Threaded Case Study | Kent and Karen, Part 1

Kent is a highly skilled and very competent occupational therapist with more than 25 years of clinical experience working in a large rehabilitation center with adult clients who have physical disabilities. He is currently the supervising occupational therapist on the spinal cord injury (SCI) unit. Through his reading of occupational therapy (OT) publications,^{2,11,12,15,19} attendance at conferences and workshops, and interactions with his OT staff and interning OT students, he has become increasingly knowledgeable regarding the Occupational Therapy Practice Framework (OTPF) and now, the OTPF-2. Initially he was annoyed that, among the many challenges to his professional time and efforts, he would now have to learn, yet again, a new “language” in order to provide competent intervention and that even before he has mastered the new model there is now an updated second edition. He secretly expressed feelings such as “why fix something that isn't broken?” However, he reluctantly acknowledged the necessity for the change, is impressed by what he has learned so far, and is convinced that he can no longer postpone delving in and really learning and implementing the OTPF-2 into his clinical practice.

Throughout his practice, Kent has found it helpful to relate new or novel occupational therapy information he is learning to the relevant circumstances that either he or one of his clients is experiencing, and consequently he considers the impact the new information might have on either his own life or that of his client.

While learning the OTPF-2 (also referred to as the Framework II), he decided to keep in mind one of his most recently admitted clients, Karen, a single, 25-year-old woman living alone in her own apartment, working as an administrative assistant for a busy law office, who incurred a cervical SCI and now has C6 functional quadriplegia that necessitates using a wheelchair for mobility. By keeping Karen in mind, Kent expects not only to learn the Framework II but to also reinforce his new knowledge by putting it to immediate use in his practice.

Critical Thinking Questions

As you read through the chapter, keep in mind the challenges that learning the OTPF-2 and integrating it into practice will pose for Kent. Think of strategies that you might recommend or use yourself to learn and integrate the information into your practice. Also, consider the objectives for the chapter outlined previously as well as the following questions:

1. Why was there a need for the OTPF and OTPF-2, and how do they fill that need?
2. How might the specific information being presented about the OTPF-2 apply to Kent or Karen?
3. Are there tools that Kent and other OT practitioners can use that will facilitate learning the OTPF-2 and integrating it into practice?

The Occupational Therapy Practice Framework, Second Edition: Overview

Many changes have occurred in the practice of occupational therapy (OT) for persons with physical disabilities since the publication of the previous edition of *Occupational Therapy: Practice Skills for Physical Dysfunction* in 2006. Occupational therapy practice settings are increasingly moving away from traditional healthcare environments, such as the

hospital and rehabilitation center, and have made significant strides moving more toward the home and community milieu. The provision of occupational therapy service has become more client centered and the concept of occupation is increasingly and proudly named as both the preferred intervention and the desired outcome of the services. Clinicians, researchers, and scholars have sought to implement evidence-based practice by learning more about the benefits of occupation to not only remediate problems after the

onset of physical disability but also to anticipate and prevent physical disability and promote wellness. Not surprisingly, economic concerns have severely shortened the amount of time allotted for OT services, thus necessitating more deliberate and resourceful decisions about how these services can most effectively be delivered.

In response to these changes, and many other practice advances, came a change, or evolution, in the language with which occupational therapists describe what they do and how they do it. This change resulted in a document called the “Occupational Therapy Practice Framework” (OTPF) and the now updated second edition (OTPF-2), a tool developed by the profession to more clearly articulate and enhance the understanding of what OT practitioners do (occupational therapy domain) and how they do it (occupational therapy process). The intended beneficiaries of the OTPF and OTPF-2 were envisioned as including not only OT practitioners (an internal audience) but also the recipients of OT services (called clients), other healthcare professionals, and those providing reimbursement for OT services (comprising an external audience).

The OTPF was developed, resulting in the “Occupational Therapy Practice Framework: Domain and Process,”¹ which was published in the *American Journal of Occupational Therapy (AJOT)* in 2002. This initial iteration of the Framework was put to practice and its relevance and efficacy assessed resulting in the now updated OTPF-2, which was developed and thoroughly articulated in the “Occupational Therapy Practice Framework: Domain and Process,” Second Edition,² which was published in the *AJOT* in 2008. This is an important document every OT practitioner will want to have and reference frequently. It can be downloaded from the American Occupational Therapy Association (AOTA) website by selecting AJOT Online and the November/December 2008 issue. Another helpful tool for learning the OTPF is the original introductory article in the November/December 2002 issue of the *AJOT* by Youngstrom titled “The Occupational Therapy Practice Framework: The Evolution of Our Professional Language.”²²

It is not the intention of this chapter to supplant the comprehensive OTPF-2 document but, rather, to describe and increase the reader’s understanding of the OTPF-2 and its relationship to the practice of occupational therapy with adults who have physical disabilities. To achieve this, the chapter begins with a discussion of the history of the OTPF-2 followed by sections describing the need for the OTPF-2 and the fit between the OTPF-2 and the World Health Organization’s (WHO) International Classification of Function and Disability (ICF). Next, a detailed description of the Framework II is presented with emphasis on fully explicating the domain of occupational therapy through examples from the case study and introducing the occupational therapy process, which will be discussed more thoroughly in Chapter 3 on application of the OTPF to physical dysfunction. The types of occupational therapy intervention proposed by the Framework II are examined

and illustrated by examples typically employed in physical disabilities practice settings. The chapter concludes with suggestions and strategies for learning the OTPF-2 and an overview of how the Framework II is integrated as a unifying thread throughout the remaining chapters in the book.

History of the Evolution of the OTPF

In 1999, the Commission on Practice (COP) of the AOTA was charged with reviewing the “Uniform Terminology for Occupational Therapy,” Third Edition (UT-III).³ Under the leadership of its chair, Mary Jane Youngstrom, the COP sought feedback from numerous and varied OT practitioners, scholars, and leaders in the profession regarding the continued suitability of the UT-III to determine whether to update the document or to rescind it. Previous editions of the UT in 1979 and 1989 had been similarly reviewed and updated to reflect the changes and evolving progress of the profession. The reviewers found that the UT-III, though considered a valuable tool for occupational therapists, was lacking in clarity for both consumers and professionals regarding what occupational therapists do and how they do it. Furthermore, they found that the UT-III did not adequately describe or emphasize OT’s focus on occupation, the foundation of the profession.

Given the feedback from the review, the COP determined the need for a new document that would preserve the intent of the UT-III (outlining and naming the constructs of the profession) while providing increased clarity about what occupational therapists and occupational therapy assistants do and how they do it. Additionally, it was determined that this new document would refocus attention to the primacy of occupation as the cornerstone of the profession and desired intervention outcome as well as show the process occupational therapists use to help their clients achieve their occupational goals.

Need for the OTPF

The original OTPF and the revised OTPF 2 make it clear that the profession’s central focus and actions are grounded in the concept of occupation. Although some of what occupational therapists do could be construed by clients and other healthcare professionals as similar to or even duplication of the treatment efforts of other disciplines, formally delineating occupation as the overarching goal of all that OT does, and clearly documenting such goals, establishes the profession’s unique contribution to client intervention.

This is not to say that prior to the OTPF, OT practitioners did not recognize or focus on occupation or occupational goals with their clients—most did; but in the physical disabilities practice setting, with the reductionistic, bottom-up approach and pervasive influence of the medical model, occupation was seldom mentioned or linked to what was being done in OT. A premium seemed to be placed on “medical speak,” and it was difficult, if not impossible, to document occupational performance or occupational goals

in the types of documentation that were characteristic of physical disabilities practice settings. Kent, the therapist from the case study, still occasionally experiences the medical team members' heightened interest as he reports muscle grades and sensory status, contrasted with their quizzical, glazed-over looks when he describes his clients' difficulties with resuming homemaking, leisure, or other home and community skills. The OTPF-2 provides a vehicle to communicate with others besides occupational therapists that engagement in occupation should be the primary outcome of all intervention.

The OTPF-2 provides a language and structure that communicates occupation more meaningfully. It empowers occupational therapists to restructure evaluation, progress, and other documentation forms to reflect the primacy of occupation to what OT does, and shows the interaction of all the aspects that contribute to supporting or constraining the client's participation. Thus, by clearly showing and articulating the comprehensive nature of OT's domain of practice to clients, healthcare professionals, and other interested parties, occupational therapists enlist support and demand for their services and, most important, ensure that clients will receive the unique and important services that only OT provides. Of equal importance is that the Framework II positions the client as a collaborator with the occupational therapist at every step of the process, thus empowering the individual as a change agent and reframing the image of the client as a passive recipient of services.

Fit between the OTPF-2 and the ICF

There appears to be an excellent fit between the OTPF-2 and the ICF. At about the same time the UT-III was being studied for continued suitability regarding contemporary language and practice, the WHO was also revising its language and classification model. The resulting WHO International Classification of Functioning, Disability and Health (ICF) contributes to the understanding of the complexity of having a physical disability.²¹ The ICF “moved away from being a ‘consequences of disease’ classification to become a ‘components of health’ classification” (p. 4),²¹ progressing from impairment, disability, and handicap to body functions and structures, activities, and participation. In the ICF, the term *body structures* refers to the anatomic parts of the body and *body functions* refers to a person's physiologic and psychological functions. Also considered in this model is the impact of environmental and personal factors as they relate to functioning. The ICF adopted a universal model that considers health along a continuum where there is a potential for everyone to have a disability.

The ICF also provides support and reinforcement for OT to specifically address activity and activity limitations encountered by persons with disabilities.²¹ This document describes, as well, the importance of participation in life situations, or domains, including (1) learning and applying knowledge, (2) general tasks and task demands, (3) communication, (4) movement, (5) self-care, (6) domestic life

areas, (7) interpersonal interactions, (8) major life areas associated with work, school, and family life, and (9) community, social, and civic life. All of these domains are historically familiar areas of concern and intervention to the profession of OT. Although a physical disability may compromise a person's ability to reach up to brush his or her hair, the ICF redirects the service provider to also consider activity limitations that may result in restricted participation in desired life situations such as sports or parenting. A problem with a person's bodily structure, such as paralysis or a missing limb, is recognized as a potentially limiting factor, but that is not the focus of intervention.

Occupational therapy practitioners believe that intervention provided for people with physical disabilities should extend beyond a focus on recovery of physical skills and address the person's engagement, or active participation, in occupations. This viewpoint is the cornerstone of the Framework II. Such active participation in occupation is interdependent on the client's psychological and social well-being, which must be simultaneously addressed through the occupational therapy intervention. This orientation is congruent with the emphasis of the WHO ICF.

The language of the UT-III was, in many instances, different from that used and understood by the external audience of other healthcare professionals. Similarly, the terminology of the previous WHO classification frequently differed from that used by the audience with whom the organization was trying to communicate (e.g., healthcare professionals and other service providers). The goals of the new WHO classifications, the ICF, are to increase communication and understanding about the experience of having a disability and unify services. In a similar manner, the original OTPF, and now the updated OTPF-2, was designed to increase the knowledge and understanding of the OT profession to others and, where appropriate, incorporate the language of the ICF, as will be seen in the following discussion of the OT domain and process. Detailed information on the ICF can be found in the document referenced in this chapter,²¹ or an overview of the document can be downloaded from www3.who.int/icf/cfm.

The OTPF-2: Description

The OTPF-2 is composed of two interrelated parts, the domain and the process. The domain comprises the focus and factors addressed by the profession, and the process describes how occupational therapy does what it does (evaluation, intervention, and outcomes)—in other words, putting the domain into practice. Central to both parts is the essential concept of occupation. The definition of occupation used by the developers of the original Framework is as follows:

Activities ... of everyday life, named, organized, and given value and meaning by individuals and a culture.
Occupation is everything people do to occupy themselves,

including looking after themselves, ... enjoying life, ... and contributing to the social and economic fabric of their communities. (p. 32)¹³

In the revised Framework II, rather than adopting one definition, occupation is defined in the document as the numerous iterations presented in the OT literature. The committee charged with the revision of the OTPF ultimately suggest that an array of several selected definitions of occupation offered by the scholars of the profession add to an understanding of this core concept. These selected definitions can be found on pages 628-629.²

Adopting the essence of these definitions, the developers of the OTPF-2 represent or characterize the profession's focus on occupation in a dynamic and action-oriented form, which they articulate as supporting health and participation in life through engagement in occupation. This phrase links both parts of the Framework II, providing the unifying theme or focus of the occupational therapy domain, as well as the overarching outcome of the occupational therapy process.

The Occupational Therapy Domain

The domain of occupational therapy encompasses the gamut of what occupational therapists do, along with the primary concern and focus of the profession's efforts. Everything that the OT does or is concerned about, as depicted in the domain of the OTPF-2, is directed at supporting the client's engagement in meaningful occupation that ultimately affects the health, well-being, and life satisfaction of that individual.

The six broad areas or categories of concern that constitute the occupational therapy domain include performance in areas of occupation, performance skills, performance patterns, context, activity demands, and client factors (Figure 1-1). The developers of the Framework point out that there is a complex interplay among all of these areas or aspects of the domain, that no single part is more critical than another, and that all aspects are viewed as influencing engagement in occupations. Furthermore, the success of the occupational therapy process (evaluation, intervention, and outcomes) is incumbent on the occupational therapist's expert knowledge of all aspects of the domain.

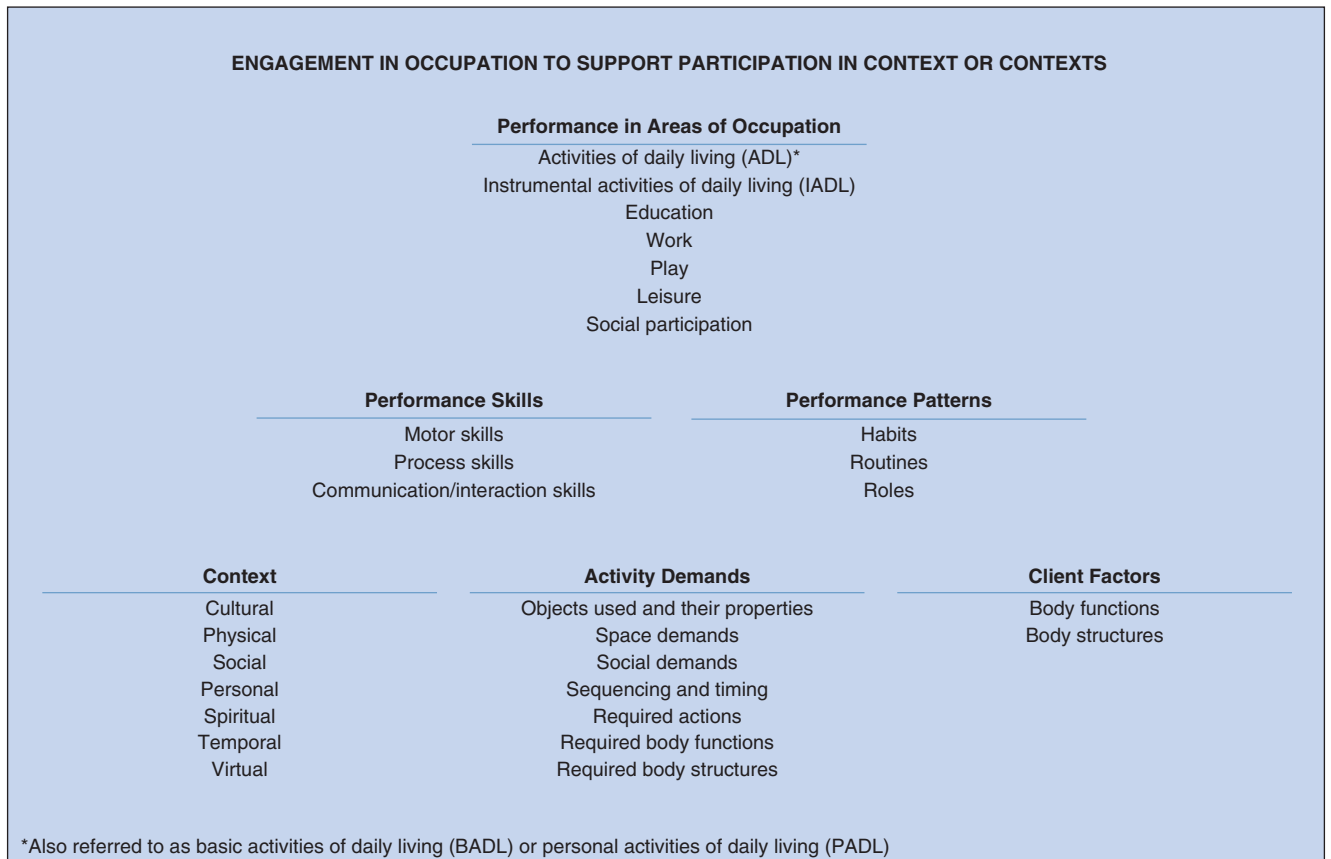

FIGURE 1-1 Occupational therapy domain.
 (From American Occupational Therapy Association: Occupational therapy practice framework: domain and process, *Am J Occup Ther* 62(6):625-688, 2008.)

Performance in Areas of Occupation

Occupational therapists frequently use the terms *occupation* and *activity* interchangeably. Within the Framework II, the term *occupation* encompasses the term *activity*. Occupations may be characterized as being meaningful and goal directed but not necessarily considered by the individual to be of central importance to her or his life. Similarly, occupations may also be viewed as (1) activities in which the client engages, (2) activities that have the added qualitative criteria of giving meaning to the person's life and contributing to one's identity, and (3) activities in which the individual looks forward to engaging. For example, Karen, Kent's client with quadriplegia, regards herself as an excellent and dedicated clothes and accessories shopper; holidays and celebrations always include her engagement in her treasured occupation of shopping. Kent, on the other hand, regards the activity of shopping for clothes as important only to keep himself clothed and maintain social acceptance. Kent avoids the activity whenever possible. Each engages in this activity to support participation in life but with a qualitatively different attitude and level of enthusiasm. Within the OTPF-2, both of these closely related terms are used, recognizing that individual clients will determine those that they regard as meaningful occupations and those that are simply necessary occupations or activities that support their participation in life; for Kent, shopping is a necessary occupation or activity, but for Karen, it is a favorite occupation.

Included in the areas of occupation category of the domain are eight comprehensive types of human activities or occupations. Each is outlined in the following discussion, with a listing of typical activities that are included in each and examples from the physical disability perspective as provided by Karen's circumstances.

Activities of daily living (ADLs) (also referred to as personal activities of daily living [PADLs] or basic activities of daily living [BADLs]) are activities that have to do with accomplishing one's own personal body care. The body care activities included in this category are bathing/showering, bowel and bladder management, dressing, eating, feeding, functional mobility, personal device care, personal hygiene and grooming, sexual activity, and toilet hygiene.

Instrumental activities of daily living (IADLs) are "activities to support daily life within the home and community that often require more complex interactions than self-care used in ADL" (p. 631).² The specific IADLs included in the domain are care of others (including selecting and supervising caregivers), care of pets, child rearing, communication management, community mobility, financial management, health management and maintenance, home establishment and management, meal preparation and cleanup, religious observance, safety and emergency maintenance, and shopping. Knowing that the IADL of shopping was certain to be a priority occupation for Karen, Kent made a note of the full description of shopping from the corresponding lists of IADLs in Table 1: Areas of Occupation of the OTPF-2

Threaded Case Study Kent and Karen, Part 2

As Kent perused the list of activities of daily living (ADLs), he noted that virtually every category, with the exception of eating (which involves the ability to keep and manipulate food in the mouth and the ability to swallow), would be of concern to his client Karen because of the nature and extent of her SCI disability. When Kent discussed this list with Karen, she viewed practically all as necessary activities but personally valued feeding, sexual activity, and personal hygiene and grooming as being extremely important to her satisfactory participation in life. Karen was a little surprised to learn that sexual activity was included; "So this is occupational therapy? Maybe I'll wait awhile before I talk about this topic, but it's good to know I'm expected to be interested though," she thought.

For the present, Karen turned her attention to and took particular interest in the activities included in the personal hygiene and grooming category and its detailed description (found in Table 1 in the OTPF-2 document): "Obtaining and using supplies, removing body hair (use of razors, tweezers, lotions, etc.), applying and removing cosmetics, washing, drying, combing, styling, brushing and trimming hair; caring for nails (hands and feet), caring for skin, ears, eyes, and nose, applying deodorant, cleaning mouth, brushing and flossing teeth; or removing, cleaning, and reinserting dental orthotics and prosthetics" (p. 631).² The numerous details reminded her of how important all of these grooming activities were to her and were suggestive of the scope of the daily activities she would like to address in OT. Of particular concern to Karen were the grooming activities of plucking her eyebrows and styling her hair; these were bodily care activities she regarded as very personal. In fact, she was reluctant to let anyone do these for her. Though under similar circumstances Kent might have gladly deferred these two ADLs, it was clear that Karen would prioritize them as personally meaningful occupational goals.

In studying the list of ADLs, Kent noted that each ADL item listed, just like personal hygiene and grooming, had a similarly helpful definition and detailed list of examples located in the tables throughout the OTPF-2 document. He remembered reading that these lists were there to give a few examples, were not to be considered exhaustive, and in fact, there was an expectation that the lists would be modified and expanded on as the OTPF-2 became more familiar and integrated into practice.

document. Shopping is described there as "Preparing shopping lists (grocery and other); selecting and purchasing items; selecting method of payment; and completing money transactions" (p. 631).² This is not as detailed as some descriptions, but it is a good start for looking at the related activities that would have to be addressed if Kent and Karen were to collaborate on Karen's resumption of engagement in shopping. Kent noted too that community mobility

included driving and using public transportation, another IADL that would be important to explore with Karen as she contemplates returning to paid work. In fact, the entire list of IADLs held numerous concerns to be addressed in OT.

Rest and sleep, formerly considered a subcategory in the area of occupation of ADLs, is now afforded recognition as a separate area of occupation in the OTPF-2 and “includes activities related to obtaining restorative rest and sleep that supports healthy active engagement in other areas of occupation” (p. 632).² The component activities constituting rest and sleep include rest, sleep, sleep preparation, and sleep participation (see Chapter 13 for an expanded discussion of this important area of occupation). For Karen, her sleep occupations will be significantly changed as the result of her diagnosis with the need for frequent repositioning during the night for skin precautions as well as setting up equipment to manage her bladder function while she sleeps, to name just a few concerns that OT will need to address.

Education is an area of occupation that includes “activities needed for learning and participating in the environment” (p. 632).² Specific education activity subcategories include formal education participation, informal personal educational needs or interests exploration (beyond formal education), and informal personal education participation. Table 1 of the OTPF similarly includes more details regarding what specific activities each of these subcategories could entail.

Work includes activities associated with both paid work and volunteer efforts. Specific categories of activities and concerns related to work include employment interests and pursuits, employment seeking and acquisition, job performance, retirement preparation and adjustment, volunteer exploration, and volunteer participation.

Activities associated with play are described as “any spontaneous or organized activity that provides enjoyment, entertainment, amusement, or diversion” (p. 252).¹⁶ Considered under this area of occupation are play exploration and play participation.

Leisure is defined as “nonobligatory activity that is intrinsically motivated and engaged in during discretionary time, that is, time not committed to obligatory occupations such as work, self-care or sleep” (p. 250).¹⁶ Leisure exploration and leisure participation are the major categories of activity in the leisure area of occupation. Karen shared with Kent her interests in spending leisure time listening to music, traveling, antiquing, swimming, playing bridge, and reading books. When looking at the description of leisure, it occurred to Kent that for Karen, shopping might also be characterized as a leisure activity as well as an IADL. It would probably depend on the circumstances or context in which it was engaged, he thought, another parameter of the OTPF-2 domain he would be learning.

Social participation is an area of occupation that encompasses the “organized patterns of behavior that are characteristic and expected of an individual or a given

position within a social system” (p. 633).² The area of social participation further encompasses engaging in activities that result in successful interaction at the community, family, and peer/friend levels. Just as in previously discussed areas of occupation, Table 1 of the OTPF-2 provides definitions and more detailed information regarding the breadth of activities that constitute OT’s involvement in work, play, leisure, and social participation. Like Kent, readers who are currently learning the OTPF-2 could benefit from studying these expanded lists to broaden their understanding of occupational therapy’s domain. As Kent studied these sections of Table 1, he found it helpful to make note of the content of each as illustrated by activities that were relevant to Karen in these areas of occupation. For example, Kent considered the range of job skills and work routines necessary for Karen to return to her paid position as an administrative assistant as well as similar concerns involved with resumption of her preferred play and leisure occupations including swimming, reading, and board games. Kent was also reminded of the importance of considering the activities that can support or constrain Karen’s continued social participation in her community as a Girl Scout leader, in her family as the oldest daughter, and with her treasured circle of friends.

Performance Skills and Performance Patterns

The reader is reminded throughout the OTPF-2 document that there is no correct or incorrect order in which to study or follow the areas of the domain—“all aspects of the domain transact to support engagement, participation, and health” (p. 628)—there is no hierarchy.² With this in mind, the next main areas of the domain to consider are performance skills and performance patterns. Both are related to the client’s capabilities in performance in the areas of occupation previously described and can be viewed as the actions and behaviors that are observed by the OT as the client engages in occupations.

The category of performance skills includes five components of concern: motor and praxis skills, sensory-perceptual skills, emotional regulation skills, cognitive skills, and communication and social skills. The client’s successful engagement in occupation or occupational performance is dependent on having or achieving adequate ability in performance skills. In the OTPF-2, performance skills are defined as the abilities clients demonstrate in the actions they perform. Problems in any of the five areas of performance skills are the focus for formulating short-term goals or objectives to reach the long-term goal of addressing participation in occupation.

Motor skills consist of actions or behaviors a client uses to move and physically interact with tasks, objects, contexts, and environments including planning, sequencing, and executing new and novel movements. Definitions of praxis skills provided in Table 4 include “skilled purposeful movements; ability to carry out sequential motor acts as part of an overall plan rather than individual acts; ability to carry

out learned motor activity, including following through on a verbal command, visual-spatial construction, ocular and oral-motor skills, imitation of a person or an object, and sequencing actions; and organization of temporal sequences of actions within the spatial context, which form meaningful occupations” (p. 640).² Examples of motor and praxis skills include coordinating body movements to complete a job task, anticipating or adjusting posture and body position in response to environmental circumstances such as obstacles, and manipulating keys or a lock to open a door.

Kent observed Karen as she played a game of bridge with friends one afternoon in the OT clinic. Observing performance skills, particularly motor skills and praxis skills, Kent noted that Karen looped one elbow around the upright of her wheelchair, leaned her trunk toward the table, reached her other arm toward the cardholder, and successfully grasped a card using tenodesis grasp after three unsuccessful attempts (which Kent perceived as indicating planning, sequencing, and executing new and novel movements).

Sensory-perceptual skills, a second category of performance skills, are the “actions or behaviors a client uses to locate, identify, and respond to sensations and to select, interpret, associate, organize, and remember sensory events based on discriminating experiences through a variety of sensations” (p. 640) that include all of the sensory systems.² Among the many examples of sensory perceptual skills offered in Table 4 are positioning the body in the exact location for a safe jump and visually determining the correct size of a container for leftover soup.

Emotional regulation skills, the third category of performance skills, involve those “actions and behaviors a client uses to identify, manage and express feelings while engaging in activities or interacting with others” (p. 640).² Such skills could include persisting in a task despite frustrations and displaying emotions that are appropriate for the situation.

Cognitive skills compose the fourth category of performance skills and are defined as the “actions or behaviors a client uses to plan and manage performance of an activity” (p. 640),² including selecting necessary supplies and multitasking, which involves doing more than one thing at a time for tasks such as work.

The fifth category of performance skills—communication and social skills—is described as the “actions or behaviors a person uses to communicate and interact with others in an interactive environment” (Fisher, 2006) (p. 641).² Among the examples offered are taking turns during an interchange with another person and acknowledging another person’s perspective during an interchange (Table 4).²

While Karen played cards, Kent was also able to observe a wide array of examples of Karen’s performance skills. Her sensory perceptual skills were evident as she set up her cardholder so that her cards were within her reach and not visible to her opponents (selecting proper equipment and

arranging the space), perused her cards, paused, rearranged them using her tenodesis hand splint (attending to the task, using both knowledge of bridge and selection of proper equipment), and then stated her bid (demonstrating the cognitive skills of discernment and problem solving).

While playing cards, Karen was observed to be furrowing her brow, squinting her eyes shut in a thoughtful cogitating manner, pursing her lips, and showing neither happiness nor despair on her face as she studied her cards in the cardholder (expressing affect consistent with the activity of card playing and thus demonstrating or displaying appropriate emotions as well as cognitive skill in determining her next strategy). As she reached for the cards, the holder moved out of her reach; she asked the friend next to her to push it back, cautioning her in a smiling and light manner, “Don’t dare look!” (demonstrating her ability to multitask—asking for assistance and simultaneously using socially acceptable teasing behavior [communication and social skills] that enlists an opponent’s cooperation in preserving the secrecy of her cards, thus conveying the image indicative of a savvy card player). Her observable performance skills support Karen’s continued inclusion with friends in a favorite leisure occupation.

Each of these particular motor and praxis skills, sensory-perceptual skills, emotional regulation skills, cognitive skills, and communication and social skills categories has detailed lists of representative skills annotated with definitions, descriptions, and examples outlined in Table 4: Performance Skills, in the OTPF-2 document.

Performance patterns are observable patterns of behavior that support or constrain the client’s engagement in occupation. Types or categories of patterns include habits, routines, roles, and rituals.

In the OTPF-2, habits are described for the individual or person as “automatic behavior that is integrated into more complex patterns that enable people to function on a day-to-day basis”—they can be “useful, dominating, or impoverished and either support or interfere with performance in areas of occupation” (p. 642).² Some examples of habits offered are automatically putting car keys in the same place and spontaneously looking both ways before crossing the street (Table 5A).² Routines reflect the “patterns of behavior that are observable, regular, repetitive, and that provide structure for daily life. Furthermore, routines can be satisfying, promoting, or damaging. Routines require momentary time commitment and are embedded in cultural and ecological contexts” (p. 643).² Routines reflect how the individual configures or sequences occupations throughout his or her daily life. Habits typically contribute (positively or negatively) to one’s occupational routines and both are established with repetition over time. The role category of performance patterns is regarded as being composed of “sets of behaviors expected by society, shaped by culture, and may be further conceptualized and defined by the client” (p. 643).² Rituals are described as “symbolic actions with spiritual, cultural, or social meaning,

contributing to the client's identity and reinforcing values and beliefs. Rituals have a strong affective component and represent a collection of events" (p. 643).² Definitions and examples of performance patterns for organizations and for populations are outlined in Tables 5B and 5C on page 644 of the OTPF-2 document. Performance patterns for the

individual or person and how these can support (or by inference hinder) occupational performance are further illustrated in Part 3 of the threaded case study, "Kent and Karen."

Context and Environment

The OTPF-2 states that a "client's engagement in occupation takes place within a social and physical environment situated within context. The physical environment refers to the natural and built nonhuman environment and the objects in them and the social environment encompasses the presence, relationships, and expectations of persons, groups, and organizations with whom the client has contact" (p. 642).² Contexts are regarded as the interrelated conditions, circumstances, or events that surround and influence the client and in which the client's daily life occupations take place. Contexts can either support or constrain health and participation in life through engagement in occupation. In the domain of OTPF-2, contexts are composed of six categories or types including cultural, physical, social, personal, temporal, and virtual. Several of the categories of context are regarded as external to the individual such as physical, social, and virtual contexts; some are viewed as internal to the client, such as personal context. Some contexts, such as culture, provide an external expectation of behavior that is often converted into an internal belief. Table 6 in the OTPF-2 document provides detailed definitions and examples of each of these categories. For example, the category of context labeled "physical" encompasses the "nonhuman aspects of contexts. It includes the accessibility to and performance within environments having natural terrain, plants, animals, buildings, furniture, objects, tools or devices" (p. 645).² Personal context describes "features of the individual that are not part of the health status" (p. 17).²¹ Personal context includes age, gender, socioeconomic status, and educational status.

Each of these contexts and environments, as they pertain to Karen's specific circumstances, will significantly affect her future engagement in occupation. Karen's physical context includes aspects that will support her engagement in occupation including an accessible work site and a reliable and accessible system of public transportation in her neighborhood as well as a well-appointed downtown area of stores, shops, and restaurants within wheelchair distance. Those aspects of her physical environment and context that may interfere with resumption of occupation include Karen's inaccessible second floor apartment and small inaccessible bathroom. Supportive aspects of Karen's personal context are her college education in business and the fact that she has unemployment insurance that will supplement her sick leave and continue her health coverage. From a social context perspective, Karen is supported by both her family and friends; additionally, her employer and coworkers are anxious to have her come back to the law firm. The mainstream American cultural context in which Karen was reared—which values and supports the concepts of hard

Threaded Case Study Kent and Karen, Part 3

Some might view Karen's engagement in the occupation of paid work as an example of the role of worker. Inherent in this role are accepted norms that customarily include regular attendance, timely adherence to schedules, and acceptance of responsibility for completing assignments. Karen's work role is consistent with the sets of behaviors that would be expected of an administrative assistant at a busy law firm including arriving at work on time, handling e-mail and other correspondence in a professional manner, managing the office budget and payroll according to accepted audit practices, and interacting with her supervisors, coworkers, and supervisees in a fair and respectful manner, to name just a few. In tribute to her stellar work performance a ritual that has evolved as a part of Karen's work role experience at the law office is the annual Christmas Holiday Shopping Day. Karen and her three administrative assistant colleagues are given the Friday before Christmas off with pay. A town car picks them up at their homes and transports them to the downtown shopping district where they are given a generous gift card, a spa morning, lunch at a downtown restaurant, an afternoon of shopping, and town car transportation home at the end of the day.

Karen's workday routine involves waking at 6:30 a.m., showering, grooming, and dressing, driving to work with a stop for breakfast on the way, and arriving to her workplace early, at 7:45 a.m., for an 8:00 a.m. expected work start. For Karen, a habit she regards as beneficial to her workday routine is her prompt use of her day planner to record appointments, phone numbers, and additions to her things-to-do list. Another habit she believes contributes to the success of her workday routine is selecting her clothing the night before to save time in the morning, thus ensuring a punctual arrival at work. A habit that negatively affects her daily work routine is hitting the snooze button on her alarm clock. Both Kent and Karen recognize that though Karen may resume her work occupation or worker role, her ability to carry out the expected behaviors and her customary habits and routines will be substantially altered and expanded as the result of her SCI. Successful integration of these new habits and routines will undoubtedly determine the continuation of Karen's participation in the highly anticipated and beloved Holiday Shopping Day ritual.

Karen's occupational performance, performance skills, and patterns will be significantly influenced by the next three main areas of the domain to be discussed, namely, contexts and environments, activity demands, and client factors.

work overcoming adversity (doing rather than being) and the importance of independence (individualism)—seemingly motivates Karen to resume engagement in previous levels of occupation for full participation in all contexts of her life.⁷

Given the difficulty that resuming Karen's shopping occupation may present, Kent suggested the possibility of using online shopping for some items. Although interested, Karen indicated that her preference was to shop "in the real world" instead of using the virtual context of computers and airways. Her ultimate decisions will no doubt be influenced by the changes she experiences in her temporal contexts as Karen experiences and adjusts to the increased amounts of time, and scheduling of and around the time of others, required to accomplish basic daily routines that, in turn, support her engagement in preferred occupations.

Activity Demands

Activity demands are focused on the activity and what is required to engage in the activity. Included in this section are several aspects that must be addressed for a client to perform that specific activity, including the following: objects and their properties, space demands, social demands, sequencing and timing, required actions, required body functions, and required body structures. Table 3 of the OTPF-2 document provides a comprehensive list of definitions and examples for a clearer understanding of each of these categories.² Consider Karen's interest in shopping in the "real world" instead of making clothing purchases online using a virtual context. The materials or tools needed would be a purse or credit card holder. The space demands would be the accessibility of the store or shopping mall and the dressing room for Karen to try on the clothes before making a purchase. The social demands include paying for the items before leaving the store. The sequence and timing process includes being able to make a selection, go to the register, potentially wait in line, place the clothing on the counter, pay for the item, and then leave the store. The required actions refers to the necessary performance skills to engage in this activity such as the coordination needed to try on clothing, the process skills needed to select one sweater or blouse from a large array of possible choices, and the communication skills needed to ask for assistance or directions if needed.

These performance skills are not viewed in isolation but are seen as Karen engages in the activity of clothes shopping. The required body functions and structures refer to the basic client factors needed to perform the activity of shopping. The act of shopping requires a level of consciousness because inherent in the activity of shopping is having the opportunity to make a choice between available items. Karen's ability to engage in the activity demand of making a choice of purchases is indicative of her adequate level of consciousness for shopping.

Client Factors

The OTPF-2 describes client factors in a manner similar to the ICF.^{2,21} There are three categories in this portion of the OTPF-2: values, beliefs, and spirituality; body functions; and body structures. These three client factor categories are regarded as residing within the client and may affect performance in areas of occupation.²

The client factor category of values, beliefs, and spirituality includes values (principles, standards, or qualities considered worthwhile or desirable by the client who holds them), beliefs (described as cognitive content held as true), and spirituality (representing one's "personal quest for understanding answers to ultimate questions about life, about meaning, and the sacred") (p. 28).¹⁴ For example, Karen's values, including her strong work ethic and her beliefs and spirituality provide her the reassurance that her spinal cord injury (SCI) was part of a higher power's plan for her and that she will be given the strength to cope and succeed.

The body structure category refers to the integrity of the actual body part such as the integrity of the eye for vision (see Chapter 24) or the integrity of a limb (see Chapter 43). When the integrity of the body structure is compromised, it can impact function or require alternative approaches to engagement in activities, such as enlarged print for persons with macular degeneration or the use of a prosthesis for a person who sustained a below-elbow amputation. It is unlikely that this category of the domain would have application to Karen, because the integrity of her body structures is not necessarily compromised by her diagnosis. Should she develop a pressure sore, a possible complication of SCI, where the integrity of the body structure (i.e., skin) is compromised, her ability to engage in occupation could become significantly limited requiring alternative approaches such as positioning devices and adaptive equipment to compensate for the need to stay off the pressure sore.

The body function category of client factors refers to the physiologic and psychological functions of the body and includes a variety of systems including, for example, the neuromusculoskeletal and movement-related functions. This category of body functions includes muscle function, which in turn includes muscle strength. A distinction is made between body functions and performance skills. Performance skills, as was described earlier, are observed as the client engages in an occupation or activity. The category of body function refers to the available ability of the client's body to function. A client may have the available neuromuscular function (client factor of body function; specifically, muscle strength) to hold a comb and bring the comb to the top of the head, and strength to pull the comb through the hair, but when you ask the client to comb his or her hair (an activity), you observe that the client has difficulties manipulating the comb in the hand (motor skill of manipulation) and smoothly using the comb to comb

hair (motor skill of flow). These motor skills are included as performance skills in the OTPF-2.

In Karen’s case, absence of functioning muscles in her hands necessitates the use of a functional hand splint or adaptive writing device to enable her to sign the credit card receipt, a required action in her shopping occupation. In order to use a wrist-driven flexor hinge (i.e., tenodesis) hand splint to hold the pen, she must have adequate body function, in this case, fair or better muscle strength in her radial wrist extensors. However, Karen must also have adequate performance skills including the motor skills to exert enough force to adequately write her name, the cognitive or discerning skills to select a type of pen that requires minimum effort to operate, and the communication/social skills to ask sales personnel for a firm writing surface (clipboard) for her lap to compensate for the inaccessibility of the checkout counter.

The mental functions group includes affective, cognitive, and perceptual abilities. This group also includes the experience of self and body image (see Chapters 6, 25, and 26). A client, such as Karen, who has sustained a physically disabling injury, frequently may have an altered self-concept, lowered self-esteem, depression, anxiety, decreased coping skills, and other problems with emotional functions following the injury¹⁸ (see Chapter 6). Sensory functions and pain are also included in the body functions category (see Chapters 23 and 28). Neuromuscular and movement-related functions refer to the available strength range of motion and movement (see Chapters 19 through 22) but do not refer to the client’s application of these factors to activities or occupations as was seen in the example of Karen signing a credit card receipt as part of engaging in the occupation of shopping. The body functions category also refers to the ability of the cardiovascular, respiratory, digestive, metabolic, and genitourinary systems to function to support client participation. These are further described in both the OTPF-2 and the ICF. The reader is referred to the OTPF-2 Table 2 for a more detailed description of each function included in this category.

The Occupational Therapy Process

As described at the beginning of this chapter, the OTPF-2 consists of two parts: the domain and the process (Figure 1-2). From a very general perspective, the domain describes the scope of practice or answers the question “What does an occupational therapist do?” The process describes the methods of providing occupational therapy services or answers the question “How does an occupational therapist provide occupational therapy services?”

The process is briefly outlined here for continuity but the reader is referred to Chapter 3 for a more in-depth discussion. The primary focus of the OTPF-2 process is evaluation of the client’s occupational abilities and needs to determine and provide services (intervention) that foster and support occupational performance (outcomes).

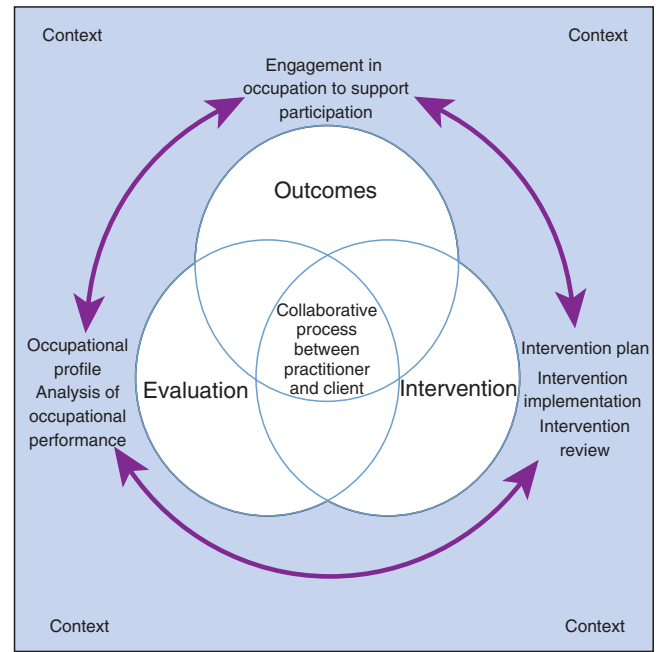

FIGURE 1-2 Occupational therapy process.

(From American Occupational Therapy Association: Occupational therapy practice framework: domain and process, *Am J Occup Ther* 62(6):625-688, 2008.)

Throughout the process the focus is on occupation; the evaluation begins with determining the client’s occupational profile and occupational history. Preferred intervention methods are occupation based and the overall outcome of the process is the client’s health and participation in life through engagement in occupation.

Interventions also vary depending on the client—whether person, organization, or population. In the practice of occupational therapy with adults with physical disabilities, the term *client*—at the person or individual level—may vary depending on the treatment setting or environment. In a hospital or rehabilitation center the person might be referred to as a *patient*, whereas in a community college poststroke program the person receiving occupational therapy may be referred to as a *student*. The term *client* or *consumer* might best describe the person who receives occupational therapy intervention at a center for independent living where the individual is typically living in the community and seeking intervention for a specific self-identified problem or issue.

Types of Occupational Therapy Intervention

Table 1-1 shows the types of occupational therapy intervention typically used in physical disability practice and their relationship to the domain of occupational therapy. Five general categories of intervention are presented in the OTPF-2: (1) therapeutic use of self, (2) therapeutic use of occupations and activities, a category composed of preparatory methods, purposeful activity, and occupation-based

■ **TABLE 1-1 | Types of Intervention**

Type of Intervention	Description
1. Therapeutic use of self	OT uses own self and all that entails (knowledge, personality, and experience), conveying empathy and active listening, and establishing trust
2. Therapeutic use of occupation and activity	Occupations and activities selected for specific clients that meet therapeutic goals
a. Occupation based	The client engages in the occupation and activities
b. Purposeful activity	The client learns and practices parts or portions of activity
c. Preparatory method	Methods that prepare the client for purposeful or occupation-based activity
3. Consultation process	OT uses knowledge and expertise in collaborating with the client to identify problems and develop and try solutions; it is up to the client to implement final recommendation
4. Education process	OT shares knowledge and expertise about engaging in occupation with the client, but the client does not actually engage in the occupation during the intervention
5. Advocacy	Efforts directed toward promoting occupational justice and empowering clients to seek and obtain resources to fully participate in their daily life occupations

activity, (3) consultation process, (4) education process, and (5) advocacy. Because the OTPF-2 has occupation as its primary focus, it is deceptive to think of the types of interventions as being selected or provided in any type of linear or stepwise order on a continuum. Rather, the occupational therapist reflects on the client's goal of engagement in his or her preferred self-selected occupations and collaborates with the client in selecting the type, or types, of intervention the occupational therapist deems will most successfully facilitate achievement of the occupational goal.

Since the inception of the OTPF and continued in the OTPF-2, the previous concept of intervention levels has been dismissed in favor of viewing them as types of intervention in which no one type is considered of less or more importance than another, but rather each has a potential contribution in facilitating the ultimate goal of supporting health and participation in life through engagement in occupation.

OT Practice Note

Throughout the OT process, the therapist should convey to the client that together they will select the outcomes based on the client's choice and collaborate in planning the intervention, thus establishing the beginnings of an atmosphere of caring and trust.

Therapeutic Use of Self

The OTPF-2 describes the therapeutic use of self as “A practitioner's planned use of his or her personality, insights, perceptions, and judgments as part of the therapeutic process” (p. 653).² Occupational therapy literature describes an OT who successfully uses therapeutic use of self for

Threaded Case Study

Kent and Karen, Part 4

Though Kent did not previously regard therapeutic use of self as an OT intervention, he has valued it highly and uses it in his practice. Clients respond well to Kent's caring and gentle approach. He enjoys the personal and interactive aspects of the therapeutic relationship, shows genuine interest in his clients' histories, actively listens to their responses, and makes it a practice to introduce himself and his role to his clients as the first step in the process. This practice allows Kent to assert the primacy of the client and associate and integrate the new information he is learning about the client with the image of the person he has just met.

Kent used therapeutic use of self as a type of intervention throughout the occupational therapy process with Karen. He brought to the process his 25 years of experience and knowledge of SCI as well as his experiential lessons of providing successful and not-so-successful OT intervention with numerous clients. Kent's college roommate and subsequent best friend has a physical disability, which has served to increase Kent's understanding and inform his attitudes and beliefs toward the experience of having a disability. His close and loving relationships with his sisters, wife, and teenage daughters provide him with an increased awareness of women's concerns and issues and cause him to consider how disability might be experienced differently by his women clients than by his men clients. All of these aspects of Kent's personal and professional repertoire support his ability to employ therapeutic use of self as an effective intervention in Karen's OT process.

intervention as having the qualities or attributes of showing empathy (including sensitivity to the client's disability, age, gender, religion, socioeconomic status, education, and cultural background), being self-reflective and self-aware, and being able to communicate effectively using active listening

and consistently keeping a client-centered perspective that in turn engenders an atmosphere of trust.^{5,8,17}

The very focus of the occupational therapy process provides a favorable context to support the OT's use of therapeutic use of self as intervention. By using a client-centered approach and beginning the process with an evaluation that seeks information about the client's occupational history and occupational preferences, the therapist's initial interactions with the client are characterized to the client as being interested in what the client does (occupational performance), who the client is (contexts and environments, and client factors such as values, beliefs and spirituality), and what occupations give meaning to the client's life.

Therapeutic Use of Occupations and Activities

This category of occupational therapy intervention in the OTPF was adapted from the section "Treatment Continuum in the Context of Occupational Performance" (Chapter 1, p. 7) in the fifth edition of this book. The category is defined in the OTPF-2 as "Occupations and activities selected for specific clients that meet therapeutic goals. To use occupations/activities therapeutically, context or contexts, activity demands, and client factors all should be considered in relation to the client's therapeutic goals" (p. 653).² Specific activities considered to be representative of the category, therapeutic use of occupations and activities, are further separated into three types including occupation-based intervention, purposeful activity, and preparatory methods that will each be discussed here.

Occupation-Based Intervention

In the OTPF-2, the purpose of occupation-based intervention is described as allowing "clients to engage in client-directed occupations that match identified goals" (p. 653).² Reading this description, Kent considers that occupation-based intervention would include providing intervention to promote engagement in all areas of occupation including ADL, IADL, rest and sleep, education, work, play, leisure, and social participation. Most of the occupational therapy intervention for Karen was occupation-based activity. To reach her targeted goal of resuming her favorite leisure occupation of clothes shopping, Kent and Karen took a trip to a nearby department store where Karen looked for a blouse with three-quarter-inch sleeves and a button-front closure. Karen perused the carousels inspecting the available blouses, asked for help from a salesperson, tried on blouses in the dressing room, made her selection, and paid for her purchase, all parts of a typical shopping excursion in a natural shopping environment. Kent demonstrated and gave suggestions when necessary for how Karen could perform some of the more difficult shopping activities, such as accessing the crowded carousels, negotiating her wheelchair into the dressing room from a narrow hallway, and transporting the hangers with blouses on her lap without having them slide to the ground.

Purposeful Activity

In this type of intervention "the client engages in specifically selected activities that allow the client to develop skills that enhance occupational engagement" (p. 653).² A few examples offered in the OTPF-2 document include "practices how to select clothing and manipulate clothing fasteners" and "role plays when to greet people and initiates conversation" (p. 653).² The description of the purpose and the examples offered caused Kent to reframe or slightly reconfigure his view of what purposeful activity entailed. Given the OTPF-2 categorization, he considered that he was providing purposeful activity intervention when he had Karen practicing activities that she would encounter as part of the occupation-based activity of clothes shopping. In the OT clinic, prior to the shopping trip, Karen and Kent collaborated on her being able to perform the purposeful activities of tearing checks out of her checkbook, accessing her credit card from her wallet, using a button hook to button her sweater, and lifting clothes on hangers out of a closet. Some of the shopping activities she encountered while buying her blouse were learned as part of other occupation-based interventions such as wheelchair mobility, writing, and dressing. When using purposeful activity, the OT practitioner is concerned primarily with assessing and remediating deficits in performance skills and performance patterns.

Preparatory Methods

Using intervention that is in nature preparatory, "the practitioner selects directed methods and techniques that prepare the client for occupational performance. It is used in preparation for or concurrently with purposeful and occupation-based activities" (p. 653).² Preparatory methods used by occupational therapy may include exercise, facilitation and inhibition techniques, positioning, sensory stimulation, selected physical agent modalities, and provision of orthotic devices such as braces and splints. Occupational therapy services for persons with physical disabilities often introduce these methods and devices during the acute stages of illness or injury. When using these methods, the occupational therapist is likely to be most concerned with assessing and remediating problems with client factors such as body structures and body functions. It is important for occupational therapists to plan the progression of this type of intervention so that the selected methods are used as preparation for purposeful or occupation-based activity and are directed toward the overarching goal of supporting health and participation in life through engagement in occupation.

Kent reflected that in preparation for Karen's occupation-based intervention of clothes shopping he used several interventions that would be considered preparatory methods. For example, he and Karen looked at her options for grasping items and decided on a tenodesis hand splint, using orthotics as an intervention. To use the splint more effectively she had to have stronger wrist extensors and, to push her wheelchair or to reach for and lift hangers with clothes,

she needed stronger shoulder muscles; thus, the preparatory intervention of exercise was chosen to facilitate ultimate engagement in purposeful and occupation-based activities.

Consultation Process

Consultation is not a new activity or service provided by OT but is now viewed or labeled as an intervention and situated or integrated into what is considered part of the occupational therapy process. It is defined as “a type of intervention in which practitioners use their knowledge and expertise to collaborate with the client. The collaborative process involves identifying the problem, creating possible solutions, trying solutions, and altering them as necessary for greater effectiveness. When providing consultation, the practitioner is not directly responsible for the outcome of the intervention” (p. 113).¹⁰

As Kent studied this description, he considered that throughout his career he has provided occupational therapy services that he would now regard as consultative in nature as described in the OTPF-2. For example, Kent provided consultation with a small chain of grocery stores where he assessed the accessibility and made recommendations to help them reach compliance with the guidelines of the Americans with Disability Act (ADA) (see [Chapter 15](#)). Based on his extensive knowledge of the ADA and his expertise in the activity demands for grocery shopping, his recommendations included suggestions for accessible parking and store layout, arrangement of shelves, adaptive equipment to enhance the shopping activity for people with a variety of disabilities, employee training to increase awareness of the shopping needs of people with disabilities, and many other ideas for streamlining the shopping experience for this population. After Kent completed the report of his recommendations and shared them with his client (the owners of the grocery store chain/organization) he had completed his OT intervention and it was up to the client to implement his suggestions. Many of Kent’s clients with SCI could potentially benefit from the implemented suggestions he had made, but this is not part of the consultation process intervention. With Karen’s family he provided consultation intervention (on an individual or person level) when he gave them advice regarding what specifications to look for in an accessible apartment for Karen.

Education Process

The OTPF-2 describes education process as a “type of intervention process that involves the imparting of knowledge and information about occupation and activity and that does not result in the actual performance of the occupation/activity” (p. 654).² Kent also considered this definition, thinking of instances when he provided this type of intervention. Most recently, with Karen, he responded to her concerns about returning to her job as an administrative assistant. She was having misgivings about the amount of physical work and energy involved; the modest amount of salary she received, which barely covered her preinjury

expenses; and the additional expenses she would have for personal and household assistance. Using his years of knowledge and experience, Kent provided intervention in the form of educating Karen about her options by informing her about the services offered by vocational rehabilitation and educating her about the possibilities and opportunities for further education to support her work goal of becoming an attorney, a job position, he pointed out, that held potential for higher pay and one that could be less physically demanding than her administrative assistant position. He informed her about the similar circumstances of some of his former clients, describing the various scenarios and outcomes of each (being mindful to preserve the former clients’ anonymity and privacy), as well as using his wealth of experience to discuss the many resources available to facilitate such options. Karen was already preparing to resume her job (an occupational goal she prioritized) and was actively participating in OT by engaging in occupation-based activity that involved her actual work occupations and supporting activities. The education process intervention described, however, provided her knowledge of options but did not involve any actual performance of an activity during the intervention. Kent could use the same education intervention process with Karen’s vocational counselor as well as with the law firm for which Karen is employed.

The intervention type identified as advocacy is provided when efforts are directed toward promoting occupational justice (access to occupation) and empowering clients to seek and obtain resources to fully participate in their daily life occupations (p. 654).² Kent worked with Karen and Karen’s work supervisor to advocate to the law firm partners for reasonable accommodations to support Karen’s continued employment. After a year of Karen’s successful job performance, Kent was invited to the state bar association conference to advocate for similar collaborations on behalf of other employees with disabilities.

Having studied the OTPF domain, process, and types of interventions and reinforcing his learning through application of his new knowledge to his own circumstances and those of his client Karen, Kent still felt the need for some additional suggestions or strategies for learning the OTPF more thoroughly. The next section explores these strategies.

Strategies for Learning the OTPF-2

The most effective first step in learning the OTPF-2 may be to obtain and thoroughly read the original document, making notations as points arise, drawing diagrams for increased understanding, writing questions or observations in the margins, and consulting tables, figures, and the glossary when directed, to reinforce or explicate new learning. The OTPF-2 is a comprehensive conceptualization of the profession that requires a substantial investment of time and commitment to study and apply to practice before one feels comfortable in its use. [Box 1-1](#) provides an abbreviated list

■ Box 1-1

Occupational Therapy Practice Framework Quick Guide

Supporting Health and Participation in Life through Engagement in Occupation: OT's unique contribution, the *overarching theme of the domain and the *overarching outcome of the process

Framework composed of two interrelated parts: Domain and Process

Domain = What OTs do—no single aspect considered more critical than another

Performance in areas of occupation (ADL, IADL, rest and sleep, education, work, play, leisure, social participation)

Client factors (values, beliefs, and spirituality, body functions, body structures)

Activity demands (space demands, social demands, sequencing and timing, required actions, required body functions, required body structures)

Performance skills (motor and praxis, sensory perceptual skills, emotional regulation skills, cognitive skills, communication and social skills)

Performance patterns (habits, routines, roles, rituals)

Context and environment (cultural, personal, temporal, virtual, physical, social)

Process = how OTs provide their services—collaborative process between client and OT

Evaluation (occupational profile, analysis of occupational performance)

Intervention (preferred term over *treatment*—includes intervention plan, intervention implementation, intervention review)

Outcomes (all goals aimed at the overarching goal of supporting health and participation in life through engagement in occupation)

Client = recipient of OT services (preferred term but actual term varies by practice setting—could be patient, student, consumer, employees, employer)

Individual (broad view of client—could be actual person with a disability or individual providing support for the client such as family, caregiver, teacher, or employer, who also may help or be served indirectly)

Organization (such as businesses, industries, agencies)

Populations (within a community)

Client-centered approach—an approach to the evaluation and provision of the intervention with emphasis on the client and his or her goals

Occupation versus activity—*activities* are characterized as being meaningful and goal directed but not of central importance to the life of the individual, whereas *occupations* are viewed as activities that give meaning to the person's life, contribute to one's identity, and those to which the individual looks forward to engaging; in the OTPF-2, the term *occupation* encompasses *activities*

Engagement = includes both the subjective (emotional or psychological) and objective (physically observable) aspects of performance

Types of Intervention

Therapeutic use of self—OT uses own self and all that entails (knowledge, personality, experience), conveying empathy, active listening, establishing trust

Therapeutic use of occupations and activities

- Occupation-based activity—client engages in the occupation
- Purposeful activity—client learns and practices parts or portions of occupations
- Preparatory methods—methods that prepare client for purposeful or occupation-based activity

Consultation process—OT uses knowledge and expertise collaborating with client to identify the problem and to develop and try solutions; it is up to the client to implement final recommendation

Education process—OT shares knowledge and expertise about engaging in occupation with the client, but the client does not actually engage in the occupation during the intervention

Advocacy—promotes occupational justice and empowers clients to resources for full participation in occupation

of some of the core terminology and concepts of the Framework to serve as a quick reference or to jog the reader's memory when first learning and using the OTPF.

More experienced occupational therapists who are accustomed to using the first iteration of the OTPF will find it helpful to consult the comparison of terms section, Table 11: Summary of Significant Framework Revisions, on pages 665-667 at the end of the *AJOT* article on the OTPF-2,² where terminology used in the Framework II is compared to that of the original OTPF. For those occupational therapists who are still using the UT-III, another, lengthier article titled "From UT-III to the Framework: Making the Language Work"⁹ similarly compares the three documents. Both articles provide helpful tables showing the language of the UT-III, the OTPF counterpart, and that of the ICF. For example, one section of this table shows Performance Area

(UT-III), Performance in Areas of Occupation (OTPF), and Activities and Participation (ICF), giving indications of the specific language used by each to name similar constructs. The occupational therapist can easily find the previous or older designation in one column, consider the new replacement terminology of the OTPF in another column, and locate the corresponding term from the ICF in yet another column.

Several pioneering authors wrote helpful articles demonstrating application of the OTPF for the various AOTA special interest sections (SIS). Siebert, writing for the Home and Community Health SIS, encouraged that it is "not as important to learn the OTPF as to use it as a tool to communicate practice, to support practice patterns that facilitate engagement in occupation, and to reflect on and refine our practice" (p. 4).²⁰ She also pointed out the dominant

role that context plays in home and community practice by providing continuity to the client, noting how firmly the OTPF supports this concept. She expressed her belief that the focus of the Framework on occupation and the beginning of the process with the client's occupational profile ensures that the results of OT intervention will matter to the client.²⁰

Coppola, writing for the Gerontology SIS, described how the Framework can be applied to geriatric practice and explained that the evaluation is one of OT's most powerful ways of informing others (including clients and colleagues) what OT is and what OT does. She provided a working draft of an Occupational Therapy Evaluation Summary Form that was developed to incorporate the OTPF and highlight occupation in a visual way into her practice in a geriatric clinic. The draft is unconstrained by the more traditional documentation forms that seem to bury occupation under diagnostic and clinical terminology.⁶

Similarly, Boss offered readers of the Technology SIS his reflection on how the Framework can be operationalized in an assistive technology setting. Addressing each of the categories of the domain, he offered examples of how assistive technology supports engagement in occupation (allowing completion of an activity or occupation) and how the use of assistive technology (personal device care and device use) can be an occupation in, and of, itself. He concluded his article by pointing out that “assistive technologies are all about supporting the client's participation in the contexts of their choice and are therefore part of the core of occupational therapy” (p. 2).⁴

Another strategy intended to facilitate the reader's education in the OTPF is the format of the chapters in this book as described next.

The OTPF-2: Its Use in This Book

In keeping with the OTPF-2's central focus on the client and the importance of contexts and participation in occupation, each chapter begins with a case study and then integrates the information presented with consideration of that client and circumstances, similar to the use of Kent and Karen's experiences as described and threaded throughout this chapter. As the particular content information is presented, the reader is frequently asked to reflect back to the case scenario and consider how the information applies to the specifics of the client portrayed. The probative questions asked at the conclusion of the initial portion (or Part 1) of the chapter's case study are also answered throughout the text or addressed at the end of the chapter.

Summary

“The Occupational Therapy Practice Framework,” the original (2002) and the revised “Occupational Therapy Practice Framework,” Second Edition, were developed by the profession to reassert its focus on occupation and clearly

articulate and enhance the understanding of the domain of occupational therapy (what OT practitioners do) and the occupational therapy process (how they do it) to both internal audiences (members of the profession) and external audiences (clients, healthcare professionals, and interested others). The overarching goal of Framework II is to support health and participation in life through engagement in occupation, which emphasizes the primacy of occupation, regarding it as both the theme of the domain and the outcome of the process.

The domain includes six categories that constitute the scope of occupational therapy, including performance in areas of occupation, performance skills and performance patterns, contexts, activity demands, and client factors. The OT process involves three interactive phases of occupational therapy services including evaluation, intervention, and outcomes, which occur in a collaborative and nonlinear manner. The types of occupational therapy intervention included in the Framework II and typically employed in physical disabilities practice settings include therapeutic use of self, therapeutic use of occupations and activities (including occupation-based activity, purposeful activity, and preparatory methods), consultation process, education process, and advocacy. In addition to studying the chapter, readers are encouraged to explore the AOTA's OTPF-2 document in its entirety and reinforce their learning by applying Framework II to their own life experiences and those of the clients they encounter in the case studies presented throughout the chapters of the book as well as those they experience in the clinic.

Review Questions

1. Briefly describe the history of the evolution of the “Occupational Therapy Practice Framework,” Second Edition.
2. Describe the need for the OTPF-2 in the practice of occupational therapy for persons with physical disabilities.
3. Describe the fit between the OTPF-2 and the ICF and how they inform and enhance the occupational therapist's understanding of physical disability.
4. List and describe the components that make up the occupational therapy domain, and give examples of each.
5. List and describe the components that make up the occupational therapy process, and give examples of each.
6. Briefly describe the occupational therapy intervention levels, and give an example of each as it might be used in a physical disability practice setting.

movement

■ Learning Objectives *After studying this chapter, the student or practitioner will be able to do the following:*

1. Trace the ideas, values, and beliefs that have influenced the development of occupational therapy as a profession.
2. Analyze the development of occupational therapy within the larger context of cultural, social, political, and legislative forces.
3. Explain how some of the opportunities and challenges that physical disabilities practitioners face today are a result of the way the history of occupational therapy has evolved.

Roots of Occupational Therapy

Even into the early 20th century, individuals with physical disabilities “were kept at home, out of sight, in back bedrooms, by families who felt a mixture of embarrassment and shame about their presence” (p. 29).¹⁷ This detrimental and

pervasive reaction to physical disability began to change with the introduction of the medical model. From a medical perspective, disability was seen as a biologic deficit that could be ameliorated with professional treatment. In fact, in the early 20th century, “progressive reformers” were looking to medical professionals to assist individuals with

disability to reclaim their place in the community and the workplace.⁵¹ It was against this backdrop that the profession of occupational therapy was founded in 1917.

The founders of occupational therapy believed that they could help to rehabilitate individuals with disability through engagement in occupation. They chose the term *occupational therapy* to reflect this goal, because in 1917 *occupation* was commonly used to mean “being occupied or employed with, or engaged in something” (p. 682).³⁵ At the time, the founders were aware that such broad terminology could be confusing.¹⁴ However, they valued the breadth of the term for the freedom it would give occupational therapists to use a wide range of modalities and approaches, individually tailored to meet each person’s desires and needs.

The founders included William Rush Dunton, a psychiatrist; Herbert J. Hall, a physician; Eleanor Clarke Slagle, a social welfare worker; Susan Johnson, a former arts and crafts teacher; Thomas Kidner and George Barton, both former architects; and Susan Tracey, who was a nurse. They were influenced in their views of occupational therapy by ideas and beliefs prevalent during the latter part of the 19th century and the early years of the 20th century. The ideas that seemed to have most shaped the profession’s early development were reflected in three movements: moral treatment, arts and crafts, and scientific management.

Moral Treatment

Moral treatment originated in 19th century Europe and was promoted by physicians such as Philippe Pinel of France and Samuel Tuke of England. It represented a shift in thinking from a pessimistic viewpoint that labeled the mentally ill as subhuman and incurable to an optimistic one that viewed the mentally ill as capable of reason and able to respond to humane treatment. The main features of moral treatment included a respect for human individuality, an acceptance of the unity of mind and body, and a belief that a humane approach using daily routine and occupation could lead to recovery.⁸ Occupations included music, physical exercise, and art³⁹ and agriculture, carpentry, painting, and manual crafts.¹³

Building on these ideas half a century later, the famous neuropsychiatrist Adolf Meyer proposed that many illnesses were “problems of adaptation” that could be remedied through involvement in curative occupations.³¹ Dunton and Slagle enthusiastically supported this view, and Meyer’s philosophy of “occupation therapy” was published in the first issue of the profession’s journal. Slagle, who worked with Meyer at Phipps Clinics, developed habit training programs in mental hospitals to reestablish healthy habits of self-care and social behavior.⁴³

Arts and Crafts

The rise of the *arts and crafts movement* in the 1890s was in reaction to the perceived social ills created by the Industrial Revolution.¹⁰ The economy was changing from an agrarian to a manufacturing society, so that what had

previously been made by hand was now produced in factories. Proponents of the arts and crafts movement asserted that this resulted in a society of dissatisfied workers who were bored by monotonous and repetitive working conditions.

The use of arts and crafts as a therapeutic medium in occupational therapy (OT) arose from this trend. The arts and crafts approach was based on the belief that craftwork improved physical and mental health through exercise and the satisfaction gained from creating a useful or decorative article with one’s own hands. According to Johnson, the therapeutic value of handicrafts lay in their ability to provide occupation that stimulated “mental activity and muscular exercise at the same time.”²⁴ Different handicrafts could also be graded for the desired physical and mental effects. During World War I, OT reconstruction aides successfully used crafts for the physical and mental restoration of disabled servicemen.⁴¹ For treating tuberculosis, Kidner advocated a graduated approach that began with bedside crafts and habit training and proceeded to occupations related to shop work and ultimately actual work within the institution.²⁶

Thus, the ideas from the moral treatment and arts and crafts movements became intertwined as a definition of OT evolved to include treatment of individuals with physical and mental disabilities. In its early years, occupational therapists worked with patients throughout three stages of recovery.²⁶ During convalescence, patients would engage in bedside occupations that primarily consisted of handicrafts such as embroidery and basket weaving. Once patients were able to get out of bed, they would engage in occupations designed to strengthen both body and mind, such as weaving or gardening, and occupations designed to reestablish basic habits of self-care and communication. When they were almost ready to return to the community, patients would engage in occupations that would prepare them for vocational success, such as carpentry, painting, or manual crafts.

Scientific Management

Frederick Taylor, a prominent engineer, introduced his theory of *scientific management* in 1911.⁴⁶ He proposed that rationality, efficiency, and systematic observation could be applied to industrial management and to all other areas of life, including teaching, preaching, and medicine. Progressive reformers of the period advocated that the ideology of scientific management address societal problems such as poverty and illness. These reformers criticized the noisy, dirty asylum of the 19th century and urged that the image of medical care be transformed into the clean, efficient hospital.²³ The idea that knowledge could be developed through research and observation and applied to patient care became an underlying tenet of the science of medicine and ultimately resulted in the development of reliable protocols for surgical and medical interventions.⁵¹

The founders of OT were attracted to the idea of a scientific approach to treatment. Barton was particularly taken with Taylor's time and motion studies and thought they might provide a model for OT research.⁷ Dunton advocated that those who entered the profession be capable of engaging in systematic inquiry in order to further the profession's goals.¹⁵ Similarly, Slagle urged research in OT to validate its efficacy.⁴³ By 1920 the profession was promoting the notion of the "science" of occupation by calling for "the advancement of occupation as a therapeutic measure, the study of the effects of occupation upon the human being, and the dissemination of scientific knowledge on this subject."¹¹

However, there is little in the OT literature of the early 20th century to suggest that OT practice was informed by systematic observation. One exception was the Department of Occupational Therapy at Walter Reed Hospital in Washington, D.C., under the direction of psychologist Bird T. Baldwin.⁶ OT reconstruction aides were assigned to the orthopedic ward, where methods of systematically recording range of motion and muscle strength were established. Activities were selected based on an analysis of the motions involved, including joint position, muscle action, and muscle strengthening. Methods of adapting tools were suggested, and splints were fabricated to provide support during the recovery process. Treatment with this systematic approach was more narrowly focused at times but was applied within the context of what Baldwin called "functional restoration," in which OT's purpose was to "help each patient find himself and function again as a complete man [sic] physically, socially, educationally, and economically."⁵

Besides advocating a scientific approach to practice, the scientific management ideology emphasized efficiency and a mechanistic approach to medical care. Using the factory analogy, patients were the product, and nurses and therapists were the factory workers. It was assumed that doctors had the most scientific knowledge and therefore should be positioned at the top of the medical hierarchy. Dunton, a physician himself, seemed to support this arrangement: "The occupational therapist, therefore, has the same relation to the physician as the nurse, that is, she is a technical assistant."¹² As the profession evolved, an emphasis on efficiency and deference to medical authority became problematic for the profession. The focus on science and the resulting growth of the medical model were both beneficial and detrimental to OT practice.

Expansion and Specialization

The Rehabilitation Model

The growth of the *rehabilitation model* began after World War II and peaked with the healthcare industry boom in the 1970s, following the passage of bills establishing Medicare and Medicaid. Although this growth was initially driven by the need to treat the country's wounded soldiers,

care of injured and chronically ill civilians also became a concern.

World War II revived the need for the United States to provide medical care for its wounded soldiers. Many more soldiers survived than in World War I because of recent scientific discoveries such as sulfa and penicillin. The Second World War also highlighted the value of OT services: "Although occupational therapy started during the last World War, it developed slowly [until] now when doctors are finding this aid to the sick and wounded invaluable."³³ A major effort was launched to reorganize and revitalize the Veterans Administration (VA) hospital system. Departments of physical medicine and rehabilitation were created to bring together all the services needed to care for the large number of war injured:

The theory that handicapped persons can be aided by persons who understand their special needs originated during World War II. The armed services established such hospitals for disabled veterans such as the one for paraplegics in Birmingham California (originally built in 1944 in Van Nuys, CA as a cutting edge hospital for soldiers returning from the war, the former hospital is now a high school). They helped the morale and physical condition of the patients so much that others were built for civilians.³⁴

The interdisciplinary approach to care was emulated in the private sector. Demand for medical services increased in the civilian population as the treatment of chronic disability became a priority. Howard Rusk, a prominent voice in the development of rehabilitation medicine, asserted that the critical shortage of trained personnel would impede the country's ability to deliver services to the "5,300,000 persons in the nation who suffer from chronic disability."²⁵ He cited OT as one of the essential rehabilitation services. In response to the growing demand for rehabilitation services, Congress passed the Hill-Burton Act in 1946 to provide federal aid for the construction of rehabilitation centers. A proviso of the legislation was that rehabilitation centers must "offer integrated services in four areas: medical, including occupational and physical therapy, psychological, social, and vocational."⁵² The passage of legislation establishing Medicare and Medicaid in 1965 put further demands on rehabilitation services to serve the chronically ill and elderly within healthcare institutions, as well as the community.

Physical Dysfunction as a Specialty

The creation of a specialty in physical dysfunction within occupational therapy came about as a response to the changing demands of the marketplace and its requirement that specialists possess particular kinds of medical knowledge and technologic skills.²⁰ This new specialty began with an increasing focus on occupations that would promote physical strength and endurance:

The Army is death on the old-time invalid occupations of basket weaving, chair caning, pottery and weaving. These

are “not believed to be interesting occupation for the present condition of men in military service,” says an officer from the Surgeon General’s office. The stress now is on carpentry, repair work at the hospital, war-related jobs like knitting camouflage nets, and printing.⁴⁹

The scientific approach of joint measurement and muscle strengthening that Baldwin pioneered at the end of World War I was adopted and improved upon. Claire Spackman, who along with Helen Willard wrote the profession’s first textbook on occupational therapy, argued that therapists must become skilled in carrying out new treatments based on improved techniques. According to Spackman, the occupational therapists serving people with physical disability needed to be skilled in teaching activities of daily living (ADL), work simplification, and training in the use of upper extremity prostheses. But first and foremost, she asserted, “Occupational therapy treats the patient by the use of constructive activity in a simulated, normal living and/or working situation. . . . Constructive activity is the keynote of occupational therapy.”⁴⁴

As the rehabilitation movement helped to establish the importance of OT, it further positioned the profession within the *medical model*. OT was urged to specialize and separate into two distinct fields, physical dysfunction and mental illness. The head orthopedist at Rancho Los Amigos Hospital in Downey, California, argued that the separation would result in “strengthened treatment techniques” and thus more credibility among the medical profession, which “does not recognize your field as an established necessary specialty.”²² The American Occupational Therapy Association sought closer ties with the American Medical Association in order to increase occupational therapy’s visibility and reputation as a profession dedicated to rehabilitation of the individual through engagement in occupation.

The closer relationship with medicine probably helped the profession gain credibility, at least within the medical model. The positive aspect of the medical model is that it emphasized the importance of the rehabilitation of those with disabilities, and it helped stimulate the development of new scientific techniques. The negative aspect of the medical model is that it presumed that the individual is a passive participant in the process. In response to this view, a new social model was proposed that placed the individual at the center of the rehabilitation process.

A New Paradigm of Disability: Disability Rights/Independent Living Movements

The advocacy for disability rights that took hold in the 1970s had its roots in the social and political activism of the 1960s. During the 1960s, disabled people were profoundly influenced by the social and political upheaval that they witnessed. They identified with the struggles

of other disenfranchised groups to achieve integration and meaningful equality of opportunity. They learned the tactics of litigation and the art of civil disobedience from other civil rights activists. They absorbed reform ideas from many sources: consumerism, demedicalization, and de-institutionalization (pp. 15-16).¹⁶

Like the civil rights and women’s movements, the *disability rights movement* was rooted in self-advocacy. That is, it was the individuals with disability themselves who were promoting their own cause. Their activism took many forms including lawsuits, demonstrations, founding of a plethora of organizations dedicated to achieving disability rights, and political lobbying for legislation to address inequality and protect rights.

The ideas underlying the disability rights movement were based on a social rather than a medical model. The medical model had provided the predominant view of individuals with disability for much of the 20th century. It placed the medical professional at the center of the rehabilitation process and the patient on the periphery as the person who was being helped by the experts. It categorized individuals according to their medical disability (e.g., the paraplegic or the quadriplegic), and it saw the remediation of that medical condition as the way to eradicate disability. Disability rights advocates rejected this view as too paternalistic, passive, and reductionistic. Instead they advocated a paradigm that put the individual with disability at the center of the model as the expert in knowing what it was like to have a disability.

The *social model* proposed that disability was created because of environmental factors that prevented individuals from being fully functioning members of society. Physical boundaries prevented individuals from having access to schools, workplace, and home. Social views of individuals as pathetic cripples blocked full participation in life activities. Political and legal interpretations advocated “separate but equal” participation rather than inclusion. The social model argued that disability must be viewed from a cultural, political, and social lens rather than a biomedical one:

This [biomedical] model makes us aware that a complex system of mutually supporting beliefs and practices can impact those with disability by: stigmatizing them as less than full humans, isolating them by policies of confinement or the built environment, making them overly dependent on professionals rather than helping them develop responsible behaviors, robbing them of independent decision making that others enjoy, undermining their self-confidence in their many capabilities, over-generalizing the significance of some impairment, and defining them as tax-eaters rather than tax-contributors (p. 22).⁴⁵

Aligning itself with the social model, the *independent living movement* got its start when Edward Roberts was admitted to the University of California, Berkeley, in fall 1963.⁴⁵ The polio that Roberts had contracted at the age of

14 left him paralyzed from the neck down and in need of a respirator during the day and an iron lung at night. It was arranged that Roberts would stay in Cowell Hospital on the Berkeley campus with his brother Ron providing him personal assistance. Although Roberts was the first, in the following years Berkeley admitted other students with severe disabilities. They formed the “Rolling Quads” and were dedicated to making the campus and environs physically accessible.

Having completed his master’s degree, Roberts, and his fellow Rolling Quads, were invited in 1969 to Washington to help develop a program aimed at retention of students with disability on college campuses. They created the Physically Disabled Students’ Program (PDSP), which included provision for personal assistants, wheelchair repair, and financial aid. In 1972 Roberts became the first executive director of the first Center for Independent Living (CIL), located in Berkeley. Roberts based the CIL on the principles underlying the PDSP:¹ “that the experts on disability are the people with the disabilities;³ that the needs of the people with disabilities can best be met by a comprehensive, or holistic program, rather than by fragmented programs at different agencies and offices;⁴ that people with disabilities should be integrated into the community” (p. 61).³⁷ Since the founding of the first CIL, hundreds of other centers have been developed throughout the country.

The Tension between Paradigms: An Ongoing Discussion within the Profession

Moral Treatment versus the Medical Model

In the 1960s and 1970s, the tension between paradigms within occupational therapy was expressed in terms of moral treatment versus the medical model. A cry arose from some of the profession’s leaders to return to its roots in moral treatment and to forego what Shannon referred to as the “technique philosophy.”⁴² In his article on what he called “the derailment of occupational therapy,” Shannon described two philosophies at odds with each other. One, he asserted, viewed the individual “as a mechanistic creature susceptible to manipulation and control via the application of techniques”; the other, based on the profession’s early philosophy of moral treatment, emphasized a holistic and humanistic view of the individual.

Kielhofner and Burke described the situation as a conflict between two paradigms.²⁷ Early OT practice, they asserted, was based on the paradigm of occupation that had moral treatment as its foundation. This paradigm provided a “holistic orientation to Man [sic] and health in the context of the culture of daily living and its activities.” Post–World War II practice, they asserted, was based on the paradigm of reductionism, a mode of thinking characteristic of the medical model. This view emphasized the individual’s “internal states” and represented a shift in focus to “internal

muscular, intrapsychic balance and sensorimotor problems.” The authors acknowledged that practice based on the reductionist paradigm “would pave the way for the development of more exact technologies for the treatment of internal deficits”; however, they were concerned it “necessitate[d] a narrowing of the conceptual scope of occupational therapy.”²⁷

The claim that early OT practice was based on the humanistic and holistic philosophy of moral treatment is accurate, but it does not tell the full story. As this chapter describes, the founders also valued the medical model and the importance that “science” could play in establishing the profession’s credibility. For example, the Committee on Installations and Advice, directed by Dunton, was formed to scientifically analyze the most commonly used crafts and to match the therapeutic value of each craft to a particular disability.⁴⁰

How could the founders have supported what came to be viewed in the 1970s as the two opposing views of moral treatment and the medical model? The answer may be that in 1917 when the profession was founded, the models were not considered to be incompatible because the scientific medical model had not fully taken hold. It appears that in the founding years, OT primarily practiced moral treatment and talked about how practice should also be medical and scientific. When early practitioners were asked to treat patients in order to “restore the functions of nerves and muscles” or to make use of “the affected arm or leg,”⁴⁴ they based their treatment on their belief in the importance of occupation, habit training, and their knowledge of crafts. Once knowledge and technologic advances were sufficient and occupational therapists could actually practice using a scientific, medical perspective, it became apparent that the ideas underlying these two paradigms were in conflict.

The physical disabilities therapist was faced with the problem of how to give treatment that was, on the one hand, holistic and humanistic and, on the other, medical and scientific. Baldwin’s answer in 1919 was to see activities such as muscle strengthening and splint fabrication as techniques that contributed to the larger goal of “functional restoration” of the individual’s social, physical, and economic well-being.⁶ Spackman’s answer in 1968 was that the occupational therapist should use “constructive activity in a simulated, normal living and/or working situation. This is and always has been our function.”⁴⁴ She emphasized the teaching of ADL and work simplification and was critical of treatment that consisted of having patients sand or use a bicycle saw with no “constructive activity” involved.

Another answer to the question of differing paradigms was to move outside the medical model. Bockoven urged OT practitioners to set up services in the community based on moral treatment. He said:

It is the occupational therapist’s inborn respect for the realities of life, for the real tasks of living, and for the

time it takes the individual to develop his modes of coping with his tasks, that leads me to urge haste on the profession ... to assert its leadership in fashioning the design of human service programs. ... Don't drop dead, take over instead!⁹

Yerxa urged therapists not to rely solely on doctor's orders:

The written prescription is no longer seen by many of us as necessary, holy or healthy. ... The pseudo-security of the prescription required that we pay a high price. That price was the reduction of our potential to help clients because we often stagnated at the level of applying technical skills.⁵⁴

However, as practice moved into the 1980s, there was much concern that if occupational therapists did as their critics suggested, they would jeopardize reimbursement as well as referrals. They argued that they were being asked to exclude skills and knowledge they believed were valuable in patient treatment, such as exercise, splinting, and facilitation techniques. They further argued that many patients receiving OT services were initially not at the level of motor capability that would enable them to engage in satisfying occupations. It was proposed that adjunctive techniques such as exercise and biofeedback should be considered legitimate when used to prepare the patient for further engagement in occupation.⁵⁰ A study conducted in 1984 by Pasquinelli showed that although therapists valued occupation, they used a wide variety of treatment techniques and approaches, including facilitation and nonactivity-oriented techniques.³⁶ Both Ayres and Trombly argued that instead of attempting to redirect the focus of OT, the profession should include current clinical practices that had proved effective on an empirical and practical basis.^{4,50}

The Rehabilitation Model versus the Social Model

By the latter decades of the twentieth century, the debate became expressed as the conflict between the rehabilitation model and the social model. Scholars such as Gill¹⁸ brought the perspective of the social model of the disability rights advocates to the discussion of what constituted ideal occupational therapy practice.

She argued that the rehabilitation model exempted society from taking any responsibility for its role in creating the climate that restricted the rights and opportunities of the disabled. She urged occupational therapists to examine their practice and make sure that their treatment did not focus solely on the individual's physical condition.

For rehabilitation to be helpful, it must address the reality of what life is like for disabled persons. If rehabilitation professionals fail to fit their services to the patient's needs, values, and interests, they fail both the patient and their own professional aspirations. ... Without a proper balance

of physical treatment and realistic social information, rehabilitation cannot enable patients. ... What good are increased range of motion and finger dexterity when a patient's morale can be crushed by job discrimination or social rejection? (p. 54)¹⁸

A study conducted by Pendleton (1990) supported Gill's concerns. Pendleton found that occupational therapists were much less likely to provide training in independent living skills than physical remediation.³⁸ She defined independent living skills as "those specific abilities broadly associated with home management and social/community problem solving." She argued that "Mastering such skills could contribute to the achievement of control over one's life based on the choice of acceptable options that minimize reliance on others. ... The result of achieving such control is that the person can actively participate in the day-to-day life of the community" (pp. 94-95).³⁸ She recommended that if occupational therapists are not able to provide sufficient independent living skills training in inpatient rehabilitation centers, they should shift their treatment to community-based programs. Pendleton saw independent living skills as the essence of occupational therapy, and urged therapists to make it one of their priorities.

Longmore, a well-known historian and disability rights activist, emphasized the importance of the issues raised by Gill and Pendleton. Although he acknowledged that disability rights activism has been responsible for numerous pieces of legislation since the 1970s aimed at giving those with disability equal access to all parts of society including schools, work, public places, and transportation, he warned that there is still much to be done. The most important legislation passed during this period included the Rehabilitation Act of 1973, the Individuals with Disabilities Education Act of 1973 (IDEA), and the Americans with Disabilities Act of 1990 (ADA). However, Longmore argued, despite this legislation, people with disabilities continue to experience marginalization and financial deprivation. "Depending on age and definition of disability, poverty rates among disabled people range anywhere from 50 percent to 300 percent higher than in the population at large" (p. 19).²⁹ He worried that most people assume that the ADA has eradicated the major problems for those with disabilities, when in fact "to a surprising extent U.S. society continues to restrict or exclude people with disabilities" (p. 21).²⁹

Contemporary Practice: Addressing the Unintended Consequences of the Rehabilitation Model

As previously discussed, disability scholars like Longmore and Gill criticized the main premise of the rehabilitation model: that something is abnormal or lacking in the

individual with disability.^{19,30} The main justification for rehabilitation services is that through the intervention of professionals such as occupational therapists, the client can become more independent and a more useful contributor to society. The problem with this premise is that it assumes that clients want to become more “independent” (as defined by the rehabilitation specialists) and that they cannot fully contribute to society in their current condition. Thus, the rehabilitation model has the unintended consequence of devaluing persons with disabilities and placing the focus of intervention on remediating the disability rather than the social, political, and economic barriers that contribute to it. Kielhofner discussed this problem in the Special Issue on Disability Studies that appeared in the *American Journal of Occupational Therapy*: “As this paper and others in this special issue illustrate, disability studies raises issues and questions to which there are no easy answers” (p. 487).²⁸ He quotes the disability scholar Abberley, who notes that “OT, despite what may be the best of intentions on the part of its practitioners, serves to perpetuate the process of disablement of impaired people” (p. 487).²⁸

One answer is to create constructs that seek to blend the rehabilitation and social models by redefining disability. The World Health Organization sought to do this in their 2001 International Classification of Functioning, Disability and Health (ICF).⁵³ The ICF provides a classification that considers physical and mental impairments as well as environmental and personal factors, any or all of which may result in activity limitations and participation restrictions.

Based on the conceptual scheme of the World Health Organization, the American Occupational Therapy Association issued the Occupational Therapy Performance Framework (OTPF) in 2002 and its revision in 2008.^{1,2} It provides a construct that promotes client-centered engagement in occupation as the central focus of practice. This construct addresses issues raised by proponents of moral treatment, as well as the social and medical model. It reclaims the values of moral treatment by its focus on occupation-based treatment that is both holistic and humanistic. It integrates aspects of the medical model by advocating the reduction of functional impairments caused by physical and psychological limitations. Finally, it supports the social model of the disability rights movement by emphasizing the need for client-centered treatment within the context of the social, cultural, and political environment.

Another answer is for occupational therapists to continue to emphasize the therapeutic use of self in all relationships with clients. A focus on the importance of the therapist’s interaction with clients has been an underlying tenet of occupational therapy since its founding and continues today. Indeed, as Taylor et al. found in their survey of 568 occupational therapists, “Most therapists considered therapeutic use of self as the most important skill in occupational therapy practice and a critical element of clinical reasoning” (p. 204).⁴⁸ By focusing on the client-therapist

relationship, the practitioner is more likely to understand the client’s experience as an individual with a disability, and jointly formulate an intervention plan that centers on the client’s goals. When a viable therapeutic relationship is formed, practice is much more likely to be client-centered.

Scholarship focused on the disability experience can add to the profession’s body of knowledge and help to increase our understanding of how occupational therapy can address disability studies concerns. For example, research by occupational therapy scholars like Taylor,⁴⁷ Neville-Jan,³² and Guidetti, Asaba, Tham²¹ examines the experiences of those with disabilities through phenomenological and narrative accounts and thereby helps occupational therapists understand disability from the individual’s perspective.

Finally, a knowledge of history can provide a context from which to understand the current challenge to physical disabilities practice. As this history has demonstrated, early treatment in occupational therapy was based on belief in the importance of occupation, habit training, and knowledge of crafts. As scientific knowledge and technology advanced, OT defined a role for itself within the rehabilitation model. This resulted in the emergence of physical disabilities as a specialty within OT. The closer relationship with medicine helped the profession gain credibility. However, the scientific reductionism of the medical model put professional practice at odds with the holistic humanism of moral treatment. Today we discuss this in terms of the tensions inherent in the rehabilitation model versus the social model advocated by disability scholars. Our current challenge is to bridge the rehabilitation and social models wherever possible. Occupational therapy is uniquely qualified to do this because we were founded on two conflicting paradigms—the humanistic and the scientific—and therefore tension between two paradigms is not new for our profession. There have been ongoing discussions since the 1960s on how to bridge the tension between paradigms. These discussions have led the profession full circle, back to its most enduring belief: in the benefits of engagement in occupation. When occupational therapists keep occupation as the central focus, it is easier to find the intersection between the rehabilitation and social models.

As new approaches and techniques are developed in the future, OT intervention that promotes engagement in desired occupations will remain consistent with the philosophical base of the profession and help to further advance occupational therapy as a valued service in physical disabilities practice.

Using History to Understand Today’s Practice

In lieu of a case study, we will demonstrate how we can use our knowledge about occupational therapy’s history to answer a question that is prevalent among students and therapists today: Why do occupational therapists continually have to define *occupational therapy* to others?

First we should acknowledge that more people than ever do understand occupational therapy. Most of these people are individuals who have received treatment or have had personal contact with someone who received occupational therapy. So each time an occupational therapist successfully engages a client in treatment, he or she is providing a positive definition of occupational therapy. That being said, it can feel as though occupational therapists spend quite a bit of time educating others as to what we do. We can look back to the founding years to understand why this is so. The answer is complex and includes several factors.

The first relates to the profession's purpose. As this chapter describes, in naming the profession, the founders were looking for a term that was broad enough to encompass all of the things that occupational therapists did. The AOTA in 1923 described occupational therapy in this way: "Occupational Therapy is a method for training the sick or injured by means of instruction and employment in productive occupation. The objects sought are to arouse interest, courage, and confidence; to exercise mind and body in healthy activity; to overcome disability; and to re-establish capacity for industrial and social usefulness."³ This definition reflects a holistic, humanistic, and all-encompassing view of the individual, the rehabilitative process, and the role of occupational therapy within it. It addresses the mind as well as the body, and social as well as medical goals. The founders ultimately decided that *occupational therapy* was the term that best reflected the profession's goals. This is not to say that the founders did not consider the possible negative aspects of the term. It is clear from their writings that they were aware that such a broad term might cause some misunderstanding. However, in the end, they felt that this negative would be offset by the positive of providing occupational therapists with a wide range of freedom to treat each individual in the best way possible.

Second, we must consider that the name was chosen in 1917, and meanings of terms do change over time. For example, children with disabilities were placed in "asylums for the crippled" in the early 1900s. We would never use that terminology today. Fortunately, *occupation* does not carry such a negative connotation in today's lexicon, but the term has shifted in meaning. In 1917, *occupation* was most commonly used to mean an important activity in which one engages. For example, in a novel, one might read about a woman who was searching for an occupation that would satisfy her free time. As the century progressed, the term *occupation* came to be more closely aligned with the kind of paid work you do, as in "What is your occupation?" When looked at in this light, it is easier to understand any confusion someone today may have about the term, and the continual need for the occupational therapist to educate people about the term's meaning within today's context.

Third, we must also consider that the professions that exist today did not exist at the time of occupational

therapy's founding. That is one reason the definition of OT was so broad. At the time of the founding of occupational therapy, society was looking for a profession that could help remediate the wounds and illnesses of returning soldiers and enable them to become productive members of society. Occupational therapy offered that promise. Professions such as social work and physical therapy were still in their fledgling stage and it was unclear which profession would ultimately be involved in the soldiers' rehabilitation. In addition, art, music, recreation, and vocational therapy had yet to be introduced.

Finally, as has been discussed throughout this chapter, the ideas underlying occupational therapy do not fit neatly into just one theoretic paradigm. Occupational therapy uses an occupation-based, client-centered approach that bridges both the medical and social models, as is evidenced in the Occupational Therapy Performance Framework. Although this sounds good in theory, in practice it means that if occupational therapists are working with people who use a strict medical model (including third parties), there will be misunderstandings about OT's proper role. This is where occupational therapists must be proactive in describing what we do.

History tells us that occupational therapy has always had a humanistic, holistic approach to viewing its clients and its role, and it cannot be neatly confined to the medical or social paradigms. The blending of these paradigms by the ICF and OTPF finally offers occupational therapy a suitable home. However, these are new ideas and it will take time for them to be accepted. This is one more reason why occupational therapists will not be finished defining what we do any time soon. But is it not a worthy challenge? History would suggest that it is. So the next time you have to define occupational therapy, think of yourself as the latest generation to carry on the proud tradition of defining your goals by what is good for the client rather than what "fits" into the prevailing theoretical model.

Review Questions

1. Name the seven founders of occupational therapy, and list the professional background of each.
2. What ideologies shaped the development of occupational therapy in the late 19th and early 20th centuries?
3. What were the main features of the philosophy of moral treatment?
4. Describe the ideas that were the foundations of occupation as a remedy for mental and physical illness.
5. What provoked the rise of the arts and crafts movement?
6. How did the arts and crafts movement influence occupational therapy?
7. Describe scientific management. How did it influence the development of occupational therapy?

8. When did the rehabilitation model evolve? How did the world wars influence the development of the rehabilitation model?
9. How did physical dysfunction become a specialty?
10. What factors influenced occupational therapy to adopt the medical model?
11. What was the apparent conflict between moral treatment and the medical model?
12. What impact has the disability rights and independent living movement had on occupational therapy?
13. How is the apparent conflict between the medical model and the social model being resolved in occupational therapy practice?

■ **Learning Objectives** After studying this chapter, the student or practitioner will be able to do the following:

1. Identify and describe the major functions of the occupational therapy (OT) process.
2. Describe how clinical reasoning adjusts to consider various factors that may be present in the intervention context.
3. Identify how theories, models of practice, and frames of reference can inform and support OT intervention.
4. Identify appropriate delegation of responsibility among the various levels of OT practitioners.
5. Discuss ways in which OT practitioners may effectively collaborate with members of other professions involved in client care.
6. Recognize ethical dilemmas that may occur frequently in OT practice, and identify ways in which these may be addressed and managed.
7. Describe the various practice settings for OT practice in the arena of physical disabilities.
8. Discuss the type of services typically provided in these settings.
9. Identify ways in which different practice settings affect the occupational performance of persons receiving occupational therapy services.
10. Identify the environmental attributes that afford the most realistic projections of how the client will perform in the absence of the therapist.
11. Identify environmental and temporal aspects of at least three practice settings.
12. Describe ways in which the therapist can alter environmental and temporal features to obtain more accurate measures of performance.

Case Study
Sheena

Sheena is an occupational therapy student who began her first fieldwork internship 2 weeks ago. She felt fortunate to be assigned a site that provides a wide array of services. Sheena's site is a community hospital providing a continuum of care from emergency services and critical care (intensive care unit—ICU) to outpatient rehabilitation services. Her internship includes providing OT intervention in a variety of settings. Her clinical instructor (CI) requested that she review the process of developing an intervention plan and be prepared to differentiate the role of occupational therapy in the various settings.

Critical Thinking Questions

1. What process should be used when developing an intervention plan?
2. How do theories, models of practice, and frames of reference guide an intervention plan?
3. What forms of clinical reasoning are employed when providing occupational therapy services?

This chapter is divided into two sections. The first section introduces the occupational therapy (OT) process, summarizing the function of evaluation, intervention, and outcomes described in the Occupational Therapy Practice Framework, Second Edition (OTPF-2).⁵ The chapter will acquaint the reader with the complexity and creativity of clinical reasoning within the context of the contemporary clinical environment. The complementary roles of different occupational therapy practitioners, as well as relationships

between OT and the other professional disciplines involved in the care of the client with physical dysfunction, are described. Common ethical dilemmas are introduced and ways to analyze these are presented.

The second section describes various practice settings where occupational therapy services are provided for individuals who have physical disabilities with a discussion of typical services in each setting.

■ **SECTION 1 | The Occupational Therapy Process**

WINIFRED SCHULTZ-KROHN,
HEIDI MCHUGH PENDLETON

The Occupational Therapy Process

The OTPF-2 discusses both the domain and the process of the profession.^{5,83} The domain is described in Chapter 1, and the reader should be familiar with the domain prior to reading about the process of occupational therapy.

The occupational therapy process should be conceptualized as a circular process initiated by a referral (Figure 3-1). Following the referral, an evaluation is conducted to identify the client's occupational needs. The intervention is developed based on the evaluation results. The targeted outcome of intervention is supporting the client's "health and participation in life through engagement in occupation" (p. 648).⁵ The steps of evaluation, intervention, and outcome should not be viewed in a linear fashion but instead should be seen as a circular or spiraling process where the parts are mutually influential.

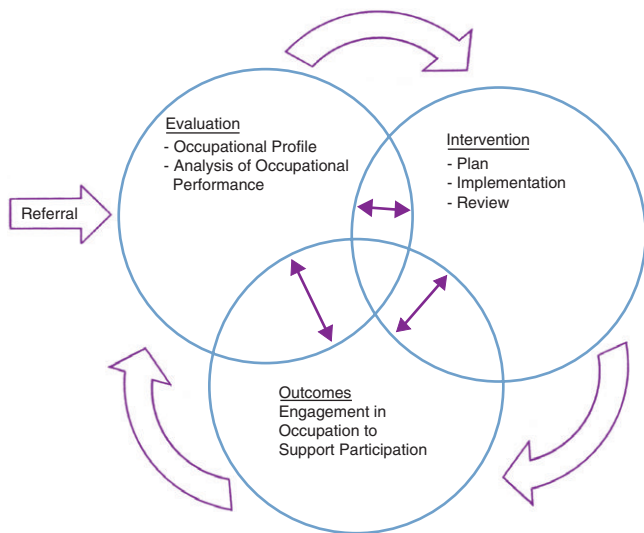

FIGURE 3-1 Intervention process.

Referral

The physician or other legally qualified professional requests occupational therapy services for the client. The referral may be oral, but a written record is often a necessity. Guidelines for referral vary, and in some situations occupational therapy services may require a physician's referral. The occupational therapist (OT) is responsible for responding to the referral. Although clients may seek occupational therapy services without first obtaining a referral, the occupational therapist may need a referral prior to the initiation of intervention services. State regulatory boards and licensing requirements should be reviewed prior to initiation of services to determine if a referral for service is necessary.

Screening

The OT determines whether further evaluation is warranted and if occupational therapy services would be helpful to this client. The therapist may perform a screening independently or as a member of the healthcare team. Screening procedures are generally brief and do not cover all areas of occupation. A formal screen is not always conducted with the client but, during the review of the client's record prior to the evaluation, the OT considers the diagnosis, physical condition, referral, and information from other professionals. The therapist then synthesizes this information prior to initiating an evaluation. In some settings, the screening process flows directly into the evaluation of the client in a seamless manner.

Evaluation

Evaluation refers to “the process of obtaining and interpreting data necessary for intervention. This includes planning for and documenting the evaluation process and results.”¹ Assessment refers “to specific tools or instruments that are used during the evaluation process.”¹ Two parts of the

evaluation process have been identified: the generation of an occupational profile and the analysis of occupational performance. The assessments chosen help in developing the occupational profile. The OT then analyzes the client's occupational performance through synthesis of data collected using a variety of means.

The evaluation portion begins with the OT and client developing an occupational profile that reviews the client's occupational history and describes the client's current needs and priorities.^{5,12} This portion of the evaluation process includes the client's previous roles and the contexts for occupational performance. For example, Sheena has been assigned to develop an occupational profile for a 56-year-old man who recently had a tumor removed from his right cerebral hemisphere, resulting in dense left hemiplegia. He has been married to his wife for 27 years and reports that he never cooks. On further exploration during the development of the occupational profile, the man reports that one of his most treasured occupations is being able to grill and discusses the importance of grilling over charcoal versus using a gas grill. Although Sheena may have initially ignored the need to work on cooking skills with this man, she now understands the occupational significance of grilling and, from the client's perspective, the difference between grilling and cooking! The occupational profile allows the OT to understand the client's occupational history, current needs, and priorities, and identifies which occupations or activities are successfully completed and those that are problematic for the client.

The occupational profile is most often initiated with an interview with the client, and significant others in the client's life, and by a thorough review of available records.⁵ Interviews may be completed using a formal instrument or informal tools. Although the occupational profile is used to focus subsequent intervention, this profile is often revised throughout the course of intervention to meet a client's needs. The purpose of the occupational profile is to answer the following questions as articulated in the American Occupational Therapy Association (AOTA) document:⁵

1. *Who is the client?* This requires consideration of not only the individual but the significant others in the client's life. In some settings the client may be identified as a group and not as an individual. For example, a 28-year-old woman, Nora, who sustained a traumatic brain injury resulting in memory deficits and slight difficulties with coordination, is a wife and a mother to two young children. During the evaluation process, Sheena considers not only Nora's occupational needs but also the needs of her family and her roles as a family member.
2. *Why is the client seeking service?* This relates to the occupational needs identified by the individual and significant others. The needs of not only Nora but those of her husband and children should be included in answering this question.

3. *What occupations and activities are successful or are problematic for the client?* This would also include understanding which occupations are successfully completed by the client. Nora may have the physical ability to drive and yet has severe memory problems and difficulties remembering the route to drive her children to school and various activities.
4. *How do contexts and environments influence engagement in occupations and desired outcomes?* Some contexts may be supportive, whereas others present challenges or prohibit occupational performance. Nora's parents expect her to be the primary caregiver for her children and when her husband attempts to support Nora, her parents interfere.
5. *What is the client's occupational history?* This includes the level of engagement in various occupations and activities along with the value attributed to those occupations by the client. Although prior to her traumatic brain injury Nora was responsible for the majority of the housecleaning tasks, Nora did not highly value these duties. She was also responsible for meal preparation and reports that she enjoys cooking. She places a much higher value on being able to drive her children to school and various after-school activities.
6. *What are the client's priorities and targeted outcomes?* These may be identified as occupational performance, role competence, adaptation to the circumstance, health and wellness, prevention, or quality-of-life issues. For Nora, the need to safely drive and resume responsibility for fostering community participation for her children was a primary outcome. This reflects her interest in occupational performance. She was not interested in having her parents or her husband assume these roles.

After the occupational profile is developed, the OT identifies the necessary additional information to be collected, including areas to be evaluated and what assessment instruments should be used prior to the analysis of occupational performance. The OT may delegate some parts of the evaluation, such as the administration of selected assessment tools, to the occupational therapy assistant (OTA). The interpretation of data is the responsibility of the OT. This requires the OT to direct the evaluation by completing an occupational profile, interpreting the data collected from the profile, and then analyzing the client's occupational performance prior to proceeding to assessment of client factors. The selection of additional information beyond the occupational profile should answer the following questions:

1. What additional data are needed to understand the client's occupational needs including contextual supports and challenges?
2. What is the best (most efficient and accurate) way to collect these data?
3. How will this information support the intervention plan?
4. How will this information influence potential outcomes?

The ability of the client to successfully plan, initiate, and complete various occupations is then evaluated. The occupations chosen are based on the occupational profile. The OT then analyzes the data to determine the client's specific strengths and weaknesses that impact occupational performance. The impact of contextual factors on occupational performance is included in the analysis of data. This can easily be seen when a client who is dependent on a wheelchair for all mobility is faced with several stairs to enter an office building to conduct business. The client has functional mobility skills but is prohibited from participating because of an environmental factor that restricts access. The analysis includes integrating data regarding the activity demands, the client's previous and current occupational patterns, and the client factors that support or prohibit occupational performance. Data about specific client factors may be helpful in developing an intervention plan but should be performed after the occupational profile is completed and an analysis of occupational performance has been initiated. The information generated from the profile and analysis will allow more careful selection of necessary assessment tools to collect further data. The OT also considers if the client would benefit from a referral to other professionals.

Now consider the case presentation from the beginning of the chapter. Although Sheena is able to competently perform a manual muscle test and range-of-motion assessment, these assessments would not be necessary for all clients. Sheena must first develop the client's occupational profile as a guide to then select the most appropriate assessment instruments to complete her evaluation of the client's occupational performance. After she has completed these steps, Sheena is able to more clearly identify what additional information is needed to plan and implement intervention services.

Intervention Planning

Working with the client, the occupational therapy practitioners (OT and OTA) develop a plan using the following approaches or strategies to enhance the client's ability to participate in occupational performance.^{5,12} Although the OT is responsible for the plan, the OTA contributes to the plan and must be "knowledgeable about the evaluation results" (p. 665).³ The strategies selected should be linked to the intended outcomes of service.⁵ These approaches or strategies answer the question, "What type (approach/strategy) of intervention will be provided to meet the client's goals?" Examples of each form of intervention approach or

strategy are provided with selected literature to support this form of occupational therapy intervention:

1. *Prevention of disability.* This approach is focused on developing the performance skills and patterns that support continued occupational performance and provides intervention that anticipates potential hazards or challenges to occupational performance. Contextual issues are also addressed using this approach and environmental barriers would be similarly considered. An example of services representing a preventative approach would be instructing a client who has compromised standing balance in fall prevention techniques and asking the family to remove loose throw rugs from the home to avoid falls.²⁴ Clark et al.²¹ demonstrated the beneficial effects of preventative occupational therapy services in the investigation of well, elderly adults. Adults who received preventative occupational therapy displayed far fewer health and functional problems when compared to adults who did not receive these services.
2. *Health promotion.* A disabling condition is not assumed, but instead occupational therapy services are provided to enhance and enrich occupational pursuits. This approach may be used to help clients who are transitioning in roles or used to foster occupational performance across contexts. An example would be using narratives to promote a healthy transition from the role of a worker to retirement.⁴² As workers described what they anticipated in retirement, they linked “past, present, and future” (p. 49). This process of anticipating changes and making choices was considered to be an important factor in “understanding how people adapt to life changes” (p. 49).
3. *Establish or restore a skill or ability.* This strategy is aimed at improving a client’s skills or abilities, thus allowing greater participation in occupations. Evidence of the effectiveness of occupational therapy services provides this form of intervention as demonstrated by several investigators. Walker et al.⁸⁰ investigated the effectiveness of occupational therapy services in restoring activities of daily living (ADL) and instrumental activities of daily living (IADL) skills in clients who had sustained a cerebrovascular accident (CVA) but had not received inpatient rehabilitation services. They used a randomized controlled trial and demonstrated that clients receiving occupational therapy services had significantly better ADL and IADL performance when compared to clients who had not received these services. Rogers et al.⁶⁹ also demonstrated that performance of ADLs can be significantly improved when provided with systematic training.
4. *Adapt or compensate.* This approach is focused on modifying the environment, the activity demands, or

the client’s performance patterns to support health and participation in occupations. Instruction and use of energy conservation techniques for clients who have dyspnea (shortness of breath or difficulty breathing) as a result of chronic obstructive pulmonary disease is an example of this approach.⁵⁵ The use of electronic aids to daily living (EADL) is another example of how the activity can be modified to promote participation.²⁹ When clients who had acquired brain damage were provided with training in the use of EADL, they reported a sense of mastery. Even if a client’s previous abilities cannot be restored, employing this adaptive or compensatory approach can promote participation in occupations.

5. *Maintain current functional abilities.* This approach recognizes that many clients are faced with degenerative disorders, and occupational therapy services should actively address the need to maintain occupational engagement.^{19,31} Intervention may focus on the activity demands, performance patterns, or context for occupational performance. As an example, an individual in the early stage of Parkinson’s disease is still able to complete many self-care activities but should develop the habits that will maintain these skills as motor function continues to deteriorate. Maintenance also includes clients who have a chronic, nonprogressive disorder; in this situation there is a need for maintaining physical conditioning to meet activity and environmental demands.

Through collaboration with the client and significant others, the intervention plan identifies not only the specific focus of the goal but also the explicit content of the goal. For example, Nora, who sustained a traumatic brain injury, indicated that she wanted to be able to return to driving her children to various community-based activities. Services would focus on two approaches: restoring the skills needed to engage in this occupation of driving her children to community activities and adapting the performance by avoiding community activities that necessitate driving during heavy traffic periods in the morning and late afternoon.

Specific driving skills would be improved using strategies to enhance reaction time, problem solving, and attention to potential safety risks. Because of Nora’s diminished memory and difficulties with processing complex information, the occupation of driving her children to community activities should be modified. Nora could select community activities that are close to her children’s school and home, thereby decreasing the length of time she is driving her children. Through the use of a programmable guidance system in her car, such as a global positioning system (GPS), she is able to follow the specific directions to the various community activities. If these intervention approaches are unsuccessful, the OT may explore alternatives to driving with Nora, such as bicycling or walking with her children to nearby community activities or carpooling with another

■ **TABLE 3-1** | **Format for Writing Goals**

A. Actor	Begin the goal with a statement such as “Nora will ...” Name the client as the performer of the action for the goal.
B. Behavior	The occupation, activity, task, or skill to be performed by the client. If this is an outcome or terminal goal, the behavior must reflect occupational performance. Short-term goals or behavioral objectives are often steps to reaching a long-term goal or outcome. A short-term goal or objective may identify a client factor or performance skill as the targeted behavior. An outcome behavior for Nora would be the ability to drive a car, whereas a short-term behavior would be to enter the car and fasten a seatbelt.
C. Condition	The situations for the performance of the stated behavior include social and physical environmental situations for the behavior. Examples of conditions included in a goal are the equipment used, social setting, and training necessary for the stated behavior. In the situation of Nora, driving a car with an automatic transmission is a far different condition than driving a car with a manual transmission.
D. Degree	The measure applied to the behavior and the criteria for how well the behavior is performed. These may include repetitions, duration, or the amount of the activity completed. A client may only be expected to complete a small portion of an activity as a short-term goal, but the long-term goal would address the targeted occupation. The amount of support provided serves as a measure of degree of behavioral performance. This would include whether the client required minimal assistance, verbal prompts, or performed the task independently. The criteria must be appropriate for the behavior. Safely driving 50% of the time is an inappropriate criterion, but using a percentage to indicate that Nora will independently fasten her seat belt 100% of the time provides an appropriate criterion for the behavior
E: Expected time frame	When is the goal to be met, the time period that is anticipated to meet the goal as stated.

Adapted from Kettenbach G: *Writing SOAP notes*, ed 3, Philadelphia, 2004, FA Davis.

parent where the other parent assumes the actual driving role and Nora contributes by providing snacks or gas money. Such alternatives could provide a safer solution and still meet the need for Nora to be involved in the occupation of driving or transporting her children to their community activities.

The OT is responsible for the plan and for any parts delegated to the OTA. The plan includes client-centered goals and methods for reaching them using the above-mentioned approaches or strategies. The values and goals of the client are primary; those of the therapist are secondary.⁵ Cultural, social, and environmental factors are incorporated into the plan. The plan must identify the scope and frequency of the intervention and the anticipated date of completion. The outcomes of the intervention must be written at the time the intervention plan is developed. Discharge planning is initiated during the intervention planning process. This is accomplished by developing clear outcomes and targeted time frames for the completion of goals.

The generation of clear and measurable goals is a very important step in the planning process. Long-term goals or terminal behaviors must reflect a change in occupational performance. For a client to receive authentic occupational therapy services, there must be a focus on “supporting health and participation in life through engagement in occupation” (p. 626).⁵ This may be achieved through several

means, including improved occupational performance, role competence, adaptation, prevention, or quality of life. To meet this outcome, short-term goals or behavioral objectives reflect the incremental steps that must occur to reach this target. An example would be Nora returning to driving. Several short-term steps would be necessary prior to meeting this terminal behavior or long-term goal. An intervention plan may address bilateral coordination and speed of reaction prior to having Nora return to driving. Several authors have provided detailed descriptions of the critical parts of a well-written goal.⁴³ Table 3-1 serves as a brief guide for the development of goals and objectives. (For additional details regarding goals and documentation, see Chapter 8.)

Intervention Implementation

The intervention plan is implemented by the OT practitioners. The OT may assign to the OTA specific responsibilities in delivery of the intervention plan. Nonetheless, the OT retains the responsibility to direct, monitor, and supervise the intervention and must ensure that relevant and necessary interventions are provided in an appropriate and safe manner and that documentation is accurate and complete.³ The method used to provide interventions could include therapeutic use of self, therapeutic use of occupations and activities, consultation, education, or advocacy.⁵ (See Chapter 1 for a more detailed description of these methods of providing intervention.) These methods answer

the question, “How will intervention strategies be provided?” The intervention plan would identify which approach or strategy would be used in combination with the method of intervention. During the actual implementation of intervention services, a clinician may seamlessly shift between different methods, depending on the needs of the client.

OT Practice Notes

The implementation of the intervention plan does not occur in isolation but requires the clinician to continuously review the effectiveness of the services delivered by monitoring the client’s response to intervention. At the beginning of each intervention session, the OT should answer the following questions:

1. What is the primary focus of intervention for this session?
2. How will this service meet the client’s goals and needs?

Implementation of services should also include helping the client anticipate needs and solutions. A method developed by Schultz-Krohn⁷⁴ provides a structure to this process and was labeled anticipatory problem solving. This process was developed from client-centered models such as the model of human occupation⁴⁴ and the person-environment-occupation^{48,49} model described later in this chapter. This process was designed to empower the client to anticipate potential challenges and develop solutions prior to encountering the challenges. The key elements of the anticipatory problem-solving process are as follows:

1. The client and clinician identify the occupation or activity to be performed.
2. The specific features of the environment that are required for occupational/activity performance are identified. This includes contextual and environmental factors in addition to the necessary equipment to engage in the occupation/activity.
3. The OT and client identify potential safety risks or challenges to engagement in the occupation/activity that are located in the environment or with the objects required.
4. The OT and client develop a solution for these risks or challenges.

An example would be Nora, who would like to be able to drive her children to after-school activities. As she regains her abilities to drive, anticipatory problem-solving strategies are employed to prepare her for potential environmental challenges. The process follows these steps:

1. Nora and the OT identified the occupation of driving her children to after-school music lessons as the focus for intervention.

2. The car has an automatic transmission. The route typically used to drive her children from school to the lessons includes a busy street with four lanes, but no highway driving is required. She does need to make one left-hand turn on this street, but there is a left turn light. The travel time typically takes 10 minutes.
3. Nora reports that traveling on the one busy street can be a challenge because many drivers exceed the speed limit on this road and drive erratically. This is the quickest route to the music lessons and because she is very familiar with the route, it provides less challenge to her memory. Nora’s husband also reports that this road often has construction, presenting an additional challenge.
4. Instead of changing the route, Nora develops a solution whereby she allocates an additional 5 minutes to transport her children to lessons, allowing her to feel less pressure when drivers are exceeding the speed limit. Strategies to address the erratic drivers encountered on this road included frequent checks of her side mirrors and moving to the left lane two intersections before the left-hand turn light. An alternate route is also mapped out for Nora to use when road construction presents a challenge.

This process provides a brief illustration of how anticipatory problem-solving methods can be used during the intervention implementation. This process can be equally applied to bathing, where a client anticipates the potential hazard of a slippery surface and makes appropriate plans before bathing. The foundation of this process is to engage the client in developing solutions for everyday challenges encountered as he or she engages in occupations/activities. The client is actively involved in identifying not only the occupation/activity but also potential challenges or risks encountered and generating solutions for the identified challenges or risks.

Included in the intervention implementation process is the ongoing monitoring of the client’s response to the services provided. As services are initiated, the OT monitors the client’s progression on a continuous basis and modifies the intervention methods used as needed to support the client’s health and participation in life.

Intervention Review

The occupational therapy practitioners evaluate the intervention plan on a regular basis to determine if the client’s goals are being met.⁵ The OT is “responsible for determining the need for continuing, modifying, or discontinuing occupational therapy services” (p. 665), but the OTA contributes to this process.³ The review may include a reevaluation of the client’s status to determine what changes have occurred since the previous evaluation. This measurement of the outcomes of intervention is critical in showing the effectiveness of the intervention. The intervention plan may

be changed, continued, or discontinued, based on the results of the reevaluation. This reevaluation also offers an opportunity to determine if the intervention provided is focused on the outcomes articulated in the plan.

Outcomes

Working in collaboration with the client, the client's family, and the intervention team, the OT and OTA identify the intended outcome of the intervention. Although the OTPF-2 clearly states that the outcome of occupational therapy services is focused on "supporting health and participation in life through engagement in occupation"⁵ (p. 660), this outcome can be measured in several ways. Outcomes may be written to reflect a client's improved occupational performance; a change in the client's response to an occupational challenge; effective role performance; habits and routines that foster health, wellness, or the prevention or lessening of further disability; and client satisfaction in the services provided. Client satisfaction can also include overall quality of life outcomes that often incorporate several of the previously mentioned outcomes.

Although the overarching outcome of occupational therapy intervention is "supporting health and participation in life through engagement in occupation" (p. 626), this goal can be achieved through several types of outcomes.⁵ The decision of whether the selected outcomes are successfully met is made collaboratively with the members of the intervention team including the client. The outcomes may require periodic revisions because of changes in the client's status. When the client has reached the established goals or achieved the maximum benefit from occupational therapy services, the OT formally discontinues service and creates a discontinuation plan that documents follow-up recommendations and arrangements. Final documentation includes a record of any change in the client's status from first evaluation through the end of services.

Figure 3-1 shows the relationship between the various parts of the intervention process. This process is not completed in a linear fashion but instead requires constant monitoring, and each section informs the other parts of the process. The outcome generated during the planning step should direct an OT to select intervention methods best suited to reach the desired client goals. During the intervention process, it may become apparent that the desired outcome is not realistic, necessitating revision of the client's goals and outcome of services.

Clinical Reasoning in the Intervention Process

Since 1986, the American Occupational Therapy Association (AOTA) has funded a series of investigations to examine how occupational therapists think and reason in their work with clients.³⁵ Clinical reasoning can be defined informally

as the process used by OT practitioners to understand the client's occupational needs, make decisions about intervention services, and as a means to think about what we do. There are several forms of clinical reasoning, and authors do not consistently use the same term for specific forms of clinical reasoning. Fleming³³ identified three "tracks" of clinical reasoning used by the expert clinician to organize and process data: procedural, interactive, and conditional. Yet another dimension of clinical reasoning, identified as narrative reasoning, has been discussed in the literature by Mattingly.⁵³ The fifth form of clinical reasoning, pragmatic reasoning, describes the practical issues and contextual factors that must be addressed.^{57,72} This section will describe how the five basic forms of clinical reasoning, discussed in current literature, can be applied to practice.

Procedural reasoning is concerned with getting things done, with what "has to happen next." This reasoning process is closely related to the medical form of problem solving. The emphasis is often placed on client factors and body functions and structures when this form of reasoning is employed. A connection between the problems identified and the interventions provided is sought using this form of reasoning and can be seen in critical pathways developed in some hospitals. A critical pathway is a form of a decision-making tree based on a series of yes/no questions that can direct client intervention. For example, a client who had a total hip replacement would receive intervention that follows a predicted or anticipated trajectory of recovery. Critical pathways are often developed to support best practice when there is substantial information about a client's course of recovery from a surgical procedure or medical treatment. Procedural reasoning would be used to develop critical pathways and is driven by the client's diagnosis and potential outcomes anticipated for individuals with this diagnosis. This form of clinical reasoning is influenced by using current evidence about the client's condition and selected intervention.⁵¹ An OT should review literature on an ongoing basis to provide effective and appropriate intervention services.⁵⁴ Using this knowledge to develop and implement intervention reflects procedural reasoning in practice.

Interactive reasoning is concerned with the interchanges between the client and therapist. The therapist uses this form of reasoning to engage with, to understand, and to motivate the client. Understanding the disability from the client's point of view is fundamental to this type of reasoning. This form of reasoning is used during the evaluation to detect the important information provided by the client and to further explore the client's occupational needs. During intervention, this form of reasoning is used to assess the effectiveness of the intervention selected in meeting the client's goals. The therapeutic use of self fits well with this form of clinical reasoning as a therapist employs personal skills and attributes to engage the client in the intervention process.

Conditional reasoning is concerned with the contexts in which interventions occur, the contexts in which the client performs occupations, and the ways in which various factors might affect the outcomes and direction of therapy. Using a “what if?” or conditional approach, the therapist imagines possible scenarios for the client. The therapist engages in conditional reasoning to integrate the client’s current status with the hoped-for future. Intervention is often revised on a moment-to-moment basis to proceed to an outcome that will allow the client to participate in various contexts. Although an intervention is designed and implemented to foster occupational pursuits, conditional reasoning is not singularly focused on reaching the outcome. Conditional reasoning recognizes that the process of intervention often necessitates a reappraisal of outcomes. This reappraisal should be encouraged to help the client refine goals and outcomes.

Narrative reasoning uses story making or storytelling as a way to understand the client’s experience. The client’s explanation or description of life and the disability experience reveal themes that permeate the client’s understanding and that will affect the enactment and outcomes of therapeutic intervention. In this sense, narrative reasoning is phenomenological. Therapists also use narrative reasoning to plan the intervention session, to create a story line of what will happen for the client as a result of therapy. Here the therapist draws on both interactive and conditional reasoning using the client’s words and metaphors to project possible futures for the client. The therapeutic use of self is critical when employing this form of clinical reasoning. Providing an opportunity for the client to share the meaning of the disability experience helps with formulating plans and projecting future occupational performance. This is where the context and occupational performance intersects. A person may be able to engage in an activity with modifications, but those modifications may be unacceptable within the client’s cultural and social context. For example, an individual who, prior to a stroke, was an avid motorcyclist is now unable to control the clutch and hand controls necessary to safely drive a motorcycle and also has impaired balance. Although automatic motorcycles are now available with three wheels, this client refuses the option, considering this to be not part of the motorcycle culture.

Pragmatic reasoning extends beyond the interaction of the client and therapist. This form of reasoning integrates several variables including the demands of the intervention setting, the therapist’s competence, the client’s social and financial resources, and the client’s potential discharge environment. Pragmatic reasoning recognizes the constraints faced by the practicing therapist by forces beyond the client-therapist relationship. For example, a hospital that provides inpatient services may not have the resources for a therapist to make a home visit prior to a client being discharged. A therapist working solely through a home health agency will not have full access to clinic equipment when working in

the client’s home. These challenges to providing intervention would be considered when developing an intervention plan using pragmatic reasoning.

Experienced master clinicians engage in all forms of reasoning to develop and modify their plans and actions during all phases of the occupational therapy process. Some of the questions a therapist might consider related to each form of clinical reasoning are listed in [Box 3-1](#).

■ Box 3-1

Questions to Engage in Clinical Reasoning

Procedural Questions

- What is the diagnosis?
- What prognosis, complications, and other factors are associated with this diagnosis?
- What is the general protocol for assessment and intervention with this diagnosis?
- What interventions (adjunctive methods, enabling activities, purposeful activities) might be employed?
- What evidence supports the use of specific interventions to foster occupational performance?

Interactive Questions

- Who is the client?
- What are the client’s goals, concerns, interests, and values?
- How does the client view his or her occupational performance status?
- How does the illness or disability fit into the client’s performance patterns?
- How might I engage this client?
- How can we communicate?

Conditional Questions

- What contexts has the client identified as important in his or her life?
- What future(s) can be imagined for the client?
- What events could or would shape the future?
- How can I engage the client to imagine, believe in, and work toward a future?

Narrative Reasoning

- What does the change in occupational performance mean to this client?
- How is this change positioned within the client’s life history?
- How does the client experience the disabling condition?
- What vision does the therapist hold for the client in the future?
- What “unfolding story” will bring this vision to fruition?

Pragmatic Reasoning

- What organizational supports and constraints must be incorporated into the provision of services?
- What physical environmental factors must be considered when designing an intervention plan?
- What is the therapist’s knowledge and skill level?

Clinical Reasoning in Context

Pressures for cost containment and reduction of unnecessary services require therapists to balance the needs of the client and the practical realities of healthcare reimbursement and documentation. Thus, on first meeting the client, the therapist will want to know the anticipated or required date of discharge, as well as the scope of services that will be reimbursed and those that are likely to be denied. Simultaneously, the therapist is formulating an occupational profile with the client, evaluating the client's occupational performance, engaging the client in identifying outcomes and goals, and determining which interventions would best meet the desired outcomes. The OT also considers the contextual factors that will influence occupational performance. Further, the therapist is alert to requirements for documentation and the particular current procedural terminology (CPT) codes that may apply. The OT must document service accurately and effectively so that reimbursement will not be challenged and the client's needs may be adequately addressed. (For a more detailed discussion of documentation, see Chapter 8.)

From first meeting the client, the therapist is guided by the client's goals and preferences. Client-centered service delivery requires client (or family) involvement and collaboration at all stages of the intervention process.⁵ To effectively engage the client and the family demands, cultural sensitivity and an ability to communicate with people of diverse backgrounds is required.^{17,76,79,81} In some cultures, the idea of participating equally in decision making with a health professional may be unknown. Being asked by a therapist to make decisions may feel quite unfamiliar and uncomfortable to the client. Thus, the therapist must support the client's ability to collaborate, adjust to the client's point of view, and find other ways to ensure that the intervention plan, including intended outcomes, is acceptable to the client and significant others in the client's life. Understanding the influence of culture on the client's occupational performance and performance patterns is fundamental to the provision of services.¹⁷ The OT should pose the following questions to foster cultural competence in the provision of services:

1. *What do I know about the client's culture and beliefs about health?* This represents the basic knowledge of cultural health practices and beliefs. Conclusions or judgments should not be formed about why these practices are present.
2. *Does the client agree with these beliefs?* Although a client may affiliate with a specific cultural group, the OT must investigate to determine if the cultural beliefs of health and the client's beliefs of health are similar.
3. *How will these beliefs influence the intervention and outcomes of services provided?* The OT must

acknowledge and respond to the influences of cultural beliefs and practices within the intervention plan. To design a plan that conflicts with cultural beliefs would not only be counterproductive to client-centered services but would be disrespectful of the client's belief system. If a client, in deference to the authority of the OT, follows an intervention that conflicts with cultural practices, the client may risk receiving support and affiliation with that cultural group.

4. *How can the intervention plan support culturally endorsed occupations, roles, and responsibilities to promote the client's engagement in occupation?* The OT must consider the important occupations from a cultural perspective. Evening meals may include specific behaviors that possess strong cultural symbols for one client, but another client may view an evening meal as merely taking in food with no prescribed rituals.

Client-Centered Practice

Involving clients in identifying their own goals and in making decisions about their own care and intervention is highly valued by leaders in the OT profession^{32,63,73} and is endorsed by the AOTA in its policy and practice guidelines.⁷ Client-centered practice begins when the therapist first meets the client. Therapists using an occupation-based assessment tool, such as the Canadian Occupational Performance Measure (COPM),⁴⁷ initiate assessment by asking clients to identify and choose goals early in the evaluation process. This process can be fostered when the therapist is aware of potential biases that could influence the development of goals.⁷¹ Regardless of disability status or perceived limitations in cognitive functioning, every client should be invited to participate in evaluation and intervention decisions. Client-centered practice is guided by the following concepts:⁹

- The language used reflects the client as a person first and the condition second.
- The client is offered choices and is supported in directing the occupational therapy process. This requires the occupational therapist to provide information about the client's condition and the evidence available regarding the various types of intervention.
- Intervention is provided in a flexible and accessible manner to meet the client's needs.
- Intervention is contextually appropriate and relevant.
- There is clear respect for differences and diversity in the occupational therapy process.

Although client-centered practice is most often conceptualized as the OT practitioner working with a person and those significant in that person's life, the OTPF-2 describes "clients" as persons, organizations, and/or populations. When providing OT services to organizations or

populations, the OT practitioner is still expected to apply the same values of client-centered practice and enlist the client, whether an organization or population, in identifying goals and selecting outcomes.

Theories, Models of Practice, and Frames of Reference

The profession of occupational therapy acknowledges the need for theories, models of practice, and frames of reference to advance the profession, demonstrate evidence-based intervention, and more clearly view occupation.⁴⁴ Theories, models of practice, and frames of reference offer the clinician a means to understand and interpret information to develop an effective intervention plan. These terms require definition and understanding prior to application to practice.

Theory

This term refers to the process of understanding phenomena including articulating concepts that describe and define phenomena and the relationships between observed events across situations or settings. A theory is tested across settings for confirmation of concepts and relationships. Although a theory may be generated from one profession, it is often applied across professions when the theory is an accepted method of understanding phenomena. According to Reed,⁶⁶ theory attempts to do the following:

- Define and explain relationships between concepts or ideas related to the phenomenon of interest (for example, occupational performance and occupation).
- Explain how these relationships can predict behavior or events.
- Suggest ways that the phenomenon can be changed or controlled.”

A clear example of a theory that meets these expectations and is well known is germ theory.¹⁵ Widely accepted and tested, germ theory states that microorganisms produce infections. Prior to understanding the relationship between these microorganisms and infections, physicians would perform an autopsy and then go to an adjacent room to deliver a baby without washing hands between the two events. The number and severity of infections occurring after childbirth dramatically decreased when germ theory was accepted and then functionally applied to practice (a frame of reference) through the use of proper hand-washing procedures. From an occupational therapy perspective, theories provide the profession with a means to examine occupation and occupational performance and understand the relationship between engagement in occupations and participation in context.⁴⁴ The main purpose of a theory is to understand the specific phenomenon. Mary Reilly's theory of occupational behavior was designed to explain the importance of occupation and the relationship between

occupation and health.^{67,68} Her theory served as a foundation for several models of practice within the profession of occupational therapy.

Model of Practice

Model of practice refers to the application of theory to occupational therapy practice. This process is achieved through several means such as the development of specific assessments and articulation of principles to guide intervention. Models of practice are not intervention protocols but instead serve as a means to view occupation through the lens of theory with the focus on the client's occupational performance. Models of practice often serve as a mechanism to engage in further testing of the theory.⁴⁴ Some authors refer to models of practice as conceptual models,¹⁸ whereas other authors include models of practice in the discussion of professional theories.²³ In the profession of occupational therapy, several models of practice exist, but the commonality seen in each is the focus on occupation. The main purpose of a model of practice is to facilitate the analysis of the occupational profile and consider potential outcomes with selected interventions. Models should be applicable across settings and client groups instead of designed primarily for a specific diagnostic group. From a very colloquial expression, a model of practice is where the clinician “puts on the OT eyeglasses” to bring into focus the client's needs and abilities, various contextual issues, and engagement in occupation. Three of these models of practice will be briefly described. The reader is encouraged to seek additional information from the materials used in this brief description.

Model of Human Occupation

In the model of human occupation (MOHO),⁴⁴ the engagement in occupation is understood as the product of three interrelated subsystems that cannot be reduced to a linear process. These three subsystems are linked to produce occupational performance. The volitional subsystem refers to the client's values, interests, and personal causation. A client may clearly identify values and interests to a clinician but then express a sense of incompetence to engage in a desired occupation. Volition is the client's thoughts and feelings, including occupational choices. The habituation subsystem refers to the habits and roles that are often critical to a sense of self. Colloquial phrases such as “I don't feel like myself” expressed by a client often speak of a distortion of habit or role experienced in life. A client, faced with a disabling condition, often experiences a severe disruption in roles and habits. The sense of self can deteriorate when roles such as driving to work, driving to go shopping, or driving friends to enjoy a picnic are eliminated because of a disabling condition. The performance capacity subsystem reflects the client's lived experience of the body. This is not the strength or range of motion available but refers to the client's previous experience, changes, and expectations of performance capacity. Again, using the colloquial phrase “once you've

ridden a bicycle, you never forget” captures a portion of this concept and requires the therapist to consider the client’s experience of successes or failures in using the body to engage in occupations.

Ecology of Human Performance

Ecology of human performance (EHP)²⁷ was not designed to be used exclusively within the profession of occupational therapy but was intended to serve as a mechanism for understanding human performance across professions. An important concept expressed in the EHP is the interaction of the person, the task (activity demands), and the context. Occupational performance is intertwined with, and the product of, the interaction of these three variables. EHP is a client-centered model in which each person is viewed as unique and complex and includes past experiences, skills, needs, and attributes. The task is understood as the objective and observable behaviors to accomplish a goal. The context includes the person’s age, life cycle, and health status from a perspective of the cultural and societal meanings of each. Context also addresses the physical, social, and cultural factors that influence performance. EHP recognizes that these three factors influence each other and that the person and task are inextricably linked with the context. Performance is the product of the person engaged in a task within a context. A significant contribution of this model is the equal importance placed on each variable in producing occupational performance. Instead of focusing only on improving skills in the person, intervention using this model can assume several forms. Five intervention strategies are described, and a close similarity to the OTPF-2 can be seen. The five strategies include the following:²⁸

1. *Establish/restore.* Although focused on improving the person’s abilities and skills, the intervention includes the context for performance.
2. *Alter.* Intervention is designed to alter the contextual factors to foster occupational performance; an example would be home modifications to allow wheelchair access.
3. *Adapt/modify.* The task or context is adapted or modified to support performance such as use of a reacher to obtain objects or using elastic shoelaces to eliminate the need to tie shoes.
4. *Prevent.* Intervention may address the person, the context, or the task to prevent potential problems from occurring; examples would be teaching the client back-safety techniques to prevent back injuries, removing rugs in an environment to reduce the risk of falls as a contextual prevention method, and turning down the water temperature for a client with sensory problems to reduce the risk of burns when bathing.
5. *Create.* Intervention addresses all three variables of the person, task, and context and is designed to

develop or create opportunities for occupational performance.

Person-Environment-Occupation Model

The person-environment-occupation model (PEO)^{48,49} shares characteristics with EHP where occupational performance is seen at the intersection of the person, environment, and occupation. It is a client-centered approach, but equal emphasis is placed on the environment and the occupation when designing intervention. PEO defines the person as a dynamic and changing being with skills and abilities to meet roles over the course of time. The environment includes the physical, social, cultural, and institutional factors that influence occupational performance. Occupations include self-care and productive and leisure pursuits. PEO further differentiates the progression from an activity, a small portion of a task, a task that is a clear step toward an occupation, and the occupation itself, which often evolves over time. An example would be the activity of safely handling a knife. This is a small portion of the task of making a peanut butter and jelly sandwich, and the task of making a sandwich is seen as a part of the occupation of meal preparation. Occupational performance is the result of the person, environment, and occupation interacting in a dynamic manner.

Frame of Reference

The purpose of a frame of reference (FOR) is to help the clinician link theory to intervention strategies and to apply clinical reasoning to the chosen intervention methods.^{45,56} A FOR tends to have a more narrow view of how to approach occupational performance when compared to models of practice. The intervention strategies described within various FORs are not meant to be used as a protocol but offer the practitioner a way to structure intervention and think about intervention progressions. The clinician must always engage in the various forms of clinical reasoning to question the efficacy of the intervention in meeting the client’s goals and outcomes.

A frame of reference should be well fitted to meet the client’s goals and hoped-for outcomes. The colloquial concept of “one size fits all” definitely does not apply to the use of a FOR to guide intervention. That is why there is a need for multiple FORs to meet varied client goals and outcomes. A clinician may blend intervention strategies from several FORs to effectively meet the client’s needs. As an example, a client may be able to recover precise coordination and control of both arms following a traumatic brain injury (TBI) if the OT practitioner combines a biomechanical and a sensorimotor FOR, but the client may have persistent memory deficits requiring the use strategies following a rehabilitative FOR. The following brief descriptions are not meant to be an exhaustive review of all possible FORs that can be used in occupational therapy. Examples are provided to illustrate how a FOR can be used to guide the intervention process.

Biomechanical

The understanding of kinematics and kinesiology serves as the foundation for the biomechanical FOR.⁷⁵ The clinician views the limitations in occupational performance from a biomechanical perspective, analyzing the movement required to engage in the occupation. Based on principles of physics, the force, leverage, and torque required to perform a task or activity are assessed. These also serve as the basis for intervention. A client may be unable to open a jar of peanut butter or jelly because of limitations in grip strength or the available range of motion required of the hands to hold the jar. A biomechanical approach would focus intervention on addressing these basic client factors to improve occupational performance. Although intervention may take the form of exercises, splinting, or other orthopedic approaches, the outcome must reflect engagement in occupation.⁴¹

Rehabilitation

The rehabilitation FOR focuses on the client's ability to return to the fullest physical, mental, social, vocational, and economic functioning as is possible. The emphasis is placed on the client's abilities and using the current abilities coupled with technology or equipment to accomplish occupational performance. Compensatory intervention strategies are often employed, and examples include teaching one-handed dressing techniques to an individual who, following a CVA, no longer has functional use of one hand. The focus of intervention is often engagement in occupation through alternative means. (For additional examples of intervention strategies supported by the rehabilitation FOR, see Chapters 10, 11, and 17.) Returning to the same example of making a peanut butter and jelly sandwich, instead of having the client work on strengthening the hands to finally open the jar, the clinician would suggest using a device to stabilize the jar and use a gripper to help accomplish the task with current abilities. Regardless of the technology or equipment available, the clinician must always link the intervention to the client's occupational performance.

Sensorimotor

Several FORs are included in this grouping, such as proprioceptive neuromuscular facilitation (PNF) and neurodevelopmental treatment (NDT) (see Chapter 31 for additional information). These approaches share a common foundation of viewing a client who has sustained a central nervous system insult to the upper motor neurons as having poorly regulated control of the lower motor neurons. To recapture the control of the lower motor neurons, various techniques are employed to promote reorganization of the sensory and motor cortices of the brain. The specific techniques vary but the basic premise is that when the client receives systematic sensory information, his or her brain will reorganize and the return of motor function will be obtained.

Meeting the Client's Needs

The OT relies on theories, models of practice, and FORs to interpret and integrate evaluation data to meet the client's identified outcomes. These are used in conjunction with clinical reasoning to develop an intervention plan and critically review the successfulness of the plan. For example, the OT would use procedural reasoning to select a theory, model, or FOR that has proven successful with clients who have a similar diagnosis. Interactive reasoning is used to assess if the chosen model or FOR is meeting the client's needs. As a therapist applies theories, models, or FORs to meet the client's needs, a series of professional questions should be posed:

1. Does the theory, model of practice, or frame of reference help with understanding and interpreting the evaluation data while considering the client's expressed needs?
2. Does the theory, model of practice, or frame of reference provide a good fit for the type of intervention that will meet the client's needs?
3. What evidence is available that the theory, model of practice, or frame of reference can efficiently produce the results requested by the client?

The preceding questions should be posed throughout the intervention process as a review of the effectiveness of services provided. Although the OT is responsible for interpreting and integrating evaluation data, collaborating with the client to develop the intervention plan, and engaging in ongoing review of the effectiveness of intervention, the OTA contributes to the evaluation and intervention process.

Teamwork within the Occupational Therapy Profession

The OT profession recognizes and certifies two levels of practitioners, the OT and the OTA. The AOTA has provided many documents to guide practice and to clarify the relationship between the two levels of practitioner.^{3,7} The OT operates as an autonomous practitioner with the ability to provide occupational therapy services independently, whereas the OTA "must receive supervision from an occupational therapist to deliver occupational therapy services" (p. 663).³ Even though OTs are considered able to independently provide occupational therapy services, they should seek supervision and mentoring to foster professional growth. The OT who is managing a case or providing services to clients should use the following as a guide:

- Services are to be provided by personnel who have demonstrated service competency. Some states require advanced training and proficiency in specified arenas of practice. For example, an advanced certification in dysphagia (difficulty swallowing) and physical agent

modalities is required in the state of California for an OT to provide those services.

- In the interests of rendering the best care at the least cost, the OT may delegate tasks to OTAs and, in some specific instances, to aides or other personnel, provided these providers have the competencies to render such services. This requires the OT to establish the level of competence required and assess the ability of the OTA, aides, or other personnel to perform those duties.
- The OT retains final responsibility for all aspects of care, including documentation.

OT-OTA Relationships

To work effectively with OTAs, the OT must understand the role of the practitioner trained at the technical level.³ It is common for OTs to alternately overestimate and underestimate the capabilities of OTAs. In overestimating the training and abilities of OTAs, OTs might assume that the OTA is trained to provide services identical to those of the OT but perhaps at a lesser pace and level and with a smaller caseload. In underestimating the OTA, the OT might assume that the OTA is capable of performing only concrete and repetitive tasks under the strictest supervision.

The appropriate role of the OTA is complementary to that of the OT. Employed effectively, the OTA can provide occupational therapy services under supervision that ranges from close to general. AOTA has identified critical factors to consider in the delegation of delivery of occupational therapy services.³ These factors include the severity and complexity of the client's condition and needs, the competency of the OT practitioner, the type of intervention selected to meet the identified outcomes, and the requirements of the practice setting. Working together with several OTAs, the OT will be able to manage a larger caseload and will have the option of introducing more advanced and specialized services, as the role of the OTAs is often to provide routine services. Many variations in the use of OTAs exist across settings. Some services the supervising OT may delegate to the service-competent OTA include the following:

1. Administering selected screening instruments or assessments such as range of motion (ROM) tests, interviews and questionnaires, ADL evaluations, and other assessments that follow a defined protocol.⁷
2. Collaborating with the OT and client to develop portions of the intervention plan (e.g., planning for dressing training and planning for kitchen safety training).⁷
3. Implementing interventions supervised by the OT in the areas of ADL, work, leisure, and play. With appropriate training and supervision, the OTA can implement interventions related to other areas of occupational performance.⁷ As determined by the OT, an OTA can also implement interventions where

competence has been demonstrated. An example would be intervention related to the client factors of strength or range of motion.

4. As assigned by the OT, assisting with the transition to the next service setting by, for example, making arrangements with or educating family members or contacting community providers to address the client needs.
5. Contributing to documentation, record keeping, resource management, quality assurance, selection and procurement of supplies and equipment, and other aspects of service management.
6. Under the supervision of the OT, educating the client, family, or community about OT services.

Occupational Therapy Aides

The OT may also extend the reach of services by employing aides.⁶ AOTA guidelines stipulate that the occupational therapy aide works only under direction and close supervision of an OT practitioner (OT or OTA) and provides supportive services: "Aides do not provide skilled occupational therapy services" (p. 666).³ Aides may perform only specific, selected, delegated tasks. Although the OTA may direct and supervise the aide, the OT is ultimately responsible for the actions of the aide. Tasks that might be delegated to an aide include transporting clients, setting up equipment, preparing supplies, and performing simple and routine client services for which the aide has been trained. Individual jurisdictions and healthcare regulatory bodies may restrict aides from providing client care services; reimbursement may also be denied for some services provided by aides. Where permitted, the OT may delegate routine tasks to aides to increase productivity.⁷

Teamwork with Other Professionals

Many healthcare workers collaborate in the care of persons with physical disabilities. Depending on the setting, the OT may work together with physical therapists (PT), speech and language pathologists (SLP), activity therapists, recreational therapists, nurses, vocational counselors, psychologists, social workers, pastoral care specialists, orthotists, prosthetists, rehabilitation engineers, vendors of durable medical equipment, and physicians from many different specialties.

Relationships among and expectations of various healthcare providers are often determined by the context of care or setting. For example, in some situations, home care services are coordinated by a nurse. In a hospital or rehabilitation setting using a medical model, the physician most often directs the client care program. Some rehabilitation facilities employ a team approach to assessment and intervention, which reduces duplication of services and increases communication and collaboration. Several individuals from different professions may together perform a single evaluation. For example, the OT may be the lead member of the team

in some settings or may be the director of rehabilitation services. In a team, members adjust scheduling and expectations to collaborate with one another to promote effective client care.

Many factors affect relationships among professionals across disciplines: the intervention setting, reimbursement restrictions, licensure laws and other jurisdictional elements, and the training and experience of the individuals involved. Relationships develop over time, based on experience and interaction and sometimes on personality. Even where formal jurisdictional boundaries may appear to limit roles for OT, informal patterns often develop at variance with the prescribed rules. For example, although in some states a physician's referral may be required to initiate OT service, the physicians may expect the OT to initiate the referral and actually perform a cursory screening before the physician becomes involved. Some physicians rely on OT staff to identify those clients who are most likely to benefit from occupational therapy service, and they generate referrals upon the recommendation of the OT.

Another example in which interdisciplinary boundaries may be at variance with actual practice is in the relationships among the rehabilitation specialists of OT, PT, and SLP. By formal definition, each discipline has a designated scope of practice, with some areas of overlap and occasional dispute. The scope of occupational therapy practice is described in the Domain of the Occupational Therapy Practice Framework–2⁵ and in the AOTA document titled “Scope of Practice.”⁸ Nonetheless, it is common for practitioners to share skills and caseloads across disciplines and to train each other to provide less complex aspects of each discipline's care. Two terms used to describe this are *cross training* and *multiskilling*.

Cross training is the training of a single rehabilitation worker to provide services that would ordinarily be rendered by several different professions. Multiskilling is sometimes used synonymously with cross training but may also mean the acquisition by a single healthcare worker of many different skills. Arguments have been made for and against cross training and multiskilling.^{22,34,62,82} The consumer may benefit by having fewer healthcare providers and better integration of services. Involving fewer providers may reduce costs.

The disadvantages cited include the prospect of erosion of professional identity, possible risk to consumers of harm at the hands of less skilled providers, and ceding the control of individual professions to outside parties such as insurers and advocates of competing professions.

Ethics

Although the study of ethics within an OT curriculum may be addressed as a separate course or topic, clinicians encounter ethical dilemmas with surprising frequency. In an ethics survey conducted by Penny Kyler for the AOTA in 1997 and 1998,⁴⁶ clinician respondents ranked the following as

the five most frequently occurring ethics issues confronting them in practice:

1. Cost-containment policies that jeopardize client care
2. Inaccurate or inappropriate documentation
3. Improper or inadequate supervision
4. Provision of treatment to those not needing it
5. Colleagues violating client confidentiality⁴⁶

Additional concerns were related to conflict with colleagues, lack of access to OT for some consumers, and discriminatory practice. Further, 21% of clinicians reported they faced ethical dilemmas daily, 31% weekly, and 32% at least monthly.⁴⁶

The AOTA has provided several documents to assist OT practitioners in analyzing and resolving ethical questions: the “Occupational Therapy Code of Ethics and Ethics Standards,”⁴ the “Core Values and Attitudes of Occupational Therapy Practice,”² the “Standards for Continuing Competence,”¹⁰ and the “Scope of Practice.”⁸ Whereas these documents provide a basis for resolving ethical issues, practitioners may find additional resources and support if they also approach institutional ethics committees and review boards for guidance. Kyler⁴⁶ also suggests that OT practitioners act to formalize resolutions for recurring questions by engaging with peers and others to analyze and consider courses of action.

Ethical Considerations

One process of ethical decision making within clinical practice includes the following:

1. Gather sufficient data about the problem.
2. Clearly articulate the problem, including the action and consequences.
3. Analyze the problem using theoretic constructs and principles.
4. Explore practical options.
5. Select and implement an action plan to address the problem.
6. Evaluate the effectiveness of the process and outcome.

Data from Purtilo R: *Ethical dimensions in the health professions*, ed 4, St. Louis, 2011, Saunders.

Lohman et al.⁵⁰ expand the discussion of ethical practice to include the public policy arena. Instead of occupational therapy only considering ethical practice from a perspective of service delivery to an individual, they recommend the OT practitioner consider the need to influence public policy to better serve all clients.

To reiterate, OT practitioners should anticipate that they will frequently encounter ethical distress (defined as the subjective experience of discomfort originating in a conflict between ethical principles) in clinical practice. Many approaches may be useful. A plan of action for addressing

ethical distress and resolving ethical dilemmas may involve the following:

1. Reviewing AOTA guidelines^{2,4}
2. Seeking guidance from institutional ethics and review boards
3. Approaching and engaging colleagues, peers, and the community to identify and debate ethical questions and formalize resolutions

Summary

The occupational therapy process begins with referral and ends with discontinuation of service. Although discrete stages can be named and described as evaluation, intervention, and outcomes, the process is more spiraling and circular than stepwise. The processes of evaluation, intervention, and outcomes influence and interact with one another. This may look confusing to the novice, but it is actually a hallmark of clinical reasoning.

Different types of clinical reasoning are simultaneously employed to make decisions about the form and type of service provided. While logically analyzing how to proceed through the steps of therapy using procedural reasoning, the therapist also considers how best to interact with the client. Further, the therapist creates scenarios of possible future situations. The expert clinician seeks to uncover how the client understands the disability and uses a narrative or story making approach to capture the client's imagination of how therapy will benefit him or her. This process is also influenced by the pragmatic reasoning that draws attention to the demands of the current healthcare arena.

The OT profession endorses client-centered practice, engaging the client in all stages of decision making, beginning with assessment. To make this ideal, a clinical reality requires that the OT approach every client as a co-participant and assist the client in identifying and prioritizing goals and in considering and selecting intervention approaches.

The occupational therapist and occupational therapy assistant have specific responsibilities and areas of emphasis within the OT process. The OT is the manager and director of the process and delegates specific tasks and steps to the qualified OTA. Aides may also be employed to extend the reach of OT services.

Effective practice typically involves interactions with members of other professions. This requires that the OT practitioner consider the intervention setting, the scope of practice of other professions, the applicable jurisdictions and healthcare regulations, and other factors (e.g., culture, personality, and history) that affect the individual situation.

Ethical questions arise with increasing frequency in modern healthcare. The AOTA provides guidelines and other resources; practitioners are urged to consider institutional and local resources as well, and to take an active role in identifying and resolving ethical concerns.

■ SECTION 2 | Practice Settings for Physical Disabilities

WINIFRED SCHULTZ-KROHN,
HEIDI MCHUGH PENDLETON,
with contributions from
MAUREEN MICHELE MATTHEWS,
MICHELLE TIPTON-BURTON

Individuals who have a physical disability receive occupational therapy services in a variety of settings. These may include acute care hospitals, acute inpatient rehabilitation, subacute rehabilitation, outpatient clinics, skilled nursing facilities, assistive living units, home health, day treatment, community care programs, and work sites. Regardless of the physical setting in which services are delivered, the OT should always focus on enhancing occupational performance to support participation across contexts. The OT practitioner needs to be mindful of the supports and constraints encountered in the various practice settings.

A practice setting refers to the environment in which OT intervention occurs, an environment that includes the physical facility or structure along with the social, economic, cultural, and political situation that surrounds it. Several factors influence the delivery of OT service within a specific practice setting including the following: (1) government regulations, (2) the economic realities of reimbursement rules, (3) the workplace pressures of critical pathways and other clinical protocols, (4) the range of services that are considered customary and reasonable, and (5) the traditions and culture that the staff have developed over time.

In addition, there are physical aspects such as the building itself, the temperature and humidity of the air, the colors and materials that are used, the layout of the space, and the furnishings and lighting. Practitioners must always be aware that context influences client performance in evaluation and intervention. The practice setting also influences the type of intervention available.⁶⁰ Length of stay (LOS) and limitations on the numbers of visits require the OT practitioner to carefully examine intervention that can produce outcomes within the allotted time. Each practice setting has unique physical, social, and cultural circumstances that influence the individual's ability to engage in occupations or activities. These environmental features are important to consider when projecting how the client will perform in another setting. For example, individuals who are in control in their home environment may abdicate control for even simple decisions in an acute care hospital, giving the erroneous impression of being passive and indecisive.¹⁶ The following section describes the typical practice settings in which OT services are provided for persons with physical disabilities. Table 3-2 provides a comparison of the approaches used at the various settings, the length of time services are provided, and the frequency of services. Notice that although the typical client conditions do not substantially change across settings, the approaches change to meet

■ **TABLE 3-2** | Comparison of Practice Settings

Practice Setting	Length of Time Services Are Provided	Examples of Client Conditions Needing OT Services	Examples of Typical OT Approaches Used in the Setting	Frequency of Services
Acute care hospitalization	Days to 1 or 2 weeks	Acute injuries and illnesses, exacerbations of chronic conditions	Restore ability or skill, modify the activity or context, prevent further disability with an emphasis on discharge setting	Daily
Acute rehabilitation	Weeks	Neurologic, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability with emphasis on occupational performance	Daily, 3 hours a day
Subacute rehabilitation	Weeks to months	Neurologic, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability with emphasis on occupational performance	Daily to weekly
Skilled nursing facilities	Months to years	Neurologic, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability, preserve current skills	Daily, weekly, monthly consultation
Home- and community-based settings	Weeks to months	Neurologic, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability with emphasis on occupational performance	Daily to weekly
Residential care and ALUs	Months to years	Neurologic, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability, preserve current skills, promote health	Weekly, monthly consultation
Home healthcare	Weeks to months	Neurologic, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability	Weekly
Outpatient	Weeks to months	Neurologic, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability with emphasis on occupational performance	Weekly
Day treatment	Months to years	Neurologic, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability, preserve current skills, promote health	Daily, weekly
Work site	Weeks to months	Neurologic, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability with emphasis on occupational performance	Weekly, monthly consultation

the client's needs. Suggestions for modifications of the therapeutic environment and clinical approach are given.

Continuum of Healthcare

The variety of settings forms a continuum of care, albeit not always in a sequential fashion, for the client who has a physical disability. Persons with physical disabilities who are referred to occupational therapy services may enter the

healthcare system at any point on the continuum and do not necessarily follow a direct progression through the various settings described here. A client in an acute hospital might be referred for bed mobility, transfers, and self-care retraining. Depending on the severity of the condition and the potential to improve, the client may be seen in a rehabilitation or day treatment program. A home health or outpatient therapist may see the same individual to address unresolved problems and modify the home environment to

maximize occupational performance. Should the client return to the workforce, he or she may benefit from occupational therapy services, such as an assessment and recommendations about modifications to the work environment or job tasks (see Chapter 14). Evidence has demonstrated the effectiveness of OT services in helping individuals return to work after they have experienced a disabling condition.⁵² Some hospitals offer a range of healthcare services from an emergency room and acute care or intensive care unit (ICU) to inpatient and outpatient rehabilitation services. Other settings may offer only outpatient rehabilitation services.

Inpatient Settings

Settings in which the client receives nursing and other healthcare services while staying overnight are classified as inpatient settings.

Acute Care Inpatient Setting

Clients in an acute care inpatient setting typically have a new medical condition, such as a heart attack, burn, cerebrovascular accident (CVA), or a traumatic brain injury (TBI), that led to hospitalization or an exacerbation of a chronic condition, for example multiple sclerosis. An acute decline in a chronically progressive condition abruptly confronts the client with a long-term prognosis of increasing disability. The client may require life support because of the severity of the condition. Terminally ill clients who have managed in their own home with support from a hospice program may require acute hospitalization for pain management, placement, or imminent death; in such cases, a client's hospice goals should be clearly stated and respected by the hospital staff. (For additional information on hospice care, see the section on skilled nursing facilities later in this chapter.)

Acute hospitalization, especially when unplanned, results in a sudden change in the client's environmental supports and context(s). Previous social roles may be abandoned when the person becomes hospitalized. External stressors such as financial issues or disruption of career and educational pursuits must be considered when providing services in an acute care setting. An individual who felt in control of his or her life becomes controlled by the circumstances requiring the hospitalization. Nora had a sudden change in her ability to control her environment and exercise her role as a wife and mother. When she sustained her TBI, she was admitted through the emergency room, hospitalized in an ICU to stabilize her condition, and had both a nasogastric (NG) tube and a catheter inserted. On the second day in the ICU, the occupational therapist evaluated Nora's ability to manage oral secretions and swallow her own saliva. She would continue to receive the majority of her nutrition through the NG tube but was cleared to begin to eat thick liquids such as nectar. When her vital signs stabilized on day 3, she was transferred to an acute rehabilitation setting for continued therapy services.

Three general roles have been identified for the occupational therapist working in the acute care setting: education, initiation of the rehabilitation process, and consultation.¹⁴ Education may address safety precautions and activity analysis. Rehabilitation services may be initiated for clients who will be transferred to a rehabilitation facility. Consultation is focused on the discharge environment and client needs after leaving the acute care hospital. An experienced occupational therapist, equipped with knowledge of available resources in the hospital and community, can offer a better coordinated and efficient intervention plan to promote client progress and anticipate outcomes. For example, a therapist who determines that a client living alone at discharge would be unable to prepare meals should contact the social worker who would help arrange for the delivery of meals to the home. Another example is a therapist who evaluates a client scheduled for imminent discharge and finds that the client is impulsive, lacks insight into the consequences of his or her actions, and is confused when performing self-care tasks. In this instance, the therapist expresses these concerns to the discharge coordinator or the physician. The social worker might be consulted about family support available, or discharge may be delayed to determine if appropriate environmental supports are available for the client.

Acute hospitalizations are frequently stressful and frustrating for clients. Away from home while ill, subjected to multiple tests and examinations with sleep interrupted, clients are in a socially compromised environment. They may experience sleep deprivation and overstimulation because of the frequency of procedures or interventions. Some clients, after 2 or 3 days in the ICU, may display marked difficulties with orientation, appearing confused, agitated, and disorganized.⁶¹ This has been referred to as ICU psychosis, and clients may experience hallucinations in addition to anxiety and confusion. The client's history should be reviewed to determine if previous episodes of disorientation and confusion were present or if they are produced by the disorienting effects of being hospitalized in an ICU. Concerns as to whether they might be able to return home after the hospitalization, who will help with care, or who is helping care for dependent loved ones may add to clients' feelings of stress.

The acute hospitalization has many physical environmental factors that present a challenge to clients. Often clients have several monitors in place or tubes inserted such as oxygen saturation monitors, cardiac monitors, arterial lines, and catheters that may compromise engagement in occupations.⁴⁰ The arrangement of the hospital rooms and extra equipment can further impact the client's occupational performance. The absence of carpeting and the presence of a slippery floor surface may prove challenging for clients during a transfer and when walking. The incidence of falls in the geriatric population is higher in acute hospitals than in either the community or skilled nursing facilities.²⁰

Providing OT intervention services in an acute care setting may be challenging for therapists, because it is often necessary to perform assessments in client rooms rather than in more natural environments designed for ADLs. Performance of various activities may be influenced by catheters, feeding tubes, or monitors. Likewise, client performance in some self-care activities may be artificially enhanced by a lack of the extraneous stimuli found in the home and by the physical attributes of hospital equipment. For example, a client whose home includes three very active cats, several throw rugs on a slippery floor, a very soft bed several feet from the bathroom, and a tiny bathroom faces far more challenges to get up in the middle of the night to use the toilet when compared to the same activity performed in the hospital. The hospital has no throw rugs or active cats as obstacles and often the bathroom is adapted to support safety and performance in toileting. To partially replicate the home environment during the intervention session, the therapist might position the client's bed flat, eliminate the bed rails, and lower the bed to better simulate the client's home. Most hospitals would not allow further challenges such as bringing a cat into the room or scattering throw rugs on the floor as an obstacle for the client. Using clinical experience and judgment, along with information provided by the client regarding the home environment, the therapist must be able to anticipate the client's performance at home. However, referral to a home health therapist is also advisable to assess occupational performance and accessibility in the client's home.

The acute care hospital also presents the occupational therapist with unique economic, social, and physical challenges. Medical intervention is directed toward promoting medical stability and providing for safe, expedient discharge. It is not unusual for the individual in acute care to receive OT services for the first time on the day of discharge. During this single visit, the therapist must communicate the role of OT, establish an occupational profile, and assist the client in identifying problems and assets in the discharge environment. The client and the family frequently look to the therapist to identify what the client will need at home. The therapist, in collaboration with the client and family, must develop intervention priorities by identifying issues and concerns after discharge from the acute care setting. The intervention plan may include purchase of durable medical equipment and referral for further intervention to inpatient rehabilitation, a skilled nursing facility, an outpatient clinic, or home health therapy providers. By contacting other members of the healthcare team and communicating concerns, the therapist can facilitate implementation of the recommendations.

Inpatient Rehabilitation Setting

Clients may be admitted to an inpatient rehabilitation unit when they are able to tolerate several (usually 3) hours of therapy per day and are deemed capable of benefiting from

rehabilitation. Rehabilitation settings may be classified as acute or subacute (discussed later). Clients are generally medically stable in this setting and require less acute medical care when compared to services provided in an acute care hospital. Pain, which may be present and affecting client performance, should be addressed in this setting. Performance in ADLs will reflect the client's adaptation to pain, and the energy expended to perform self-care tasks should be considered (see [Chapter 28](#) for a further discussion of pain).

During Nora's acute rehabilitation hospitalization she received occupational therapy services twice a day along with daily services from a speech and language pathologist and a physical therapist. These services were coordinated to support client outcomes. As is common during acute rehabilitation hospitalization, Nora was expected to dress in her typical street clothing and eat meals at a table in a dining area. This environmental feature of the acute rehabilitation setting provides a social element that is not present in the acute care hospital.

Acute Rehabilitation

When clients are medically stable and able to tolerate 3 hours of combined therapy services for 5 to 6 days a week, they may be transferred to an acute inpatient rehabilitation setting. Clients may still require some level of acute medical care in this setting. The length of stay (LOS) in acute rehabilitation settings generally ranges from 2 to 3 weeks, but it varies according to the client's needs. The usual discharge plan from acute rehabilitation is to a lesser level of care (e.g., residential care or the client's home with assistance such as a home health aide or personal care attendant).

The process of adjusting to disability has begun by the time the client enters acute rehabilitation. As the client begins to participate in areas of occupation, deficits and strengths become more defined. An improvement in the client's function from the onset of the disabling condition may have occurred. Within a rehabilitation center, many clients form new social relationships with individuals who have similar disabilities. The advantages of these relationships are emotional support and encouragement from the progress of others. In rehabilitation, interventions are focused on resuming those roles and occupations deemed important to the client's life. For example, an adolescent will reestablish social roles with peers; a parent will resume childcare responsibilities.

Although bedrooms in acute inpatient rehabilitation settings are similar to those found in acute care hospitals, clients are often encouraged to personalize their room by having family and friends bring in pictures, comforters, and other items from home. In this setting, clients are expected to wear street clothes rather than pajamas. The clothing that clients most often select is easy-to-don leisure wear. The OT practitioner must consider the range of clothing the client will be expected to wear to resume his or her occupational roles upon discharge and include training with appropriate

clothes such as neckties, button-front shirts, and pantyhose if necessary.

Simulated living environments, family rooms, kitchens, bathrooms, and laundry facilities can be found at most rehabilitation centers. These environments may be inaccurate replicas of the client's home. For example, laundry machines may be side-by-side and top-loading versions rather than coin-operated and front-loading machines. Kitchens may be wheelchair accessible in the facility but inaccessible in the home. Clutter, noise, and types of appliances encountered in the rehabilitation setting often vary from the client's natural environment.

Access to the community is not generally evaluated during the acute rehabilitation hospitalization. Some urban facilities are able to integrate community training more smoothly because stores, restaurants, and theaters are located near the hospital. Although the community surrounding the hospital may differ from the client's neighborhood, this offers an opportunity to experience a more natural environment.

The culture of rehabilitation facilities is focused on client performance and goal attainment. The client's own culture may be compromised in the process of rehabilitation unless the team is sensitive to and incorporates client's perspective into the intervention plan.¹⁷ For example, some cultures view hospital settings as a place for respite and passive client involvement. Engaging clients in ADLs can be in direct conflict with client and family expectations. When cultural perspectives clash, unrealistic goals may result. As is the case in any setting, meeting the established outcomes is dependent on clear communication and the identification of goals that are relevant and meaningful to the client.⁷¹

Upon completion of the acute inpatient rehabilitation program, some clients return home and receive home health services. Unfortunately, not all clients eligible to receive home health services are referred for these services.⁵⁸ The occupational therapist should actively participate in discharge planning for clients to ensure they receive the necessary services when discharged from the acute rehabilitation setting. Clients are also referred to a subacute rehabilitation setting upon discharge from the acute rehabilitation hospitalization for continued services. There are several similarities between the acute and subacute rehabilitation settings. The primary differences found in subacute settings are discussed in the following section.

Subacute Rehabilitation

Subacute rehabilitation facilities are found in skilled nursing facilities and other facilities that do not provide acute medical care. The equipment available to the occupational therapist for intervention and evaluation in the subacute setting may be comparable to that found in the acute rehabilitation facility. The focus of intervention continues to address restoring functional abilities, but with the slower rate of change the occupational therapist must also consider the need to adapt or modify the environment to promote

occupational performance. Lengths of stay in the subacute setting vary, and stays may last from a week to several months. This setting is also known as a short-term skilled nursing facility admission. Clients are usually discharged to a lesser level of care when they leave a subacute rehabilitation setting.

The pace of intervention services varies, and engaging in 3 hours of therapy per day is not mandatory. Client endurance will influence the frequency and duration of therapies. A client may continue to make steady gains but at a slower pace than was seen during the acute inpatient rehabilitation stay.

Because many subacute rehabilitation programs are located in skilled nursing facilities, the client may have roommates who are convalescing rather than actively participating in rehabilitation services. This presents as an additional variable to be considered in the intervention plan because the social context does not always support participation in the rehabilitation services provided at the setting. Staff may be more oriented to the skilled nursing care services and not allocate similar efforts toward the rehabilitation goals of independence.

Skilled Nursing Facilities

A skilled nursing facility (SNF) is an institution that meets Medicare or Medicaid criteria for skilled nursing care, including rehabilitation services. Although subacute and short-term rehabilitation programs may be housed in SNFs, occupational therapy services are also provided to individuals who are not in a subacute rehabilitation program. They are known as long-term skilled programs. Many residents (the preferred consumer label for persons who live in long-term care settings) will remain in SNFs for the remainder of their lives; others will be discharged home.¹³ Goals should be directed toward independence and meaningful occupational pursuits and may include fostering engagement in occupations through environmental modifications and adaptations. An example would be reading materials and playing cards with enlarged print to foster leisure pursuits for clients with macular degeneration. Hospice services may be included in this setting if appropriate.⁷⁸ Hospice care requires the physician to document that the client "probably has 6 months or fewer to live" (p. 8).⁷⁸ The services provided do not focus on rehabilitation but instead address palliative care and environmental modifications. Occupational therapy services for hospice clients should address access to the environment and participation in occupation through support and modifications. For example, occupational therapy services could address participation in leisure pursuits as a hospice client creates a memory book for significant others.

The physical and social environment in skilled nursing facilities may impede the natural performance of ADLs. Clients often receive additional assistance with self-care tasks to expedite task completion, but this assistance is not focused on fostering engagement in occupational

performance.⁷⁰ An investigation within SNFs demonstrated that even clients who were severely cognitively impaired benefited from intervention that was focused on fostering client participation in ADLs. Not only did clients increase participation in self-care tasks but there was also a reduction in disruptive behavior.

Extreme variations in disability status are present in SNFs. Observing residents who are severely and permanently disabled may lead newly disabled individuals to form negative expectations of their own prognosis and performance. Younger adults placed in SNFs (where most residents are older adults) may feel isolated and abandoned, which can adversely affect performance. Friends are less likely to visit in this environment. Family and friends may expect less of the individual than they would in other settings. Maintaining connections with friends from the community may require the client to actively pursue these relations. A therapist who facilitates identification of realistic and meaningful expectations and goals with the resident can promote a more positive outlook and outcome. A strong family commitment can support outside relationships by providing transportation to various community gatherings.

Community-Based Settings

These settings often afford the therapist access to the client's natural physical, social, and cultural environments. Services provided in community settings can foster not only skill acquisition and habit formation but also engagement in occupations in natural environments. Community-based settings may include a residential aspect but the client is not hospitalized. Clients also reside in their home when receiving community-based services.

Home- and Community-Based Settings

An alternative to an acute inpatient rehabilitation program for clients with traumatic injuries such as head or spinal cord injuries is a home- and community-based therapy program. This type of program provides intensive rehabilitation in the client's own home and community. The client receives comprehensive rehabilitation services and acquires functional skills in daily activities in the normal environments of home, school, work site, and community. This enhances the likelihood of a successful and functional outcome.

For example, Nora may benefit more from working on tasks in her home and community than in a clinic or acute rehabilitation setting. The client is performing in her natural physical, social, and cultural environment. Scheduling is within control of the client, and intervention sessions vary in length and frequency depending on the goals. An all-morning session to work with the client as she moves through her daily routine (e.g., bathing and dressing her child, going grocery shopping, and performing various household chores) would be possible.

OT Practice Note

The therapist must be able to adapt the intervention to the natural social and cultural aspects present in the home. Attempts to alter the natural social and cultural order are ill advised, because things are likely to return to their natural state when the session ends and the therapist leaves.

When practice is necessary for goal attainment, a rehabilitation technician or therapy aide may be charged with carrying out specific and limited programs established by the therapist. The technician who spends many hours with the client can provide insight when the program is not succeeding because it interferes with the natural context of the client's lifestyle. Adjusting intervention strategies to adapt to these lifestyle differences will ensure better clinical outcomes.

Intermediate Care Facilities (Residential Care)

Generally, residential facilities more closely resemble home situations; persons may reside there on a permanent or transitional basis, depending on prognosis.⁶⁴ Similarities in the age of residents, their disability status, and even diagnoses are commonly present. Although clients do not require ongoing intensive medical care, the facilities are staffed with care providers 24 hours a day because of the clients' need for safety and supervision. OT services may not be available on a daily basis, and rehabilitation technicians may implement the unskilled portions of the intervention plans addressing ADLs, select IADLs, and leisure. Often clients require ongoing assistance for portions of these tasks, and personal care attendants or technicians complete portions of the activity or task. The therapist can identify key performance issues in this context. Difficulties with evening self-care, follow-through with safety guidelines, problem solving, schedules, and client performance are reviewed and discussed with the OT. Modifications in the intervention plan can be more easily tailored to promote independence under such close supervision.

Assisted Living Units or Residence

An assisted living unit (ALU) provides health services in a cooperative living setting. A client may live in an apartment or cottage where one or more meals are provided on a daily basis, medication management is provided as needed, and 24-hour support is available. These settings usually have age restrictions and residents must be over the age of 55 years old, or if a couple, one person must be over the age of 55. The client generally does not plan or anticipate a move to another type of setting and is often expected to own or rent the living space in the ALU. Because there is an age restriction for most ALUs, the social and environmental support

is present to preserve living in one's own space. For example, apartments or cottages may be equipped with safety railings in the bathroom and walk-in closets for ease of accessibility.

In this setting, occupational therapy services are provided to foster and enhance the habits and routines necessary to remain housed in this environment, which often includes personal care skills such as dressing, grooming, hygiene, and simple home care tasks. Some household tasks may be partially assumed by the services provided in the assisted living setting. For example, an ALU may provide a service of laundering towels and bed linen, but the individual is responsible for the care of his or her own clothing items. Some ALU settings provide all meals, whereas other settings provide only one meal and the individual will need simple meal preparation skills to live in that setting. It is important for the OT to determine what services are available at the ALU prior to designing an intervention plan with the client. An important occupational pursuit for those in this setting would be leisure activities. Environmental supports such as magnifiers for reading, enlarged print playing cards, and a universal remote to access the television may provide opportunities for leisure activities in this setting.

Home Health

Home healthcare provides services within the client's home and affords the most natural context for intervention. The desired outcome for services provided within the home could include supported completion of ADLs or IADLs such as bathing, dressing, and meal preparation. The client, returning home from the hospital, begins to resume life roles at home. The focus of occupational therapy intervention would be to support participation in those roles.⁷⁷

A visiting therapist is a guest in the client's home and is subject to certain social rules associated with guests. For example, the family may practice the custom of removing street shoes within the home and the therapist should respect and comply with this practice. The client and family establish daily schedules for meals, waking, and sleeping. Appointments should support the family's routines and not interfere with daily schedules. For example, if the client is accustomed to eating a larger meal during the middle of the day and a very small evening meal, an intervention to address meal preparation skills should be scheduled to support this routine.

Self-care, homemaking, and cooking tasks evaluated in the context of the home clearly identify the challenges that the client meets daily. The familiar clothing, furniture, appliances, and utensils used in everyday life are present and promote orientation and task performance. However, moving of furniture to make things more accessible and safe for the client or modifying equipment to be used within the home may challenge orientation skills and increase confusion. Caring for and feeding pets, answering the door safely, and determining a grocery list for the week are

potential issues to be addressed within the home setting. Self-care tasks such as bathing can be addressed within the natural environment and when appropriate modifications to the home are made, the client's dependence on others may decrease.³⁰

Social and family support, or lack thereof, is readily evident to the home health therapist. Individuals who appeared alone and unsupported while hospitalized may have a network of friends and family members who lend support at home. Conversely, other individuals who had frequent visitors in the hospital may be abandoned when the realities of disability reach the home setting.

The client who receives home health services typically requires assistance for some aspects of his or her ADLs. Nearly 20% of all family caregivers are employed full-time outside the home.¹¹ These caregivers are available for only part of the client's day and will be concerned primarily with the safety of the client during their absence.

Stress is common among caregivers. Respite care, which temporarily places the client under the care and supervision of an alternative caregiver for a few hours and up to several days, can provide necessary relief for a caregiver.¹¹ Caring for a person with a disability in one's home is not an easy task. Box 3-2 identifies practical concerns surrounding the presence of a client in the home. By providing individualized occupational therapy recommendations for home modifications, caregiver approaches, and community-based resources for clients who had Alzheimer's disease, caregivers reported a decrease in a sense of burden and improved quality of life.²⁵

■ Box 3-2

Concerns in Caring for a Person with Disability in One's Home

Amount and Type of Care Needed

Long-term versus temporary, intensive supervision or assistance versus minimal, help available to the caregiver, presence of alternative solutions, and personal feelings about the client and the type of care required (intimate assistance versus household tasks).

Impact on the Household

Effect on spouses, children, and others living in the home; possible involvement of family in making decisions.

Environmental Concerns

Need and possibility of adapting the home, expenses of adaptations.

Work and Finance

Options for family medical leave; ability and need to quit work; benefits available.

Adapted from Visiting Nurses Association of America: *Caregiver's handbook: a complete guide to home medical care*, New York, 1997, DK Publishing.

When viewing the client's home environment, the therapist can make recommendations for environmental adaptations, see them implemented, and modify those changes as needed to best meet the client's needs.³⁹ Physical changes to the home, including moving furniture, dishes, or bathing supplies, should not be undertaken without the permission of the client and are best considered through a team approach to support the collaboration between professionals and client.⁶⁵ If the client is in the home of a family member or friend, the permission of the homeowner must also be sought.

The client and family are in control of the home environment. Clinicians who fail to ask permission before adapting the environment will rapidly alienate their clients. A throw rug, viewed by the therapist as a tripping hazard, may be a precious memoir from the client's childhood home. In seeking permission of the client and family and providing options, the therapist opens communication. An adhesive mat placed beneath the throw rug will provide a safer surface on which to walk. Another possible solution is to hang the rug as a wall tapestry, where it will be more visually prominent and less prone to damage.

Healthcare workers in the home occasionally encounter ethical dilemmas, typically involving safety.⁵⁹ The therapist must determine the best method for resolving issues of safety hazards. Fire and health hazards must be discussed and corrected when the safety of the client or adjacent households is in jeopardy. By broaching the subject diplomatically and directly, the therapist can address most hazards and provide acceptable solutions. Inclusion of the client, family, and other team members in the process of problem identification and solution generation is strongly recommended.

When Nora returned home after her acute rehabilitation hospitalization, Sheena arranged for her to receive OT services through a home health agency. Nora, Sheena, and the home health OT identified concerns with meal preparation, laundry, and playing with her children as important occupations to be addressed. Sheena was not able to make a home visit prior to Nora's discharge from the acute rehabilitation program but was able to coordinate continued services through the home health agency. The home health OT worked with Nora on strategies to improve her safety in meal preparation, helped her to simplify her laundry and cleaning routines, and provided suggestions for leisure activities in which Nora could engage with her children in the home.

Outpatient Settings

Outpatient OT service is provided in hospitals and free-standing clinics to clients who reside elsewhere. Clients receiving services in this setting are medically stable and able to tolerate a few hours of therapy and travel to an outpatient clinic. Although many clients are adjusting to a new disability, some persons with long-standing disability may be referred for reevaluations of functional status and

equipment-related issues. The frequency of services provided in this setting varies substantially, with some clients receiving services several times a week and other clients seen once every few months. The frequency of service is determined by the client's needs and the services offered at the outpatient clinic.

Clients exert more control over outpatient therapy schedules when compared to inpatient therapy schedules. Transportation issues and pressing family matters necessitate that clinics offer a variety of times from which a client may choose. Otherwise, the client may select a different clinic or choose to forego therapy.

To evaluate a client's performance of ADLs or IADLs in an outpatient setting, the therapist must extrapolate how task performance would occur at home.⁷⁰ Engaging in self-care tasks in an outpatient clinic may be awkward for the client. Individuals who have been assisted with bathing and dressing before coming to the clinic may resist working on these same tasks during therapy. The more contrived and inappropriate a task and context seem to clients, the less likely they will perform well and benefit from services addressing those needs.

The physical design and equipment seen in outpatient clinics vary to meet the intervention needs of specific disabilities. Hand therapy programs, for example, will have treatment tables for exercise and activities and areas for splint fabrication. A clinic designed to address industrial work is often equipped with special exercise equipment such as Baltimore Therapeutic Equipment (BTE), which mimics work tasks. Less commonly found in the outpatient setting are complete kitchens with cooking equipment and therapeutic apartments with bathing facilities, living rooms, and bedrooms.

The social context found in outpatient programs is quite distinctive. The client has begun to resume life in the home and community and may be newly aware of problems not previously foreseen or acknowledged. If the therapist is viewed as an ally in resolving problems and promoting a smooth transition to the home, the client or family members may easily disclose concerns. However, if the client and family fear that the client will be removed from the home because of an inability to manage there, they may actively hide concerns from the therapist. In the former instance the client and family view themselves as being in control of the situation. In the latter, control and power are assumed to belong to the healthcare professional. An outpatient therapist must be skilled in empowering the client. Soliciting client opinion and listening for unspoken needs are two methods for increasing the client's sense of control.³⁹ Providing choices for intervention does much to motivate clients and improve performance in desired tasks.

Day Treatment

Day treatment programs are becoming more popular as a community-based intervention setting. Programs vary, but the underlying philosophy is to provide an intensive

interdisciplinary intervention for clients who do not need to be hospitalized.³⁶ Clients receiving day treatment typically live at home but frequently require support and assistance for ADLs or IADLs. Most programs offer a team approach. Professionals from all disciplines are engaged cooperatively, sharing their expertise to meet the client's individual goals. Clients may seek services from a day treatment program to further recover functional skills following an acute injury or illness such as a TBI or CVA, or clients with a progressively deteriorating disorder, such as Parkinson's disease or Alzheimer's disease, may benefit from a day treatment program to foster continued participation in occupations through environmental modifications and adaptations.

Many day treatment programs are designed without the time constraints seen in many outpatient programs. Lengthy community outings and home and work site intervention sessions may be used as a method of attaining goals. In a day treatment setting, the occupational therapist may have the best opportunity to evaluate and provide intervention for clients in all of their natural environments.

Work Site Therapy Settings

Industrial rehabilitation can be conducted in the context of the employee's place of work. Work site therapy programs are designed to address an employee's therapy needs related to work injury. The injured worker receives intervention to foster the occupational performance necessary in the workplace, which may include work hardening, back safety, energy conservation, and work simplification techniques. This approach places the client back into the work role. Prevention of further injury occurs in a more natural context when employees are treated at the work site.

Providing OT services to individuals at their place of work helps them make the transition from the patient role to the role of worker. The therapist providing service at the work site must avoid compromising the worker's status.³⁸ The employer and peers view the employee as a worker rather than as a client. Maintaining confidentiality can be challenging because the coworkers' curiosity is often aroused by the unfamiliar face of the therapist in the workplace. The therapist should remember never to answer queries that would compromise client-therapist confidentiality. Unsolicited requests from coworkers for medical advice and work site modifications are best referred to that employee's doctor or manager.

In the work setting, the therapist interacts not only with the client but also the employer and often the insurance company. By encouraging the injured employee to communicate his or her needs for work modification and how productivity might be maintained, the therapist will pave the way for a successful transition to work. The therapist strives to balance the needs of both the employee and employer while promoting resolution of work-related issues that would interfere with a smooth transition to productive work. Scheduling of therapy visits to the workplace should

meet the needs of both the employee and employer. Work site visits should be scheduled in a manner that minimizes interfering with the natural flow of work.

The financial impact of work modifications will concern the employer. Employers do not have unlimited resources for modifying work environments. Only reasonable and necessary work modifications should be considered. Suggestions for work modifications that have an associated cost should be discussed with the employer. The therapist can suggest work modifications but must also consider the impact of these modifications on coworkers using the same equipment. As a general rule, modifications that affect workers other than the employee must be discussed with management before they are presented to the employee as possible options.

In a traditional clinic setting, a secretary who sustained a repetitive motion injury of her wrist may receive various modalities to control her symptoms of pain and edema and may be educated on joint and tendon protection techniques while performing various movements. When the secretary receives occupational therapy services in her work environment, additional benefits often occur. Joint and tendon protection techniques are applied at work while performing day-to-day work tasks. Because the client's injury occurred at work, it could be exacerbated or prevented at work. See also Chapters 14 and 15 with regard to the role of the occupational therapist in relation to workers and work settings.

Emerging Practice: Telemedicine

Telemedicine is the use of "electronic information and communications technologies to provide and support healthcare when distance separates the participants."³⁷ This approach can be effectively used to meet the needs of clients who live in rural settings where it would be difficult to receive the needed OT services.²⁶ AOTA⁹ has created a document discussing the use of telemedicine for both evaluation and intervention along with ethical considerations.

Summary

Practice settings, the environment in which intervention occurs, have temporal, social, cultural, and physical contextual dimensions that affect both the therapist and the person receiving therapy services. Knowing the features of each practice setting and anticipating how the context will affect occupational performance prepares the therapist to best meet client needs. The continuum of care must be considered as the occupational therapist develops the intervention plan with the client in a specific intervention setting. A skilled therapist collaborates with the client to develop meaningful and attainable goals and then clearly communicates those goals from one setting to the next to foster meaningful outcomes. Sensitivity to the unique needs of each individual in each practice setting is critical.

Review Questions

1. What are the major functions of the OT process?
2. How are the various forms of clinical reasoning used to guide the OT process?
3. How do theories, models of practice, and frames of reference inform and support OT intervention?
4. What is the appropriate delegation of responsibility among the various levels of OT practitioners (OT and OTA)?
5. What services may be assigned to the OT aide? What are the limits, and why?
6. How should OT practitioners effectively collaborate with members of other professions involved in client care?
7. What are some of the ethical dilemmas that occur frequently in OT practice, and how can these be addressed and managed?
8. What are the various practice settings for OT services in the arena of physical disabilities?
9. What types of services are typically provided in these settings?

Evidence-Based Practice for Occupational Therapy

4

LYNN GITLOW,
ELIZABETH DEPOY

■ Chapter Outline

Models of EBP

The SOTP model

Theoretical and logical foundations of SOTP

Complementarity with contemporary practice models

Summary

■ Key Terms

Evidence-based practice

Systematic OT practice

Thinking processes

Action processes

Evidence

Inductive reasoning

Deductive reasoning

Problem statement

Problem mapping

Need statement

Goals

Objectives

Process objectives

Outcome objectives

Specificity

■ Learning Objectives *After studying this chapter, the student or practitioner will be able to do the following:*

1. Distinguish among diverse models of evidence-based practice.
2. Define systematic occupational therapy practice (SOTP).
3. List, in sequence, the five steps of systematic occupational therapy practice (SOTP) and detail the content and processes of each step.
4. Compare SOTP with the OT process as articulated in the occupational therapy practice framework.

In this chapter, we present, discuss, and apply systematic occupational therapy practice (SOTP), a model that synthesizes and builds on evidence-based approaches to professional practice. The importance of systematically grounded practice is now an established concept within occupational therapy (OT) and the broader healthcare arena. The need for empirical analysis of the problems and needs that OT practitioners address continues to be emphasized at local, national, and international levels as reflected by initiatives from the American Occupational Therapy Association (AOTA) and the American Occupational Therapy Foundation (AOTF). These include, but are not limited to, the Center for Outcomes Research and Education (CORE), an

evidence-based practice forum addition to the *American Journal of Occupational Therapy*,²⁷ the Evidence Based Literature Project,²⁰ and the Evidence-Based Practice Resource Directory on AOTA's website. Educators, scholars, and practitioners increasingly discuss and encourage the use of theoretically grounded and supported OT interventions and the development of solid evidence of successful outcomes of interventions. We assert that current and ongoing systematic OT practice is needed in all professional domains (individual, group, community, agency, and government) if OT is to remain a viable and valued field that will continue to flourish in the competitive environment of managed care and fiscal scarcity.

Systematic OT practice involves the integration of research-based techniques into all elements of OT practice. This chapter provides a framework through which readers will understand and learn the research-based thinking and action processes necessary to conduct all or part of the sequence of SOTP. The chapter begins with a discussion and analysis of current models of *evidence-based practice (EBP)*. We then define systematic OT practice and proceed through the presentation and application of our model. As you will see, SOTP is valuable in all arenas of OT.

In this chapter, we present our model as a set of practice guidelines for clinical practice.

Threaded Case Study Maria, Part 1

Maria is an occupational therapist who receives a referral to treat a client who has been diagnosed with carpal tunnel syndrome. The referral states “improve hand strength to increase independence in ADLs [activities of daily living].”

Critical Thinking Questions

Think about how to answer the following questions as you proceed through this chapter.

1. How do you clarify the OT problem, and what is needed to resolve it? What evidence do you need to support your decision?
2. What factors do you need to consider in examining your professional activity and interventions, and what evidence do you need to consider?
3. How do you establish the extent to which you have determined the need and resolved the problem? What evidence do you need?

Models of EBP

Many models of evidence-based practice have been presented in the literature. Practice models that integrate multiple methods of inquiry into all domains of professional practice have been called evidence-based medicine,^{6,22,24} evidence-based practice,⁵ evidence-based rehabilitation,¹⁶ outcomes research,¹⁵ and so on. Because of the expansive literature on EBP approaches, it is beyond the scope of a single chapter to review all of the work in its entirety. Therefore, we have selected to present important definitions that have been advanced in the literature and to discuss their variations. This discussion provides a rationale for systematic OT practice, our model for the application and use of evidence-based approaches relevant to and consistent with OT practice. At this point, you may be asking, “Why create another model if there are so many”? Our approach is not entirely new. However, we developed it as a comprehensive organizational framework that sees systematic OT practice and inquiry as one in the same. In other words, following

the steps of SOTP in all professional activity leads not only to sound practice but also to the creation of OT knowledge.

Table 4-1 presents diverse approaches to evidence- and inquiry-based practice. As you read these descriptions, you will notice that each approach identifies different sources as credible evidence in three categories: client generated, professionally generated, or scientifically grounded. By client generated we mean that information put forth by the client is considered as part of the evidence base for professional interaction. Professionally generated refers to provider education and experience as a valued source of knowledge for use. Scientific evidence is that developed by rigorous methods of inquiry. Not all models may value all three sources as we depict in Table 4-1.

Ethical Considerations

Consistent with OT ethics, philosophy, values, and theory, we subscribe to the principle that it is our ethical obligation as professionals^{1,2,21} to collaborate with clients regarding all aspects of their service need, provision, risk, and outcome. Therefore, we not only support the value of evidence generated by client, practitioner, and science, but we encourage critical use of diverse sets of evidence as viable and purposive.

The SOTP Model

Building on and synthesizing the excellent work in evidence-based practice, we define *systematic OT practice* as the integration of critical, analytic, scientific thinking, and action processes throughout all phases and domains of OT practice. Let us look at this definition more closely. First, we distinguish thought and action from each other. In systematic inquiry, it is essential for the thinking sequence and its rationale to be presented clearly. Thinking processes are composed of the reasoning sequence and logic that OT practitioners use to conceptualize intervention and specify desired outcomes. *Thinking processes* involve the selection of a theoretical framework in which the OT practitioner plans the steps necessary to assess problems, evaluate intervention, specify desired outcomes, and plan a strategy to determine and systematically demonstrate the degree to which client-centered outcomes were met for an individual receiving OT services. Sometimes we are not fully aware of our thought processes, but they are there nonetheless and are the foundation of systematic OT practice, as we will see later in this chapter.

Action processes are the specific behaviors involved in implementing thinking processes.⁸ Action processes are behavioral steps. In systematic OT practice, these steps are founded on logical inquiry such that any claim is supported with empirically derived information from a variety of sources.

■ **TABLE 4-1** | Approaches to Evidence- and Inquiry-Based Practice

Author	Description	Client	Science	Profession
Sackett ²³	Evidence-based medicine is the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients. The practice of evidence-based medicine means integrating individual clinical expertise with the best available clinical evidence from systematic research.		X	X
Institute of Medicine ¹³	Evidence-based practice is the integration of best research evidence with clinical expertise and patient values.	X	X	X
Law ¹⁶ (pp. 10-11)	Evidence-based rehabilitation is a subset of EBP that consists of four concepts: (1) <i>awareness</i> —being aware of the existence of and strength of evidence in one’s field, (2) <i>consultation</i> —collaboration between the client and clinician in determining relevant problems and their clinical solutions, (3) <i>judgment</i> —being able to apply best evidence to the individual with whom you are working, and (4) <i>creativity</i> —which emphasizes that evidence-based practice is not a “cookie cutter” approach but the combination of art and science.	X	X	X
Lee and Miller ¹⁹	Process of evidence-based clinical decision making encourages us to include client and clinician “values, knowledge and experience.”			
Kielhofner, Hammel, Helfrich, et al. ¹⁵ (p. 16)	Investigation that provides evidence about the effects of services. Identifying client need. Creating the best possible services to address those needs. Generating evidence about the nature of specific services and their impact. Accumulating and evaluating a body of evidence about specific OT services.			

Although SOTP is not research in itself, it is the organized application of research to the conceptualization, enactment, and investigation of the process and outcome of intervention. OT and healthcare researchers, educators, and practitioners have identified many arenas in which EBP is valuable. Consistent with our chapter focus on clinical practice, Tickle-Degnan²⁶ stated, “Evidence based practice (EBP) is like a toolbox of methods available to the occupational therapy practitioner to aid clinical reasoning. The toolbox consists primarily of methods designed to integrate current and best evidence from research studies into the clinical reasoning process” (p. 102). We add to this description the integration of the client’s perspective throughout the process.²

What is meant by *evidence*? This question is not easily answered. Synonyms for evidence include terms such as *data*, *documentation*, *indication*, *sign*, *proof*, *authentication*, and *confirmation*. In some models of evidence-based practice, the highest evidence in the hierarchy of credibility is considered to be data that are generated by positivist, experimental-type inquiry. This perspective is reflected in the AOTA’s Evidence-Based Literature Review Project.²⁰ However, other OTs and authors suggest that a full range of methods can generate useful evidence.^{7,18}

In this chapter and in SOTP, we define evidence as information that is used to support a claim. This expansive definition allows for the identification and acceptance of a broad scope of evidence as the basis for decision making in practice as long as the evidence is identified and used within the systematic thinking and action processes that we discuss in detail here.

Ethical Considerations

Unsubstantiated beliefs or claims are insufficient in themselves to support professional activity in an increasingly competitive; quality, safety, and cost conscious; and accountability-demanding healthcare context.

Within the profession, OT practitioners can use the information obtained from SOTP not only to improve the processes and outcomes of their practices but also to engage in informed thinking when choosing among possible interventions and to contribute to the overall knowledge base of our profession. Studies of practitioners’ perceptions⁹ of evidence-based practice suggest that OT practitioners view scientific literature as a valuable resource to share with other

professionals when supporting the effectiveness of OT interventions. However, for informing intervention choice, practitioners tended to consult and depend on trusted personal sources.⁹ SOTP systematically guides practitioners in determining which interventions are effective to produce desired outcomes, which interventions need to be improved, and what kinds of new knowledge need development. Additionally, having credible evidence to demonstrate that the interventions OT practitioners use produce desirable outcomes provides concrete feedback to the consumer.^{12,27} Finally, by systematically evaluating interventions, OT practitioners can provide evidence for advancing clinical practices in the profession.

Pressures and demands on health practitioners from external sources render SOTP even more critical for three reasons. First, the location of service delivery and the time allowed for service delivery are in flux. Long-term hospital stays and treatments in acute care settings have been replaced by community-based treatment, and the length of time for delivery of treatment is shortening as third-party payers demand more efficient and cost-effective healthcare. SOTP guides the practitioner in balancing the multiple factors involved in practicing within a quality-focused fiscally driven healthcare environment. Second, by systematically examining the processes and outcomes of current practice, OT practitioners can provide an evidentiary basis for clinical thinking and action, which then can be presented to consumers, other professionals, insurers, and policy makers. Third, systematic inquiry transcends professional boundaries through shared language and theory. Within the context of physical rehabilitation, for example, the systematic foundation of the International Classification of Functioning, Disability and Health²⁸ is consistent with the Occupational Therapy Practice Framework (OTPF) and provides a common forum and language for cross-disciplinary communication.

As we proceed through SOTP, we will draw your attention to the skills and knowledge you already possess that are relevant to this conceptual approach. Let us now turn to the philosophic foundation and steps of the model.

OT Practice Notes

It is no secret that OT practitioners have always had difficulty in clearly describing what they do to those outside the profession. Moreover, OT practitioners have typically placed more emphasis on providing direct services than on publishing studies that document the results or that attribute successful outcomes to OT intervention. In today's increasingly complex and competitive healthcare environment, OT practitioners must clearly demonstrate their contribution to achieving clinical outcomes. It is particularly critical to do this if referral sources are to understand the benefits of OT to diverse client groups.

Theoretical and Logical Foundations of SOTP

SOTP is grounded in logic and the systematic thinking that undergirds all research thinking processes. Inductive and deductive reasoning methods form the basis for these thinking processes. Moreover, the two major research design traditions, naturalistic and experimental-type inquiry, are based on these logic structures.⁸ Therefore, OT practitioners must understand them and use them to guide thinking and action and to support claims regarding the process and outcomes of OT intervention.

Inductive reasoning is a thinking process whereby one begins with seemingly unrelated data and links these data together by discovering relationships and principles within the data set. In inductive systematic approaches, the data may take many forms. Inductive reasoning leads us to select naturalistic strategies, those in which theory is derived from gathered evidence rather than tested by scientific experimentation. Among the methods used in naturalistic design are interview, observation, and textual analysis.⁸ Data are collected and themes that emerge from repeated examination of the data are named, defined, and placed in a theoretical context.

Deductive reasoning begins with a theory and reduces the theory to its parts, which are then verified or discounted through examination. Deductive reasoning provides the foundation for experimental-type research, in which theories or parts are stated in measurable terms and standardized measurement forms the basis of all inquiry. Strategies used in deductive traditions include sampling, measurement, and statistical analysis. Because the rules of logic guide thinking, one can easily follow thinking processes and identify the basis on which guesses, claims, decisions, and pronouncements are made and verified.

Complementarity with Contemporary Practice Models

Although it may seem difficult at first to engage in the formal, logical thinking processes that provide the foundation for research, we do it every day. Look at how the decision-making skills used in OT practice mirror the logical thinking processes that form the foundation of SOTP. [Box 4-1](#) presents the steps of SOTP, and [Table 4-2](#) illustrates the relationship between the occupational therapy

Box 4-1

Steps in SOTP

1. Identification and clarification of the problem to be addressed by the intervention
2. Understanding of need—what is needed to resolve all or part of the problem?
3. Setting goals and objectives to address the need
4. Reflexive intervention to achieve the goals and objectives
5. Outcome assessment

TABLE 4-2 | Relationship between the OT Process and SOTP

SOTP	The OT Process/Clinical Decision Making
Initial problem statement	Referral to OT
Need statement	Systematic assessment of client/occupational profile and analysis of occupational performance
Goals and objectives	Intervention goals and objectives
Reflexive intervention	Regular progress monitoring and revision of intervention in response
Outcome assessment	Final assessment of client progress

process/clinical decision-making and systematic thinking processes.

Sequence of SOTP

Our model of SOTP has five steps, as listed in Box 4-1. The process begins with a conceptualization of the problem to be addressed. This leads to the question, “What exactly is a problem?”

Statement of the Problem

Although we often see problems as entities existing outside ourselves, problems are contextually embedded in personal and cultural values. A problem is a value judgment about what is undesirable or in need of modification. Therefore, a *problem statement* is defined as a specific claim of what is

not desired or of what should be changed. Although it seems simple to specify a problem, we often see problems stated in terms of a preferred solution; this error limits our options in analyzing problem components and solutions. Moreover, in systematic OT practice, problem statements must be derived from credible, systematically generated knowledge, including scholarly literature and inquiry, client report and data, and other sources that we discuss later in the chapter.

If proceeding from the initial problem statement in the referral, the therapist may have missed the essence of the client’s problem and thus may have selected inappropriate interventions and outcomes. The second edition of the OTPE, the OTPE-2, guides us to define problems for OT by using a client-centered approach. Thus, in SOTP, it is critical to include the client and other diverse sources of knowledge beyond practitioner guessing in formulating the problem statement.

There are many ways to identify problems. Problem mapping is a method in which one expands a problem statement beyond its initial conceptualization by asking two questions repeatedly:¹ “What caused the problem?” and “What are the consequences of the problem?”² Similar to other professionals, OTs do not address all aspects of the problem statement. *Problem mapping* helps us operationalize the OTPE in that it provides a thinking process to locate impairment and individual function within seven broad contexts: cultural, physical, social, personal, spiritual, temporal, and virtual.² As we see in the example that follows, the problem areas for OT intervention are defined by the scope of our professional activity.

Apply the problem mapping method to the statement, “Jane has impaired short-term memory resulting from traumatic brain injury sustained in an automobile accident caused by a drunk driver.” To conduct problem mapping, we first need to conceptualize the problem as a river. Articulating the original statement of the problem is analogous to stepping into the river and picking up one rock. As we look upstream, we see causes of the problem, and as we look downstream, we see the problem’s consequences. How does this mapping technique work? See Figure 4-1 to look at the problem map. Each box above the initial problem contains a possible answer to the question of what caused the problem. Once we determine first-level causes of the problem, we ask, “What caused the cause of the problem?” and so on, until we reach cultural and social value statements, both of which are specified as contexts for OT practice in the OTPE. Keep in mind that the evidence that is used to identify causes and consequences must be generated from credible, identifiable sources, including client, professional, and scientific sources.

Below the initial problem statement, we repeatedly ask the question, “What is the consequence of the problem?” As with the upstream map, this question about the consequences of consequences is repeated until we reach the effect of the problem on ourselves. At this point, you may be

Threaded Case Study
Maria, Part 2

Remember that Maria received a referral that specifies the client’s problem as “client needs to improve hand strength in order to increase independence in ADLs.” This problem as stated suggests only one solution—to increase hand strength. Through systematic thinking together with the client, Maria, however, expands her analysis of the problem to “limited hand strength does not allow the client to participate in work or self-care occupations,” which allows Maria to generate additional potential solutions. For example, the client may take the following measures: look for alternative work, increase hand strength, work with adaptive equipment, adapt the environment, and so forth. By expanding a problem statement, the OT practitioner moves beyond the obvious primary difficulty or impairment and a singular solution and can capture the breadth of focus of the problem as revealed by systematically derived evidence from literature, the client, or others.

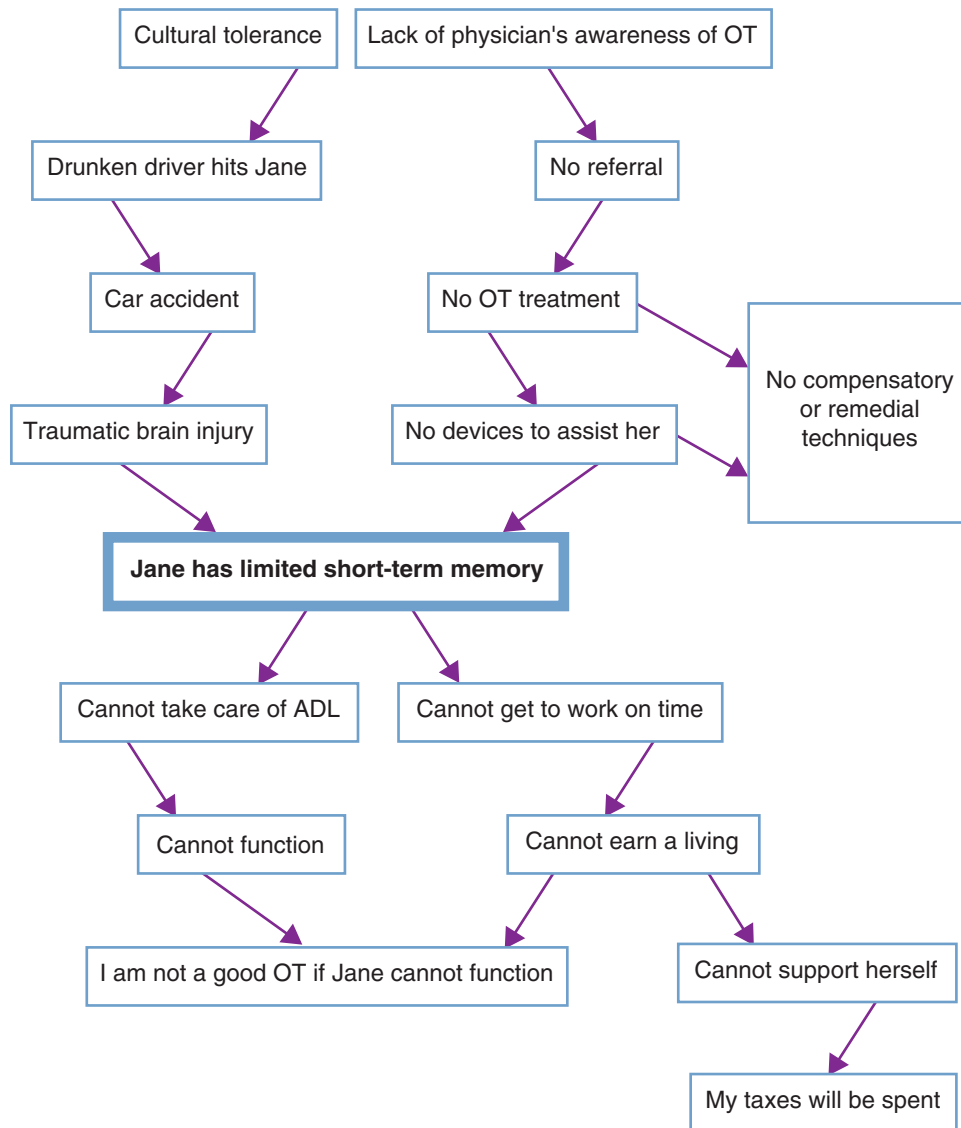

FIGURE 4-1 Problem map.

asking “why?” It is because problems are values and thus are in the eye of the beholder. The problem map expands the problem statement from documented cultural, social, and environmental causes to personal effect and suggests many different sites or targets for intervention.

As you might imagine from Jane’s example, many causes and consequences of problems are not within the scope of OT practice and thus cannot be resolved by OT intervention. Although many OT practitioners will likely expand their efforts into political action or other areas at some point in their careers, others will look for clinical interventions that can improve the occupational performance of individuals. Given the focus of this text, we will concentrate this chapter on clinical interventions rather than the other roles that OTs might assume. Jane’s problem map suggests numerous points of intervention for clinical OT in cognitive remediation, compensatory training, and provision of

assistive devices and services such as assistive technology (AT). Within our chapter the focus on clinical practice, an area of occupational performance will be considered: developing vocationally related strategies that will enable Jane to return to work. The OT practitioner could also make a referral to a social service agency for Jane, who might be eligible for social security disability income; thus, the OT practitioner would intervene, through referral to another professional on the team, at the level of Jane’s inability to support herself financially. In addition, as we look at the expanded problem, the OT practitioner may also want to intervene on the macro level by promoting stricter legislation and cultural “zero tolerance” of drunk driving, perhaps by educating adolescents and young adults. These areas of practice are beyond the scope of this chapter.

Consider the initial problem statement focusing on Jane’s impaired short-term memory. This is not a problem

that can be resolved by an OT practitioner as it is stated. Therefore, the OT in collaboration with the client must reconceptualize and restate the problem so that he or she can intervene using meaningful and systematic methods within OT's professional scope of practice.³ Problem mapping or other logical, evidence-based problem identification techniques help in examining and analyzing problems beyond their initial presentation and identifying the strength of the evidence on which problems are analyzed. In SOTP, problem analysis and a careful statement of the part of the problem to be addressed are critical if the rest of the steps are to be implemented. Including evidence from the client's perspective in the process is essential in our model. Furthermore, clarifying the problem will help the therapist ascertain what is needed to resolve the part of the problem that will be addressed.

Now let us move to the next step of SOTP, determining need.

Ascertaining Need

After problem mapping, the next step is ascertaining need. In this step, one must clarify exactly what one needs to resolve the part of the problem that has been targeted for change. Let us examine the distinction between *problem* and *need*. As discussed earlier, a problem is a value statement about what is not desired. For a problem to be relevant to OT practitioners, it must concern improvement or maintenance of occupational performance. Thus, the problem area on the map that the OT practitioner would target for resolution would be delimited and guided by the professional and theoretical domains of OT concern. A *need statement* is a systematic, evidence-based claim linked to all or part of a problem that specifies what conditions and actions are necessary to resolve the part of the problem to be addressed. Thus, the identification of need involves collecting and analyzing diverse sets of information such as assessment data and the information from the client interview, thus forming an occupational profile to ascertain what is necessary to resolve a problem.

At this needs assessment stage of the SOTP sequence, the OT may already have information on which to formulate need or may collect data in a systematic fashion to clearly delimit and identify need. A need statement should specify who is the target of the problem, what changes are desired, what degree of change is desired, and how one will recognize that the change has occurred. The need statement must be based on systematically derived data already contained in credible resources such as the relevant practice and research literature or documentation, professional education, knowledge, and experience, or revealed by the client in a needs assessment inquiry. Can you see that the need statement uses systematic research-based processes to define the next steps of specifying goals and objectives, determining the intervention, and specifying the evaluative criteria to find out if the desired outcomes of an intervention have been met?

Let us advance an example from our problem statement again. As already mentioned, the problem as stated (impaired short-term memory) is not a problem that an OT practitioner can resolve. Yet it is common for referrals for OT intervention to identify problems such as this one. Thus, the use of a problem map or similar problem analysis strategy is not only a reasonable thinking tool, but it is also essential if we are to define the nature of our interventions more clearly and thereby document the unique contributions and outcomes of OT both within and outside of our field. We thus choose to reason about the causes and consequences of the problem to identify whether an area exists in which Jane would require OT intervention. As we mapped the problem, we found that OT did indeed have a critical role to play in Jane's treatment. Her ability to engage in meaningful occupational performance is impaired in that she is unable to manage her time and arrive at work on time as a result of her impaired short-term memory.

Given the problem statement, the therapist chooses to conduct a research-based needs assessment to determine what is necessary to resolve the targeted part of the problem, to set goals and objectives to guide the selection of an intervention, and to determine what processes and outcome should be expected.

Using a systematic approach to data collection, the OT practitioner uses naturalistic techniques, including an interview and systematic observation of Jane, to ascertain Jane's desires and skills. The OT practitioner also administers a standardized cognitive assessment and an occupational performance assessment. In this instance the OT practitioner is integrating qualitative and quantitative inquiry strategies to document a complete understanding of need and to provide the empirical basis for clinical decisions, as well as expected outcomes. One of the tools that the OT practitioner may use to collect data is the Canadian Occupational Performance Measure (COPM). This criterion-referenced measure is used to identify client-perceived problems in daily functioning in the areas of self-care, productivity, and leisure. By means of a semistructured interview format, the COPM may be used to assess the performance skills and patterns the client identifies as interfering with the client's ability to function in a particular area. The data from the COPM are credible, outcome based, and accepted as evidence in the research world.¹⁷

Systematic assessment reveals that Jane identifies returning to her job as a saleswoman in a boutique as her most important goal. Additionally, the results of the COPM interview reveal that Jane is not satisfied with her ability to manage her time or her ability to be punctual and that she perceives these two issues as the greatest barriers to achieving her desired goal of returning to work. She recognizes that her difficulties with short-term memory will affect her ability to do other work-related tasks, but she reports being most concerned about time management and promptness.

Standardized testing indicates that Jane's short-term memory is impaired but that her capacity to respond well

to external cues remains intact. Additionally, Jane's performance on the Wisconsin Card Sorting Test (WCST) reveals that she is able to solve problems and that she demonstrates abstract reasoning. The WCST is a standardized cognitive assessment of executive function that was developed to assess problem solving, abstract reasoning, and the ability to shift cognitive strategies.¹¹ The results of standardized testing also suggest that Jane is able to learn new behaviors with specific, well-structured practice in the environment in which she will function. The WCST provides an assessment of cognitive flexibility and those data can be extrapolated to imply that she will be able to learn new skills in a structured environment, but the number of variables and complexity of her work setting should also be considered. Based on this empirically generated information, the therapist and Jane have a sound and credible basis for deciding that the intervention will be directed to the need to find and teach Jane compensatory strategies for time management and promptness. Further, Jane indicated in her occupational profile that she is married and that her husband would be supportive in helping her get to work.

Based on this information generated from naturalistic inquiry, the therapist and Jane decide to include Jane's husband in the intervention and to work first in Jane's home environment and then transfer her treatment to the work environment. Can you see from this example how SOTP both provides the guidance and the documentation for clinical decisions and suggests future steps in the intervention and outcome assessment processes? Anyone who observes the intervention process can easily see the rationale for decisions and actions. Credible, evidence-based knowledge is structured in a manner that provides a clear reasoning trail.

The desired outcomes are implicit in the need statement, which provides a basis for formulating measurable outcomes of intervention. According to the literature on closed head injury and professional wisdom,¹⁴ what is needed is contextually based OT intervention in the home and in the workplace to assist Jane with time management and promptness, as a skill to facilitate her return to work. The evidence for targeting this intervention and for the goals and objectives to follow is clear and specified, as is the desired outcome.

The following case example features George, another OT practitioner, and considers a different type of need statement that illustrates why OT practice requires systematic inquiry.

In needs assessment, many systematic approaches can be useful in identifying and documenting needs, including but not limited to formal research strategies, well-conducted a priori studies, or mixed methods of information gathering and analysis. For individual clinical problems, strategies such as single case design are extremely useful for guiding and testing the efficacy of intervention decisions with a client. For program development, the therapist may want to use "group" (also called nomothetic) approaches, such as

Case Study George

George, an OT practitioner, is asked by an employer to address a problem involving several computer operators whose ability to perform their jobs has been impaired or lost as a result of neck pain. After constructing a problem map based on literature about causes and consequences of neck pain, George formulates a need statement based on two areas that he believes will address the problem: instruction in proper body mechanics and instruction in a regularly scheduled upper body stretching routine. A literature review provided him with empirical evidence on which to base his intervention. He begins his intervention by teaching proper body mechanics and upper body stretching techniques to the computer operators, but the problem is not resolved. The computer operators continue to be unable to do their jobs, and their complaints of neck pain continue. George's intervention has not successfully resolved the problem for which he was hired.

What was missing from George's reasoning? He based his problem map on empirical literature and educated but preconceived guesses without fully assessing the situation. Had he conducted a systematic needs assessment that included interview, testing, and observation of the workers in the process, he might have found that the monitors were too high for the operators and the chair heights were not adjustable. Thus, the intervention of body mechanics instruction and upper body stretching that may have been viable in another situation did not address the specific needs that George failed to identify. Had he used systematic thinking and action to ascertain need rather than guessing and then jumping from the problem to the intervention, George would quickly have identified the appropriate target areas.

survey, interview, or standardized testing strategies, to yield needed information on which to support a needs claim. Naturalistic inquiry or integrated thinking and action strategies may be valuable to ascertain the perspectives of client groups about whose problems and needs the therapist knows little. Many excellent research texts exist from which to build research knowledge. (See the Suggested Readings at the end of this chapter.)

The next step in the process of systematic OT practice is translating the needs into goals and objectives.

Goals and Objectives

Goals and objectives are two words with which OT practitioners are familiar, because these concepts are used to structure treatment. In SOTP, goals and objectives emerge from the need statement and are essential not only for structuring intervention, but also for specifying how the process and outcome of intervention will be examined and supported.

A definition of the two terms is helpful. Goals are statements developed by clients and relevant others identifying the client's outcome of the service—what would the client like to be able to do or be.⁴ In other words, a goal is a vision statement about future desires that is delimited by the need that it addresses. *Objectives* are statements about both how to reach a goal and how to determine if all or part of the goal has been reached. The objective sets up the systematic approach to attaining the goal as well as the empirical measurement or assessment thereof.¹⁰

There are two basic types of objectives: process and outcome. Process objectives define concrete steps necessary to attain a goal. *Process objectives* are those interventions or services that will be provided or structured by the OT practitioner.⁷ *Outcome objectives* define the criteria that must occur or exist to determine that all or part of the goal has been reached; outcome objectives further specify how these criteria will be demonstrated. Ultimately, assessing the attainment of outcome objectives is focused on ascertaining if the desired change has taken place as a result of participation in the OT process.

To develop goal and objective statements in our model, the therapist examines the need carefully, including the evidence to support the need statement. Then, the therapist and the client formulate conceptual goal and objective statements that guide and imply how the process and outcomes of intervention will be assessed. Goals are overall conceptual statements about what is desired; objectives are statements that are operationalized (i.e., stated in terms of how they will be measured or known). Both are based on systematically generated knowledge from the needs assessment.⁷

Let us now return to Jane to illustrate goals and objectives. From the problem and need statements, we have determined that an overall goal for Jane's intervention is to develop, teach, and have Jane learn compensatory strategies for promptness and time management so she can improve her performance in these areas and return to work. Based on the evidence given in the needs assessment, the OT intervention will be carried out at first in Jane's home with her husband participating, and then a transition will be made to the workplace.

One critical element of goal setting in SOTP is *specificity*. The following example uses the treatment goal that we discussed previously as the basis for writing specific goal and objective statements.

Goal: Jane Will Improve Her Promptness to Be Able to Get to Work on Time (Performance) and to Her Satisfaction

The process (P) and outcome (O) objectives we will use to attain this goal include the following:

1. Jane will be presented with assistive technology supports and services and catalogs of assistive devices from which she can select those she thinks will be most useful for her to achieve the goal. (P)
2. Given a choice of a variety of assistive devices (e.g., alarm watches, paging devices, and clocks), Jane will choose one or more devices to use as an external cue provider for promptness. (P)
3. Jane will select one daily activity at home for which she needs an external promptness cue. (P)
4. With assistance from the OT practitioner, Jane and her husband will configure the device to cue Jane to attend to this daily event. (P)
5. Jane's husband will monitor her promptness and provide feedback to Jane and the therapist regarding the effectiveness of the assistive device in meeting the goal. (P)
6. Once Jane has demonstrated that she can promptly attend to her schedule at home, she will begin to use the promptness cue to arrive at work. (O)
7. Once Jane has demonstrated that she can arrive at work on time, the therapist will work with Jane at the work site so that she can use the device to attend promptly to her work schedule to her and her employer's satisfaction. (P)
8. Using the most effective strategy and devices, Jane will improve her promptness and satisfaction with her performance at work. (O)

As you can see by reading this goal and its related objectives, in SOTP, objectives are very directive conceptual statements designed to achieve broad goal statements based on an empirical understanding of need. As we will see in the sections on reflexive intervention and outcome assessment, stating the goals and objectives as demonstrated in this chapter determines what will be formatively monitored and examined to ascertain treatment success.

Reflexive Intervention

Extrapolated from naturalistic methods of inquiry,²⁵ DePoy and Gilson⁷ advanced the term *reflexive intervention* to highlight that systematic thinking does not cease during the implementation of interventions. We therefore have integrated this term into our model to remind us that as practice proceeds, the OT makes decisions based on feedback from the actual intervention itself, as well as from an examination of the therapeutic use of self and other influences on the intervention process. By reflexive intervention, we refer to the thinking and action strategies during the intervention phase of OT practice. In reflexive intervention, the OT systematically monitors the client, the collaboration, professional practice, setting-based resources, and therapeutic use of self and other internal and external influences that impact practice process and outcome. That is not to say that practice wisdom and intuition do not occur or are not used as evidence. Not only do they occur, but in SOTP, the OT makes it a point to be well aware of the pluralistic evidentiary basis from which he or she is making decisions, to carefully look at all practice to obtain clarity about what

was done and to consider feedback from engaging in practice.

Process assessment, the systematic monitoring of process objectives (denoted in the objective list with a P) occurs throughout the reflexive intervention phase in order to provide the evidence on which to describe intervention and the context in which the intervention occurs, as well as to yield the evidence on which decisions are made regarding the need for intervention or programmatic change. Knowing what outcomes occurred without knowing what was done to cause them limits our knowledge base and our ability to communicate the benefits of OT practice to those outside of the profession. Thus, reflexive intervention is critical to the growth of OT knowledge, theory, and practice strategies. Let us return to Jane to illustrate.

As we mentioned previously, the COPM is an excellent measure to document performance that is meaningful to the client. In process assessment, the COPM can be used to document changes in occupational performance and illustrate the benefits of OT to Jane and other diverse audiences. Using this tool to collect data at multiple points during intervention can support the intervention “as is” or reconceptualize it. The OT might also track and document Jane’s promptness over the course of her treatment to determine if revisions in the intervention are necessary. Moreover, documentation is an excellent way to show Jane and others that Jane has improved through OT. Similar strategies could be used to examine and document time management and other areas that Jane and the OT are addressing. It is useful to refer to the OTPF to guide reflexive intervention.

Outcome Assessment

Outcome assessment is a set of thinking and action processes conducted to ascertain and document what occurs as a result of being voluntarily or involuntarily exposed to a purposive intervention process and to assess the worth of an intervention. In the objective list shown earlier, outcome objectives are identified with an “O.” These objectives can be assessed by using both quantitative and naturalistic techniques and by applying systematic inquiry to examine whether objectives have been attained. To brush up on inquiry, we suggest that you consult one of the many excellent research method texts, some of which we list at the end of this chapter.

To carry out an outcome assessment of Jane’s intervention, a pre-post test design is selected using the COPM and the other documentation that we discussed in reflexive intervention. Although Jane’s performance will be measured multiple times, only the change from beginning to end will be used for outcome assessment. As you can see, all OTs already do outcome assessment. The trick is to realize that you do it and to purposefully select methods that are credible and useful. We suggest that you choose strategies that are multimethod. Look at [Box 4-2](#) to see how each objective will be assessed.

OT Practice Notes

SOTP in Professional Practice

An OT should deliberately perform each of the steps of SOTP and find a personal style for using evidence in professional practice. SOTP is not only a valuable approach in direct intervention, but it provides the foundation for knowledge building and intervention development in all professional domains.

Summary

In this chapter we presented SOTP, a practice approach in which systematic thinking and action are not only valued but are essential tools in OT practice. Our model begins with a clear problem statement that guides all of the remaining steps. Naturalistic and experimental research traditions are applied to clinical decision making to guide the subsequent steps of identifying and documenting need, positing goals and objectives, reflexive intervention, and outcome assessment. Reexamine [Table 4-2](#) now in light of the need statement. The links among problem, needs, goals and objectives, process, and outcome have been clearly illustrated. Each step of SOTP emerges from and is anchored in the previous step. Moreover, systematic thinking and action provide the specificity and credible evidence supporting the extent to which the intervention resolved the part of the problem that was identified as falling within the OT domain.

Review Questions

1. List three reasons why OT practitioners need to use SOTP to demonstrate the efficacy of OT to external audiences.
2. Name and describe each of the steps of SOTP.
3. Compare the steps of SOTP to the steps of the OT process.
4. Using a potential OT client as a case study, select a problem and develop a problem map.
5. Pose strategies to ascertain the need based on your problem statement.
6. Identify the need for your client based on your problem statement.
7. What is the difference between a goal and an objective, and what is their relationship?
8. How do goals and objectives relate to need?
9. How do goals and objectives relate to a problem?
10. Identify goals for your client.
11. What are the two types of objectives described in this chapter, and what are the differences between them?
12. Based on your goals for your client, identify at least two process objectives and two outcome objectives.

■ Box 4-2

Goals, Objectives, Evidence, and Success Criteria

Goal No. 1: Jane Will Improve Her Promptness to Be Able to Get to Work on Time (Performance) and to Her Satisfaction

1. **(P)** Jane will be supplied with catalogues and assistive devices from which to select those that she thinks will be most useful for her to achieve the goal.
Criterion for success: completion of activity
Evidence: notes of each session documenting progress toward goal
2. **(P)** Given a variety of assistive devices (e.g., alarm watches, paging devices, and clocks), Jane will choose a device to use as an external cue provider for promptness.
Criterion for success: selection of device
Evidence: notes of each session documenting progress toward goal
3. **(P)** Jane will select one activity at home for which she needs an external promptness cue.
Criterion for success: selection of activity
Evidence: notes of each session documenting progress toward goal
4. **(P)** With assistance from the OT, Jane and her husband will configure the device to cue Jane to attend to this daily event.
Criterion for success: demonstration that Jane and her husband have completed the objective
Evidence: progress notes indicating mastery of task
5. **(P)** Jane's husband will monitor her promptness and provide feedback to Jane and the therapist regarding the effectiveness of the assistive device in meeting the goal.
Criterion for success: daily record of Jane's promptness supplied to her each evening after dinner
Evidence: husband's written time charts
6. **(O)** Jane will demonstrate that she can promptly attend to her schedule at home.
Criterion for success: daily record of Jane's promptness at home
Evidence: husband's written time charts
7. **(P)** Once Jane has demonstrated that she can promptly attend to her schedule at home, she will begin to use the promptness cue to arrive at work.
Criterion for success: daily record of Jane's use of cues
Evidence: client self-report
8. **(O)** Jane will regularly arrive at work on time.
Criterion for success: daily record of Jane's promptness at work
Evidence: client's documented arrival time
9. **(P)** Once Jane has demonstrated that she can arrive at work on time, the therapist will work with Jane at the work site so that she can use the device to attend promptly to her work schedule to her and her employer's satisfaction.
Criterion for success: OT will meet Jane at work daily for 1 week to support use of device
Evidence: OT notes
10. **(O)** Using the most effective strategy and devices, Jane will improve her promptness sufficient to work and sufficient for her satisfaction.
Criterion for success: significant improvement in Jane's promptness
Evidence: COPM score on this item, compared with COPM score on pretest on this item

13. Identify how you will know that your objectives have been met.
14. Chose at least two interventions to achieve the goals and objectives you have established in question 12.
15. Identify what questions you will ask and how you will answer them in reflexive intervention.
16. Discuss how you will use reflexive intervention and outcome assessment data to contribute to OT knowledge.

MARJORIE E. SCAFFA

■ Chapter Outline

Historical influences and considerations

Early history and symbolism
Development of a profession
Milestones in occupational therapy health promotion interventions
Lifestyle Redesign programs
International trends

Health promotion principles and practice

Models of health promotion practice
Transtheoretical model
PRECEDE-PROCEED model
Occupational therapy involvement in health promotion and prevention

Health promotion and occupational participation
Secondary conditions and people with disabilities
Evaluation: emphasizing the promotion of health and well-being

Intervention

Summary

■ Key Terms

Moral treatment	PRECEDE-PROCEED model
Occupational justice	Disability prevention
Health promotion	Wellness
Health protection	Client-centered care
Prevention	Empowerment
Primary prevention	Enablement
Secondary prevention	Expert-centered
Tertiary prevention	Secondary conditions
Risk factors	Quality of life
Transtheoretical model	

■ Learning Objectives *After studying this chapter, the student or practitioner will be able to do the following:*

1. Discuss historical influences on occupational therapy's role in health promotion and wellness.
2. Define key health promotion and prevention concepts and terminology.
3. Describe the impact of Healthy People 2010 and the potential impact of Healthy People 2020 on occupational therapy practice.
4. Identify strategies for integrating health promotion into physical disability practice.
5. Develop a holistic, client- and occupation-centered health promotion perspective for physical disability practice.

“The American Occupational Therapy Association (AOTA) supports and promotes involvement of occupational therapists and occupational therapy assistants in the development and provision of health promotion and disease or disability prevention programs and services” (p. 694).⁶¹

AOTA, in its official statement on health promotion and prevention, describes three important roles for the profession:

to promote healthy lifestyles; to emphasize occupation as an essential element of health promotion strategies; and to provide interventions, not only with individuals but also with populations. It is important that occupational therapy practitioners promote a healthy lifestyle for all individuals and their families, including people with physical, mental, or cognitive impairments (p. 696).⁶¹

Threaded Case Study Jean, Part 1

Jean is a 49-year-old with three grown children, two of whom live away from home. The one living at home has a 2-year-old child. She has been married for 27 years. Jean developed gestational diabetes with her first-born child and has been insulin dependent for most of her married life. Jean is knowledgeable about diet, the need for exercise and activity, and insulin regulation. She is active in her community, works part-time to supplement her husband's income, and enjoys bowling, playing cards with friends every Friday night, crocheting, and maintaining her home.

Jean developed symptoms later confirmed to be a minor stroke. She lost sensation in her fingertips and in both lower extremities. As a result, she developed altered dynamic balance and grasp in both hands. She has coped with beginning glaucoma and diabetic neuropathies for several years. She has had a weakened cardiac status secondary to her diabetes despite her being active much of her life. Jean is overweight and has smoked a pack of cigarettes per day since she was 18 years old. Her husband also smokes regularly.

Critical Thinking Questions

1. How would you evaluate this client from a health promotion perspective?
2. In addition to standard occupational therapy services, what health promotion interventions might you use with this client and/or her family?

The value a society places on the health and welfare of its people can be measured by its level of commitment to policies and funding for healthcare. The wisdom of a society also can be measured by its commitment to prevention and health promotion. This chapter begins with a description of how the profession of occupational therapy has been involved in health promotion and prevention activities as well as with policy development. A new direction, which may come to be identified as a historical shift back to occupational therapy's concern with societal level problems, is also described.

This historical overview is followed by a review of health promotion principles and a description of health promotion-focused evaluation and intervention for individuals with physical disabilities. A case study helps readers to integrate the principles and practice of health promotion and prevention for people with physical disabilities and impairments.

Historical Influences and Considerations

Early History and Symbolism

Humans have long appreciated the health-promoting and healing qualities of engagement in occupation.^{49,52} History and anthropology,¹⁹ as well as archeology,⁸² provide rich examples of how people through time from cultures around the world have used occupations not only for survival but also as a means of healing and expressing identity and spirituality.^{9,20,82} In the United States, petroglyphs (cliff carvings) are as important to the living as those who fabricated them in the past, as Herman Agoyoyo, All-Indian Pueblo Council chairman (1988) has pointed out:

To us, these petroglyphs are not the remnants of some long lost civilization that has been dead for many years ... they are part of our living culture. What is stored in the petroglyphs is not written in any book or to be found in any library. We need to return to them to remind us of who we are and where we came from, and to teach our sons and daughters of it.⁷⁶

This pictorial evidence often depicts the human engagement in hunting or other subsistence activities through the use of symbols representing the human hand or animals.^{24,76} When living conditions allowed time for occupations other than for subsistence (i.e., activities of daily living and instrumental activities of daily living), humans turned their energy to identify these very occupations and the animals they shared their world with through symbols and artwork. These symbols convey feelings, identity, beliefs, and knowledge of these important occupations. Humans currently use symbols, often subconsciously, for these same purposes.²¹ The production of petroglyphs is early evidence of the importance of symbols and their influence on health. Through these symbols, early humans could communicate their essence to future generations and demonstrate that “through the use of his hands, as they are energized by mind and will, [man] can influence the state of his own health” (p. 2).⁵¹

The meanings or relevance of specific symbols can change through time in a society or within an individual. The symbolism of a handprint made during the Paleolithic period on the wall of the Cave of Chauvet-Pont-d'Arc²⁴ could carry both similar and different symbolism than that of a handprint of a small child to a parent of today. For individuals with disabilities, the familiar stick person in a

FIGURE 5-1 International symbol for access.

wheelchair symbol used to denote accessibility might have held little or no meaning prior to sustaining a physical disability. However, after an individual is diagnosed with or sustains a physical disability, this symbol (Figure 5-1), the International Symbol for Access (ISA), may take on new meaning and relevance for both that person and his or her family.

Development of a Profession

Many descriptions of the development of occupational therapy as a profession either start with or include a discussion of moral treatment.^{33,49,50,54} Moral treatment was defined as a “humane approach to the insane” that included occupation-based intervention that emphasized self-discipline, hard work, and learning self-control while developing “good habits.”⁸² (Chapter 2 provides a rich description of this time period and those who influenced the practice of occupational therapy with people with disabilities in the United States.) The values and beliefs of the founders of occupational therapy in the United States were consistent with and influenced by the values and beliefs of the mental hygiene movement, the arts and crafts movement, the settlement house movement, and the actions of other social activists and reformers in the United States at that time.^{10,35} These idealistic individuals and groups influenced the social injustice of their time. The backgrounds and contributions of the founders of occupational therapy in the United States are well documented.^{7,10,33,37,49,50,62} Therefore, the rest of this discussion focuses on (1) a summary of key events for involvement in health promotion and policy development in the United States and (2) recent international developments that may influence practice in the United States in the coming decades.

Milestones in Occupational Therapy Health Promotion Interventions

Leaders within the field of occupational therapy have been encouraging the profession’s increased attention to health promotion for many decades. As early as the 1960s, leaders^{12,77,78,80,81} articulated their vision of the role of occupational therapy in prevention and health promotion. Themes included (1) concerns of emphasis on cure or the saving of life versus the provision of services to maximize the quality of a saved life or the prevention of the illness or injury, (2) the match of occupational therapy values and principles with those of public health, (3) the untapped potential and responsibility for occupational therapy to contribute to the well-being of society, (4) the need to build and redefine the knowledge base of the profession, and (5) the responsibility to conduct research to determine effectiveness of community-based health promotion and prevention initiatives. Finn continued to encourage this involvement through an Eleanor Clarke Slagle Lecture²⁰ and subsequent work.^{22,23}

Through the years the AOTA has developed a series of statements and employed other means to focus attention on health promotion. In 1979, “Role of the Occupational Therapist in the Promotion of Health and the Prevention of Disabilities,” the first official document related to health promotion and prevention, was published.¹ This document has been revised and republished three times since then: in 1989,² 2001,¹¹ and most recently 2008.⁶¹ In 1986, the AOTA supported this role by devoting an entire issue of its journal, the *American Journal of Occupational Therapy (AJOT)*, to health promotion.⁷⁹ In 1992, an article on the history of occupational therapy’s role in preventive health appeared in the special 75th anniversary issue of the *AJOT*.⁵²

Besides encouraging occupational therapy’s role in health promotion within the profession, the AOTA has also promoted it to external audiences. The AOTA was a participant in the Healthy People 2000 Consortium.⁴ The consortium, together with 22 expert groups and numerous state and national governmental agencies and services, worked cooperatively to set the nation’s health agenda for the next decade.⁷³ Both this document and its current version, Healthy People 2010,⁷⁴ include targeted health goals for individuals with physical disabilities. Healthy People 2020⁷⁵ was released in 2010 identifying the goals for the next decade. A review of the current version at <http://healthypeople.gov> can assist occupational therapists in the development of new intervention strategies to address the documented unmet health needs of U.S. citizens, both with and without disabilities. In 2007 the AOTA selected six focus areas for the profession to emphasize in the decade leading to its centennial in 2017. Health and wellness is one of these six areas, the others include children and youth; productive aging; mental health; work and industry; rehabilitation, disability, and participation.⁵

Lifestyle Redesign Programs

The development of the Lifestyle Redesign programs by faculty at the University of Southern California (USC) Department of Occupational Science and Occupational Therapy is a significant event in health promotion occupational therapy practice. The outcome of the first of these programs for well elderly was published in a landmark article in the *Journal of the American Medical Association*.¹⁶ The intervention protocol that evolved for the Well Elderly Study was eventually named “Lifestyle Redesign.”³⁹ Results of this Lifestyle Redesign program indicated that “preventive occupational therapy greatly enhances the health and quality of life of independent-living adults” (p. xi).³⁹ Other Lifestyle Redesign programs have since been developed, for individuals both with and without disabilities. These include Lifestyle Redesign Weight Management Program, Lifestyle Redesign Pain Management, Lifestyle Redesign for the College Student, and Lifestyle Redesign for Student Veterans.⁷² The USC Faculty practice also has designed an interdisciplinary program with physical therapy for individuals living with multiple sclerosis (MS), entitled Optimal Living with MS.⁷²

International Trends

An international discussion started by Wilcock and Townsend has shaped the future of occupational therapy’s involvement in health promotion and prevention worldwide. Wilcock and Townsend called attention to the potential for occupational therapists and occupational therapy assistants to combat social and occupational injustice.^{68,82,83} The idea of occupational justice first emerged in Australia and Canada. Occupational justice is “the promotion of social and economic change to increase individual, community, and political awareness, resources, and equitable opportunities for diverse occupational opportunities which enable people to meet their potential and experience well-being” (p. 257).⁸² The World Federation of Occupational Therapists also is active in the call for the profession’s involvement in promoting occupational justice by encouraging occupational therapists’ contributions to the eradication of occupational deprivation.⁶⁴ The discussion is slowly emerging in the United States.^{6,53,58,71}

As occupational therapy practitioners further gain working knowledge of the political process, they can advocate for both the prevention of disability as well as the promotion of health and prevention of secondary conditions for individuals with disabilities who have been marginalized. In preparation for this advocacy, occupational therapy practitioners should familiarize themselves with the goals, especially “Goal 2: Eliminate Health Disparities” (p. 11), and other data available in Healthy People 2010⁷⁴ as well as Healthy People 2020⁷⁵ concerning reducing disparities and improving quality of life for individuals with disabilities.

One possible action occupational therapists and occupational therapy assistants can take is increasing their awareness of current history-making efforts that can be joined and supported. The independent living movement, which is working to combat these disparities and social injustice for individuals with disabilities, is one such example. However, if an occupational therapy practitioner singularly embraces the rehabilitation paradigm, he or she may not feel comfortable with either the principles of the independent living movement or its political agenda. Integrating a proactive approach to health that includes health promotion, wellness, and rehabilitation can significantly impact the quality of life of people with disabilities and their loved ones.^{44,46}

The rehabilitation paradigm identifies the problem with disability as the actual physical or mental impairment, whereas the independent living paradigm identifies the problem as the dependence on professionals and others. Under the rehabilitation paradigm, the person in control of service is the person with a disability. In the rehabilitation model, the desired outcome of service delivery is maximum physical or mental functioning (or, as in vocational rehabilitation, gainful employment). Desired outcomes in independent living are tied to having control over one’s daily life. Control does not necessarily mean having the physical or mental capacity to perform everyday tasks for one’s self. For some disability groups, complete control may not be possible, but the independent living movement continues to work toward complete consumer control wherever and whenever possible.⁶³

An important milestone in international efforts to ensure these and other equal rights for individuals with disabilities was the adoption in 2006 of the United Nations Convention on the Rights of Person with Disabilities. The United States did not sign this convention until 2009, at which time 142 other countries had signed.^{69,70}

Occupational therapists and occupational therapy assistants need to look beyond the immediate rehabilitation goals to be truly client-centered in their practice.⁶⁸ Time also must be found to advocate for equal access and rights for all people, marginalized or not, with or without physical disabilities. In a sense, this discussion has come full circle, with the opportunity to emulate the original founders of the profession by becoming social activists.

Ethical Considerations

The profession of occupational therapy has the potential to be able to conduct an assessment of societal issues that impact the daily occupational rights and function of marginalized individuals, groups, and communities. Through education, political advocacy, and activism, occupational therapists can draw attention to the inequities that exist.

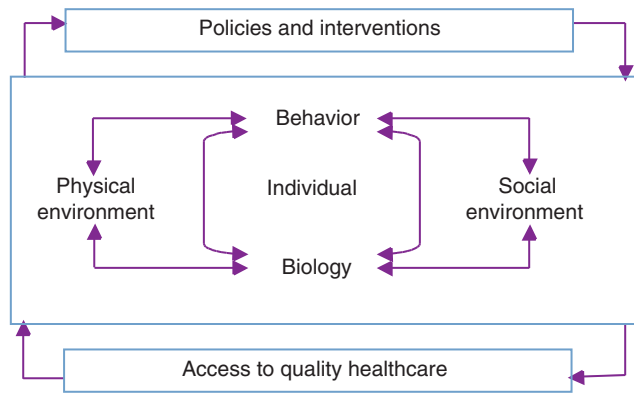

FIGURE 5-2 Determinants of health.

(From U.S. Department of Health and Human Services: *Healthy people 2010: understanding and improving health*, ed 2, Washington, DC, 2000, U.S. Government Printing Office.)

Health Promotion Principles and Practice

Health is a constant interplay of a variety of factors and therefore is not static but always changing. Health and illness/disease, like functional ability/disability, are not mutually exclusive categories but rather a finely graded continuum.¹⁸ Important determinants of health status include individual biology and behavior, social and physical environments, policies and interventions, and access to health-care (Figure 5-2).⁷⁴ Examining birth and death rates, incidence and prevalence of disease, injury and disability, use of health-care services, life expectancy, quality of life, and other factors can evaluate the health status of a population. Leading health indicators were established during the development of Healthy People 2010 in an effort to focus the national health promotion agenda. The leading health indicators that served as the foundation for the strategic planning process include “physical activity, overweight and obesity, tobacco use, substance abuse, responsible sexual behavior, mental health, injury and violence, environmental quality, immunization and access to health care” (p. 24).⁷⁴

Health promotion is defined by the World Health Organization (WHO) as

the process of enabling people to increase control over, and to improve, their health. To reach a state of complete physical mental and social wellbeing, an individual or group must be able to identify and to realize aspirations, to satisfy needs, and to change or cope with the environment. Health is, therefore, seen as a resource for everyday life, not the objective of living (¶ 1).⁸⁴

Health promotion encompasses both health protection and prevention of disease and disability. Health protection strategies are targeted at populations and include control of infectious diseases, immunizations, protection from occupational hazards, and governmental standards for the regulation of clean air and water, sanitation, and food and drug

safety among other things.¹⁸ Prevention refers to “anticipatory action taken to reduce the possibility of an event or condition from occurring or developing, or to minimize the damage that may result from the event or condition if it does occur” (p. 81).⁴² Prevention strategies can be categorized on three levels: primary, secondary, and tertiary.

Primary prevention focuses on healthy individuals in order to decrease vulnerability or susceptibility to disease, disability, or dysfunction. Primary prevention strategies include good nutrition, regular physical activity, adequate housing, recreation and working conditions, genetic screening, periodic physical examinations, and seatbelt laws. Secondary prevention focuses on persons at risk or in the early stages of disease with the goal of arresting the disease progression and preventing complications and disability. Secondary prevention strategies include early detection and intervention, as well as screening for chronic diseases such as cancer, coronary artery disease, and diabetes. Tertiary prevention focuses on persons with disease or disability and attempts to prevent further complications, minimize the effects of the condition, and promote social opportunity. Tertiary prevention strategies include rehabilitation services and the removal of architectural and attitudinal barriers to social participation.^{18,28,59}

Health promotion and prevention approaches attempt to reduce risk factors and enhance protective or resiliency factors. Risk factors are human characteristics or behaviors, circumstances, or conditions that increase the likelihood or predispose an individual or community to manifest certain health problems. Risk factors include not only physical conditions such as hypertension and behaviors such as smoking but also social, economic, and environmental conditions such as poverty, homelessness, exposure to radiation, and pollution.^{18,59} Research indicates that “it is usually the accumulation of risk rather than the presence of any single risk factor that affects outcomes, and that multiple risks usually have multiplicative rather than merely additive effects” (p. 512).¹⁷ Protective or resiliency factors are human characteristics or behaviors, circumstances, or conditions that decrease susceptibility or increase an individual’s or community’s resistance to illness, disability, dysfunction, or injury. Protective factors include not only an individual’s genetic profile, personality, and health behaviors, but also peer and family relationships, social norms, and social support.^{17,59}

Models of Health Promotion Practice

In the health promotion field there are a number of individual, interpersonal, and community models and theories of health behavior change.^{55,56} Two models will be presented here briefly in order to help the practitioner better conceptualize health promotion interventions. One model, the transtheoretical model, also known as the stages of change model, was designed to facilitate individual health behavior change and is therefore extremely relevant to occupational

therapy practitioners. The second model, PRECEDE-PROCEED, is an approach to planning that facilitates the design, implementation, and evaluation of health promotion interventions.²⁵

Transtheoretical Model

The transtheoretical model (TTM) is based on the premise that change occurs in stages. The model consists of six stages: precontemplation, contemplation, preparation, action, maintenance, and termination. Precontemplation is the stage in which the person has no intention of taking action to modify health behaviors. This may be due to lack of knowledge, previous failed attempts at changing health behavior, or simply a lack of motivation. The contemplation stage is characterized by intention to modify behaviors within the next 6 months, but with some ambivalence regarding the costs and benefits of doing so. The preparation stage is an indication that the person is ready to take action in the very near future (30 days or less) and has demonstrated some initiative to plan the change strategies such as reading a self-help book, joining a health club, or talking to a physician. Action refers to specific overt manifestations of lifestyle modification. The duration of this stage is a minimum of 6 months. After 6 months of sustained health behavior change, a person is considered to be in the maintenance stage. The goal of this stage is to prevent relapse into previous unhealthy behaviors. Termination is the stage at which a person is no longer tempted and has a sense of self-efficacy that permits the person to maintain healthy behaviors even in stressful, high-risk situations. True termination may be unrealistic for most behavioral changes, and lifelong maintenance may be the appropriate goal for the majority of people.⁴⁸

According to the TTM, change occurs through “covert and overt activities that people use to progress through the stages” (p. 103).⁴⁸ These activities or processes of change include consciousness raising, dramatic relief, self-reevaluation, environmental reevaluation, self-liberation, helping relationships, counter-conditioning, contingency or reinforcement management, stimulus control, and social liberation. The developers of the TTM discovered that each of these processes is more or less effective during different stages of change. For example, consciousness raising is critical in the precontemplation stage in order for the person to progress to the contemplation stage. Contingency management and stimulus control strategies are most useful in the maintenance stage to prevent relapse.⁴⁸

PRECEDE-PROCEED Model

The PRECEDE-PROCEED model is used for planning interventions and consists of nine steps (Box 5-1). The PRECEDE portion of the model is based on the assumption that health behaviors are the result of a complex interaction of multiple factors.^{26,27} In the PRECEDE framework, these factors are identified and specific objectives are developed for a population. The PROCEED portion of the

Box 5-1

Steps of the PRECEDE-PROCEED Model

- Step 1: Social Assessment
- Step 2: Epidemiologic Assessment
- Step 3: Behavioral and Environmental Assessment
- Step 4: Educational and Ecological Assessment
- Step 5: Administrative and Policy Assessment
- Step 6: Implementation
- Step 7: Process Evaluation
- Step 8: Impact Evaluation
- Step 9: Outcome evaluation

From Green LW, Kreuter MW: *Health promotion planning: an educational and ecological approach*, ed 3, Mountain View, CA, 1999, Mayfield.

model consists of policy development, intervention implementation, and evaluation. The first five steps represent a comprehensive needs assessment that evaluates a number of social, epidemiologic, behavioral, environmental, educational, ecologic, administrative, and policy issues that might affect the development, implementation, and ultimate success of a health promotion intervention. After all of these factors are considered, the intervention is developed and implemented. The final three steps represent a comprehensive evaluation of the intervention, including process, impact, and outcome measures.²⁷

PRECEDE-PROCEED has been used to plan, implement, and evaluate health promotion interventions in school, work, healthcare, and community settings. It has been used to address a number of health issues including smoking cessation, HIV prevention, seat belt use, driving under the influence of alcohol, nutrition, exercise and fitness, blood pressure control, stress management,²⁷ as well as depression and pain among individuals with rheumatoid arthritis.⁴⁰ Typically, interventions designed using the PRECEDE-PROCEED model address multiple risk factors and health behaviors and use multiple intervention strategies.

Occupational Therapy Involvement in Health Promotion and Prevention

The Healthy People 2010 goal in the area of disability and secondary conditions is to “promote the health of people with disabilities, prevent secondary conditions, and eliminate disparities between people with and without disabilities in the U.S. population” (p. 6-3).⁷⁴ Several objectives in this area are appropriate for occupational therapy intervention (see Box 5-1). The objectives in Healthy People 2010 address both individuals with disabilities and the environments in which they function, as it is recognized that disability is the result of the interaction between individual limitations and barriers in the environment.⁷⁴

The Occupational Therapy Practice Framework: Domain and Process³ describes health promotion and disability

prevention as appropriate intervention approaches for the profession. The WHO approach to defining health promotion, which was cited early in this chapter, appears in the glossary of the framework together with this definition: “[C]reating the conditions necessary for health at individual, structural, social, and environmental levels through an understanding of the determinants of health: peace, shelter, education, food, income, a stable ecosystem, sustainable resources, social justice, and equity” (as quoted from Trentham and Cockburn, 2005, p. 441, and as cited in AOTA³, p. 671).

Disability prevention is defined as

an intervention approach designed to address clients with or without a disability who are at risk for occupational performance problems. This approach is designed to prevent the occurrence or evolution of barriers to performance in context. Interventions may be directed at client, context, or activity variables. (adapted from Dunn et al., 1998, p. 534, and as cited in AOTA, p. 659)³

Wellness is the outcome of the efforts of an individual or family. Health promotion programming can assist individuals and families reach a state of wellness in their lives.⁶⁰ Wellness is defined in the framework as “an active process through which individuals become aware of and make choices toward a more successful existence” (Hettler, 1984, p. 1117, and as cited in AOTA, p. 676).³ Occupational therapy practitioners facilitate wellness through holistic and client-centered health promotion practice.

Occupational therapy involvement in health promotion and prevention can assume a variety of forms. For example, primary prevention could include providing education to workers regarding their personal risk factors for injury on the job (such as poor body mechanics) or altering the environment to reduce the incidence of workplace accidents. Secondary prevention strategies in occupational therapy practice include joint protection, energy conservation, and work simplification techniques. Fall prevention programs and home safety evaluations for frail elderly clients are other examples of secondary prevention. Occupational therapists and occupational therapy assistants are experts in tertiary prevention, as they provide services to maximize function and minimize barriers to occupational performance.^{28,59}

Occupational therapists and occupational therapy assistants who develop occupation-based health promotion and prevention programs should be cognizant of the literature in public health and use existing evidence on best practice. The American Public Health Association (APHA) developed standards for the design and implementation of health promotion programs that can guide occupational therapy health promotion efforts. These five principles include the following:³⁸

- Addressing multiple risk factors that are measurable and clearly defined

- Focusing on the identified and expressed needs and preferences of the client or target population
- Including evidence-based interventions with demonstrated effectiveness
- Using client and community strengths and available resources
- Designing programs that can be sustained and evaluated

Within the context of being a person with a disabling condition, health and well-being issues are often minimized as people with disabilities are medicalized, rehabilitated, and looked on as in need of long-term care financing.⁷⁴

Four main misconceptions emerge from this contextual approach: (1) all people with disabilities automatically have poor health, (2) public health should focus only on preventing disabling conditions, (3) a standard definition of disability or people with disabilities is not needed for public health purposes, and (4) the environment plays no role in the disabling process⁷⁴ (p. 6-3).

A health promotion framework is needed that focuses on client needs (and those of caregivers) and one that explores the holistic needs of people with disabilities and their caregivers. The health and wellness approach to care would still include the functional needs of people, but will help occupational therapy practitioners to focus on health needs, issues of well-being, quality of life,⁴⁶ and participation in society. This approach will also help the profession to examine more closely the role of occupational therapy in the prevention of secondary disabilities in order to promote healthy and meaningful participation.

Health Promotion and Occupational Participation

Health promotion interventions assist in enabling people with disabilities to more fully engage and participate in society. According to Hills,²⁹ there are three “pillars and related assumptions” of health promotion: (1) the primacy of people, (2) empowerment, and (3) enablement.

All three of these concepts, especially the primacy of people, focus on what the profession of occupational therapy calls client-centered care. The Canadian Association of Occupational Therapy (CAOT) defines client-centered practice as the following:¹³

Collaborative approaches aimed at enabling occupation with clients who may be individuals, groups, agencies, governments, corporations or others. Occupational therapists demonstrate respect for clients, involve clients in decision making, advocate with and for clients in meeting clients’ needs, and otherwise recognize clients’ experience and knowledge. (p. 49)

It is this client-centered approach that is health promoting for individuals with physical disabilities. The respect for

and involvement in decision making, particularly in occupational participation, is a foundational similarity in both health promotion and occupational therapy. Occupational therapists facilitate meaning and assist people in seeing a hopeful future through occupational engagement and enablement of participation. This focus will help foster optimal health and wellness for people with disabilities.

Empowerment speaks to the development of autonomy and self-control. Occupational therapists are skilled at creating contexts and occupation-based interventions that support and facilitate the feeling of being empowered. “To increase control over and to improve one’s health, one must not only be empowered to do so but also able to do so. To be able, one must possess the requisite skills, resources and knowledge” (p. 232).²⁹ People with impairments and disabilities and those at risk for impairment and disability can be knowledgeable about the need to change health behaviors that undermine the promotion of healthy living (e.g., smoking); however, they may be lacking skills and resources to achieve optimal well-being. “The fundamental assumption underlying the notion of enablement is that people have capacity to identify their own needs, to solve their own problems and to generally know what is best for them” (p. 232).²⁹

To effectively promote health and well-being, occupational therapists should embrace the belief that people are capable of identifying needs and are able to problem-solve life challenges. Implementing client-centered approaches versus expert-centered approaches (those approaches that come from therapists without inclusion of clients or their caregivers) will empower people with disabilities to view themselves as valued and contributing members of society.

Powers provided a glimpse into the lived experiences of people with disabilities and their perceptions of health and well-being.⁴⁷ She believes there is need to develop more models of health and wellness that specifically address the needs of people with disabilities. However, the models currently used, some of which are discussed earlier, do enhance the knowledge of health professionals regarding people with disabilities. Health and illness can and do coexist on a daily basis for people with physical impairments and disabilities:

OT Practice Note

It behooves occupational therapists and occupational therapy assistants to begin to make that paradigm shift and transition from defining oneself as a rehabilitation specialist to a specialist in occupation, health promotion, and well-being using occupation to facilitate healthy living. Through listening to the narratives of people with disabilities and engaging in client-centered evaluation and interventions, occupational therapists and occupational therapy assistants can assist people with disabilities and chronic illnesses to maximize QOL and participation in society.³⁹

[L]iving healthy and well is not something new for people with disabilities. Currently, a stereotype exists that suggests people with disabilities are “sick” or are “perpetual patients” who cannot be considered “healthy” or “well.” However, for years people with disabilities have used strategies to maintain health and wellness, created supportive relationships, and accessed needed resources from various service systems. It is from these resourceful people that health professionals need to be willing to continue learning about issues related to health, wellness and long-term disability.⁴⁷ (p. 73)

Secondary Conditions and People with Disabilities

Secondary conditions can be defined as “those physical, medical, cognitive, emotional, or psychosocial consequences to which persons with disabilities are more susceptible by virtue of an underlying impairment, including adverse outcomes in health, wellness, participation and quality of life” (p. 162).³⁰ The term *secondary conditions* expanded the term *comorbidity*, which is a term often used in medical settings.

However, the term *secondary condition* adds three dimensions not fully captured by the term *comorbidity*. It includes (1) nonmedical events (e.g., isolation), (2) conditions that affect the general population (e.g., obesity, with higher prevalence among people with disabilities), and (3) problems that arise any time during the life span (e.g., inaccessible mammography). Children and adults with disabilities can experience secondary conditions any time during their life span.¹⁴

Occupational therapists can aid in the prevention of secondary conditions through increasing client awareness and patient education about health, healthy habits and routines, and strategies to offset increasing secondary conditions or other disability. Healthy People 2010 set clear objectives for the reduction of secondary conditions (Box 5-2).

In view of the increased rates of disability among youth, it is particularly important to target activities and services that address all aspects of health and well-being, including promoting health, preventing secondary conditions, and removing environmental barriers, as well as providing access to medical care. For an older person with a disability, it is important to target worsening coexisting conditions that may intensify and thus threaten general well-being. For example, declining vision combined with declining hearing can greatly impair mobility, nutrition, and fitness, conditions that may intensify and thus threaten general well-being⁷⁴ (pp. 6-4, 6-5).

Hough believes that a paradigm shift from disability prevention to prevention of secondary conditions is needed.³⁰ After the inability to prevent primary disability, “it is within the environment that the negative effects of secondary conditions could be ameliorated and even

■ Box 5-2

Healthy People 2010 Disability and Secondary Conditions Objectives

- Reduce the proportion of children and adolescents with disabilities who are reported to be sad, unhappy, or depressed.
- Reduce the proportion of adults with disabilities who report feelings such as sadness, unhappiness, or depression that prevent them from being active.
- Increase the proportion of adults with disabilities who participate in social activities.
- Increase the proportion of adults with disabilities who report sufficient emotional support.
- Increase the proportion of adults with disabilities who report satisfaction with life.
- Reduce the number of people with disabilities in congregate care facilities, consistent with permanency planning principles.
- Eliminate disparities in employment rates between working-aged adults with and without disabilities.
- Increase the proportion of children and youth with disabilities who spend at least 80% of their time in regular education programs.
- Increase the proportion of health and wellness treatment programs and facilities that provide full access for people with disabilities.
- Reduce the proportion of people with disabilities who report not having the assistive devices and technology that they need.
- Reduce the proportion of people with disabilities who report environmental barriers to participation in home, school, work, or community activities.

Adapted from U.S. Department of Health and Human Services: *Healthy people 2010: understanding and improving health*, ed 2, Washington, DC, 2000, U.S. Government Printing Office.

prevented” (pp. 187-188). Public health agencies often focus efforts toward primary prevention, and secondary conditions need to be of equal concern. The emphasis on policy change and education of health professionals on health promotion for people with disabilities can help foster interventions toward self-management of one’s disability.

Stuifbergen, Gordon, and Clark emphasized the need for health practitioners to integrate health promotion strategies in neurorehabilitation for people with stroke.⁶⁵ Krahn emphasized the need to encourage self-responsibility for health to promote health and well-being while living with a disability,³⁴ whereas Rimmer⁵⁷ has viewed health promotion as a means to maintain functional independence by preventing secondary conditions. “People with disabilities have increased health concerns and susceptibility to secondary conditions. Having a long-term condition increases the need for health promotion that can be medical, physical, social, emotional, or societal” (p. 6-4).⁷⁴

The development of secondary conditions and occupational impairments can be directly related to one’s mental health. Psychosocial aspects of physical disabilities are as important to identify and help ameliorate as the physical barriers to occupational participation.

People who have activity limitations report having had more days of pain, depression, anxiety, and sleeplessness and fewer days of vitality during the previous month than people not reporting activity limitations. Increased emotional distress, however, does not arise directly from the person’s limitations. The distress is likely to stem from encounters with environmental barriers that reduce the individual’s ability to participate in life activities and that undermine physical and emotional health⁷⁴ (pp. 6-4, 6-5).

Exploration of a person’s disability, in the context of one’s life situations, and the physical and emotional impacts of that disability on participation exemplifies occupational

therapy practice committed to optimizing quality of life (QOL). QOL is an outcome of occupational therapy as defined by the framework. QOL is “a person’s dynamic appraisal of his or her life satisfactions (perceptions of progress toward one’s goals), self-concept (the composite of beliefs and feelings about oneself), health and functioning (including health status, self-care capabilities, role competence), and socioeconomic factors (e.g., vocation, education, income)”³ (p. 628).

Stuifbergen and Rogers interviewed 20 individuals with MS who shared their stories about health promotion, QOL, and factors that affected these areas of health.⁶⁶ They identified six life domains related to QOL, including family (most frequently identified domain), functioning to maintain independence, spirituality, work, socioeconomic security, and self-actualization. Six broad themes also emerged related to health-promoting behaviors. These included exercise or physical activity, nutritional strategies, lifestyle adjustment, maintaining a positive attitude, health responsibility behaviors, and seeking and receiving interpersonal support.⁴³ Occupational therapy practitioners play a key role in helping people actualize QOL through interventions that include these themes. Physical disability does not translate to being unable to participate and experience a good QOL. The paradigm shift to promoting health and wellness is necessary to optimize QOL.

Evaluation: Emphasizing the Promotion of Health and Well-Being

Evaluation of people with disabilities must include the life story or narrative of the person as elicited through careful occupational history taking. This occupational profile is coupled with physical, sensorimotor, social, psychological,

and emotional assessments to create a holistic view of the person. The most important element in evaluation is incorporating the client's perspectives of health and well-being, as well as his or her values, beliefs, and contexts of living experiences. Client-centered care promotes healthy views of living for the client and the family system, from the beginning of occupational therapy intervention through discharge.

The Pizzi Holistic Wellness Assessment (PHWA)⁴⁵ was created for adults and is a subjective, occupation-focused, and client-centered assessment tool. It measures, both qualitatively and quantitatively, self-perceptions of a person's health and wellness in eight different categories. It is an assessment that is not focused on the disability but instead emphasizes one's abilities and current levels of well-being. Collaboratively, the client and therapist work on strategies that the client identifies as health promoting for each area, as well as using the clinical reasoning of the therapist to problem-solve health issues related to occupational performance. A systems perspective was used during its development. Thus, it is a useful assessment and research tool for clients as well as caregivers of people with disabilities. For example, a caregiver may report additional burden achieving occupational balance of roles and occupations, as well as the caregiving responsibilities. The caregiver could benefit from occupational therapy intervention to address identified needs, based on responses from the PHWA. The assessment is available at www.michaelpizzi.com.

Table 5-1 shows a number of assessments from a variety of disciplines that may be helpful to occupational therapists as they consider how to enhance their health promotion interventions with people with disabilities.³¹ The purpose of this table is to encourage practitioners to seek resources outside of the discipline that may increase options to facilitate the end goal of enhanced participation in occupations.

Threaded Case Study Jean, Part 2

For Jean, the PHWA could be used to evaluate the following:

- Occupational habits, routines, and patterns that may be barriers to general health (e.g., smoking, eating habits).
- Balance in daily life activity and barriers to fuller participation in occupation.
- Stress and psychosocial areas that may exacerbate cardiac insufficiency, increase smoking and eating problems, and create insulin imbalance (use stress and depression scales to help assess these areas).
- Physical versus sedentary activity levels and reasons for these activity patterns.
- Risk factors for development of secondary conditions related to her physical function and past medical history.
- Contexts for occupation including the current support system. Caregiver assessment, especially level of support for Jean, can be crucial for health promotion programming.

Inclusion of a tool in this table should not be considered an endorsement of the tool. Readers are encouraged to critically examine assessment tools in terms of reliability, validity, sensitivity, and practicability, as well as possible training or certification required prior to use. Similar tables and lists of assessments that are more commonly used and known by occupational therapy practitioners exist that include assessments developed both within and external to the field.^{8,15} These compilations include numerous additional assessments, which along with other resources, should be reviewed and considered prior to an assessment being selected for a specific client or client group. Assessments, when chosen appropriately and used competently, can be an important tool in implementing client-centered care.^{36,41} Table 5-2 offers additional guidance and considerations for the selection of an assessment.⁶⁷

Intervention

For people with disabilities, health promotion interventions are designed to optimize health status. One focus of these interventions is to help prevent secondary conditions from occurring and thus help people with disabilities maintain a level of well-being that allows them to engage in meaningful life roles. The framework identifies six areas of focus for intervention: (1) areas of occupation, (2) performance skills, (3) performance patterns, (4) context(s) or physical environment, (5) activity demands, and (6) client factors.³ All these areas affect each other, and, in turn, affect occupational performance and participation.

Interventions to promote health and well-being are implemented with consideration of all these areas. Five approaches to intervention are listed in the framework. Although they all can relate to health promotion, the framework specifically links the “create, promote” approach (p. 657)³ to health promotion. Even though the framework indicates this approach “does not assume a disability is present” (p. 657),³ it can be used with people with occupational impairments and disability, as it is “designed to provide enriched contextual and activity experiences that will enhance performance for all persons in the natural contexts of life” (adapted from Dunn, McClain, Brown, & Youngstrom, 1998, p. 534, and cited in AOTA, p. 657).³

As stated earlier, a paradigm shift for therapists' therapeutic reasoning is needed to understand that health, wellness, and disability can be co-mingled and interventions to promote healthy living with a disability are vital for a person with disability. Although the intervention approach of create or promote is most closely related to health promotion, the other four approaches (i.e., establish/restore, maintain, modify, and prevent)³ are all related to the creation of healthy lifestyles and well-being. They also should be considered as potential approaches for the restoration and promotion of health for individuals with disabilities.

Often, such work is more successful when performed by a multidisciplinary team. An excellent example of a

multidisciplinary program that utilizes several approaches discussed above is the MS Care Center at New York University’s Langone Medical Center.³²

Summary

This chapter introduced readers to health promotion and wellness concepts within the context of physical disability practice. An introduction to the power of symbols, important concepts such as occupational justice, and principles and practice of health promotion help support best practice.

Although practitioners have long promoted optimal health for clients of all ages, there has been little discussion about theoretical foundations for evaluation and intervention in health promotion. The framework is a helpful guide to assist practitioners in bridging gaps in service delivery and integrating health promotion into everyday practice. Through the framework, AOTA emphasizes occupational engagement and participation in life as the means to health, wellness, and quality of life. Occupational therapy practitioners create and promote healthy living via careful attention to the physical, psychosocial, spiritual, social, and

Threaded Case Study | Jean, Part 3

The Jean case example illustrates how a health promotion approach for a person with disability can be implemented. In addition to standard occupational therapy services, a health promotion approach might be appropriate with this client or her family. Potential health promotion interventions are described next.

If Jean's occupational habits, routines, and patterns are maladaptive and are barriers to healthy living, then patient education around developing healthy habits (including how her habits can result in further medical complications) should be implemented.

An imbalance in occupations and occupational performance can contribute to the exacerbation of stress, cardiac issues, and affect insulin production. Increasing awareness of the need for balance in daily life, including balance of work, play, rest, sleep, and leisure, can assist Jean in creating a new structure for her occupational living and optimize her quality of life.

Stress, depression, and other psychosocial factors can exacerbate preexisting conditions and lead to inactivity, poor self-esteem, and eventually poorer health. Client-centered care that incorporates meaningful and interesting occupation relevant to the person in your care can help offset psychosocial conditions. Areas of concern could be feelings of worthlessness or ineffectiveness because one cannot occupationally engage in meaningful life activity. Jean may experience these issues because of her limited (and potentially limiting) medical condition. Exploring the impacts of stress, depression, and other factors on occupational performance and creating new occupational strategies for Jean can improve occupational performance and lead to Jean developing a future that includes

“preventive occupations”—in this case, preventing further or future depression and managing her stress.

After assessing activity levels, occupational interventions that promote a healthy heart, decrease smoking and overeating, and improve general mental and physical fitness are primary in Jean's case. Once Jean is aware of her abilities and develops a knowledge based on her real and perceived levels of activity, the occupational therapy practitioner can help her modify and adapt her lifestyle to incorporate activity that optimizes mental and physical health. It is important for Jean to optimize health for both present and future occupational performance in multiple contexts.

Interventions must include measures to prevent the development of secondary conditions. For example, Jean has developed the warning sign (transient ischemic attack [TIA]) of potential future stroke. Preventive occupations can include increasing walks outdoors by 5 minutes each week to reach a daily target of 30 minutes maximum, working with an occupational therapy practitioner to help decrease smoking and overeating habits, or developing a stress management program. These health promotion program ideas can be habituated in the acute care and home care settings and followed through by Jean and her loved ones.

Caregiver support is critical for implementing and following through with a health promotion program. In Jean's case, she requires strong support to help her recognize and prevent future health problems (e.g., reminders, environmental and verbal cues, ongoing education). She also will need support with smoking cessation, developing healthy eating (and cooking) habits, and increasing optimism for a healthy and bright future.

emotional abilities and challenges that support, or are barriers to, occupational performance. Holistic evaluation and goal planning utilizing a client-centered approach should include health promotion goals that are co-developed between the client and the practitioner.

Engagement in occupation to support participation in context is a key focus of the framework. A health promotion approach enhances awareness of barriers to health and wellness, and strategies are developed to optimize health, as well as prevent future health problems. Risk factors are

considered and interventions are implemented to support participation while creating a new lifestyle that is meaningful to the client. Client factors, although important to address to optimize occupational performance, are integrated into a top-down approach to care when providing a health promotion program. In the case example, Jean can engage in a physical activity program designed to improve her cardiac status while she develops strategies to control the pain and discomfort, which are the secondary complications of her diabetes, as she works to decrease or cease smoking. If Jean decreases or stops smoking, she also will have a positive impact on the overall health of her family, especially her grandchildren, by decreasing or removing the health risks of secondary smoke exposure.

As practitioners learn more about health promotion, prevention, and wellness, they will be better equipped to promote healthy living within the context of a person's lifestyle. Client-centered and occupation-centered care that includes health promotion and focuses on the whole person living with disability can be occupational therapy's unique contribution to humanity.

Review Questions

1. Consider the importance of symbols. Do you think the current international symbol for accessibility is inclusive of all individuals with physical disabilities? Why or why not? Sketch an alternative symbol.
2. Describe the historical relationship between social activism and occupational justice for individuals with disabilities.
3. Identify an objective from Healthy People 2020 to support a new health promotion program you want to develop for your client group.
4. Describe the determinants of health as identified in Healthy People 2020 and discuss how occupational therapy can address these determinants.
5. Identify the levels of prevention, and give examples of potential occupational therapy interventions at each level.
6. Choose a health behavior of interest, and describe the stages of change associated with that health behavior using the transtheoretical model.
7. Discuss how occupational therapists can facilitate resiliency for their clients with disabilities.
8. How would health promotion approaches fit within the Occupational Therapy Practice Framework?

Personal and Social Contexts of Disability: Implications for Occupational Therapists

6

SANDRA E. BURNETT*

■ Chapter Outline

Client-centered self-report

Personal context

Disability experience

Individual differences

Stage models of adjustment to disability

Stages of life and self-concept

Understanding individual experience

Social context

Social status and disability

Disability as a collective experience

Occupational therapy practice and the independent

living philosophy

Person-first language

Culture of disability

Design and disability

Interactional process: the person with a disability and the environment

International classification of functioning, disability, and health

Relationship between the OT and person with a disability

Therapist as an environmental factor

Therapeutic use of self

Client-centered practice: A shift from the medical to the social model

Life satisfaction and quality of life

Summary

■ Key Terms

Independent living movement

Devaluation

Medical model

Social model

Stigma

Stereotype

Liminality

Spread

Person-first language

■ Learning Objectives *After studying this chapter, the student or practitioner will be able to do the following:*

1. Describe the philosophy of the independent living movement and compare and contrast its view of the medical model and the social model of disability. Discuss implications of the philosophy of the independent living movement with occupational therapy practice.
2. Describe the personal context of the disability experience, noting the effect of individual differences, gender, type of disability, interests, beliefs, stage of life, and the usefulness of the stage models of disability adaptation.
3. Describe the social context of disability using the concepts of stigma, stereotypes, liminality, and spread. Discuss the effect on social context of person-first language, the culture of disability, and universal design principles.
4. Describe the ways the International Classification of Functioning, Disability, and Health (ICF) challenges mainstream ideas of health and disability.
5. Discuss various relationship issues between the occupational therapist and the person with a disability.

*Dr. Elizabeth J. Yerxa's personal encouragement and foundation work were essential to the creation of this revised chapter.

Threaded Case Study | Nancy, Part 1

I was never a beautiful woman, and for that reason I've spent most of my life (together with 95% of the female population of the United States) suffering from the shame of falling short of an unattainable standard. The ideal woman of my generation was ... perky, I think you'd say, rather than gorgeous. Blond hair pulled into a bouncing ponytail. Wide blue eyes, a turned-up nose with a maybe a scattering of golden freckles across it, a small mouth with full lips over straight white teeth. Her breasts were large but well harnessed high on her chest; her tiny waist flared to hips just wide enough to give the crinolines under her skirt a starting push. In terms of personality, she was outgoing, even bubbly, not pensive or mysterious. Her milieu was the front fender of a white Corvette convertible, surrounded by teasing crew-cuts, and dressed in black flats, a sissy blouse, and the letter sweater of the Corvette owner. Needless to say, she never missed a prom.

Ten years or so later, when I first noticed the symptoms that would be diagnosed as [multiple sclerosis], I was probably looking my best. Not beautiful still, but the ideal had shifted enough so that my flat chest and narrow hips gave me an elegantly attenuated shape, set off by a thick mass of long, straight, shining hair. I had terrific legs, long and shapely, revealed nearly to the pudendum by the fashionable miniskirts and hot pants I adopted with more enthusiasm than delicacy to taste. Not surprisingly, I suppose, during this time I involved myself in several torrid love affairs.

The beginning of MS wasn't too bad. The first symptom, besides the pernicious fatigue that had begun to devour me, was "foot drop," the inability to raise my left foot at the ankle. As a consequence, I'd started to limp, but I could still wear high heels, and a bit of a limp might seem more intriguing than repulsive. After a few months, when the doctor suggested a cane, a crippled friend gave me quite an elegant wood-and-silver one, which I carried with a fair amount of panache.

The real blow to my self-image came when I had to get a brace. As braces go, it's not bad: lightweight plastic molded to my foot and leg, fitting down into an ordinary shoe, and secured around my calf by a Velcro strap. It reduces my limp and, more importantly, the danger of tripping and falling. But it meant the end of high heels. And it's ugly. Not as ugly as I think it is, I gather, but still pretty ugly. It signified to me, and perhaps still does, the permanence and irreversibility of my condition. The brace makes my MS concrete and forces me to wear it on the outside. As soon as I strapped the brace on, I climbed into trousers and stayed there (though not in the same trousers, of course). The idea of going around with my bare brace hanging out seemed almost as indecent as exposing my

breasts. Not until 1984, soon after I won a Western States Book Award for poetry, did I put on a skirt short enough to reveal my plasticized leg. The connection between winning a writing award and baring my brace is not merely fortuitous; being affirmed as a writer did really embolden me. Since then, I've grown so accustomed to wearing skirts that I don't think about my brace any more than I think about my cane. I've incorporated them, I suppose: made them, in their necessity, insensate but fundamental parts of my body.

Meanwhile, I had to adjust to the most outward and visible sign of all, a three-wheeled electric scooter called an Amigo. This lessens my fatigue and increases my range terrifically, but it also shouts out to the world, "Here is a woman who can't stand on her own two feet." At the same time, paradoxically, it renders me invisible, reducing me to the height of a 7-year-old, with a child's attendant low status. "Would she like smoking or nonsmoking?" the gate agent assigning a seat asks the friend traveling with me. In crowds I see nothing but buttocks. I can tell you the name of every type of designer jeans ever sold. The wearers, eyes front, trip over me and fall across my handlebars into my lap. "Hey!" I want to shout to the lofty world, "Down here! There's a person down here!" But I'm not, by their standards, quite a person anymore.

My self-esteem diminishes further as age and illness strip from me the features that made me, for a brief while anyway, a good-looking, even sexy, young woman. No more long, bounding strides; I shuffle along with the timid gait I remember observing with pity and impatience, in the little old ladies at Boston's Symphony Hall on Friday afternoons. No more lithe girlish figure: my belly sags from the loss of muscle tone, which also creates all kinds of interesting disruptions, hopelessly humiliating in a society in which excretory functions remain strictly unspeakable. No more sex, either, if society had its way. The sexuality of the disabled so repulses most people that you can hardly get a doctor, let alone a member of the general population, to consider the issues it raises. Cripples simply aren't supposed to "Want It," much less "Do It." Fortunately, I've got a husband with a strong libido and a weak sense of social propriety, or else I'd find myself perforce, practicing a vow of chastity I never cared to take.*

Critical Thinking Questions

1. How does Nancy's view of herself as a "good-looking, even sexy, young woman" change as the MS progresses?
2. What impairment-based difficulties and participation restrictions are described?
3. How do you explain her use of language referring to disability, particularly her use of the word *cripples*?

*This excerpt was originally published in *Staring Back: The Disability Experience from the Inside Out*⁵⁴ and is Nancy Mairs's autobiographic account of living with multiple sclerosis.

Occupational therapy (OT) has the overarching goal to promote independence and self-direction with those whose lives include the experience of disability. Since the early 1980s, the independent living movement has gained both scholarly and public support to promote the same end goal and has transformed models of disability, as well as the ways we think about disability. How the occupational therapy practitioners, as members of the healthcare and rehabilitation team, and independent living movement activists, composed primarily of leaders with disabilities, interact can lead to a marriage of commonly held goals or produce a battleground of cross purposes. This chapter describes the ways that occupational therapists (OTs) may approach a call for an accord with activists.

Social scientists, such as Irving Zola, who had both high academic, scholarly credentials and personal experience with physical disability, began an infusion of their work into the rehabilitation and social program literature in the early 1980s. *Missing Pieces: A Chronicle of Living with a Disability*⁹¹ and *Ordinary Lives: Voices of Disability and Disease*⁹² provide an insider's discovery of the then unspoken social experience of disability that had been concealed in plain view. Zola's field notes chronicle a discovery self-framed within the social status of the researcher having a physical disability that others could easily see. For many also drawn to the independent living movement, it was the proverbial elephant in the room, finally acknowledged in their professional lives.

The independent living movement, which achieved public recognition in the early 1970s, is a political social justice, civil rights challenge to prior disability policy, practice, and research.²³ It is aligned with other minority groups (e.g., race, gender, ethnicity) in a call for equality in the dominant society, a civil rights movement, founded on the idea that the difficulties of having a disability are primarily based on the myths, fears, and stereotypes established in society today.⁷⁰ This movement seeks to modify the convention of habituating the isolated individual with disability through social and environmental changes.⁷⁰ A major political achievement was passage of the Americans with Disabilities Act (ADA) signed into federal law in 1990 and the enactment of the ADA Amendments Act of 2008 (see Chapters 2 and 15). This civil rights movement has had its share of detractors, including representatives of the healthcare industry, but sustained an expansive momentum.³⁷

The social justice movement successfully entered the international arena on May 3, 2008, with the United Nations' Convention on the Rights of Persons with Disabilities (CRPD). The CRPD obligates states to provide equal access to healthcare and related services for people with disabilities, and represents the first legally binding international instrument that specifically protects the rights of some 650 million such people worldwide. It is also the first treaty in which nongovernmental organizations were present during negotiations and could make interventions. People with disabilities participated as members of organizations of

persons with disabilities, state delegations, and UN organizations. Partly because of this inclusive process, the CRPD has received wide support, with 143 states having signed and 71 states having ratified the instrument.

The core principles of the CRPD include respect for human dignity, nondiscrimination, full participation, social inclusion, equality of opportunity, and accessibility.⁷⁶

- The relationship between occupation, justice, and client-centered practice is increasingly a focus of the OT profession.¹⁵
- Occupational therapy proclaims the necessity and power of occupation in the everyday lives of all human beings. The disruption and return of occupation for those with disability is our therapeutic focus. Health is supported and maintained when individuals are able to engage in their valued occupations. Occupation always occurs within the context of interrelated conditions that will affect client performance.³

The social and personal context of disability is inextricably linked when considering the lived experience of those with disability and ways to facilitate engagement in occupation. This chapter seeks to illuminate these contexts so that valued goals are achieved.

Client-Centered Self-Report

A justified complaint by those who have found their voice within the independent living movement is that medical and rehabilitation professionals focus on the attempt to classify an individual and do not listen to the personal account of the individual with the disability.^{42,59} The medical rehabilitation tradition of case presentation seeks to frame the individual with the disability in the professional's point of view. There can be numerous goals for a "case" description: treatment justification, entitlement to support services, legal testimony as an expert witness, reimbursement of costs, social science research, educational process, and the like. The role of the occupational therapist is to work with the client to achieve an individual desired outcome.⁷⁹ Occupational therapists are called to create a client-centered description of the individual's occupational self, one that must include the interrelated conditions of the social and personal context both surrounding and within the client. We must include the personal view of his or her own context in order to frame an accurate occupational picture that is responsive to individual values and goals.

Personal Context

Disability Experience

People who acquire disability share the common experience of feelings of shame and inferiority, along with avoidance of being identified as a person with disability.⁸⁷

Neuroscience research, using state-of-the-art brain imaging, confirms what biologic, psychological, and

sociologic studies and theory have posed; chiefly, that humans are social beings and a neurologic response at the most basic physiologic level is evident when conditions of social interaction are varied.² In short, we are drawn toward interaction with “our kind,” and isolation from others may be deemed socially abnormal.

Community psychologists note that the individual forms an identity in relation to the social environment. In discussing those who deviate from societal-based norms, problems arise when individuals are assigned an identity and status that is demeaning and lacks elements of personal choice and human rights.⁶³

A commonly experienced effect of having a disability is the social stigma associated with all individuals with a disability regardless of the condition.⁸² The psychological effects of being labeled a “disabled individual” is considered to be the process of devaluation. To be continuously perceived as an individual “blemished” in form or function is psychologically demeaning, regardless of the nature of the individual condition.⁸² The broadness of the term *disabled* imbues each individual with a disability with characteristics that are outside the norm.⁸²

The individual with a disability must attend to an array of stimuli perceived as abnormal: some biologic, such as being paralyzed; some environmental, such as inaccessible entrances; and some social, such as the patronizing behavior of others or preferential access to an event. It is a continuous flow of perceptions, which are not experienced by those who are not disabled. In short, many of the experiences of an individual with a disability are not shared by the normative society. Isolation and a lack of accord with one’s thoughts and feelings compound the list of non-normative situations.⁸²

In defining the experience of disability, social scientists⁸² and psychologists have constructed what can only be described as the psychology of disability. Of interest, however, is that by exploring the differences inherent in the social experience of the individual with a disability, the gap in perceived differences from the social norm may be widened by exaggerations. Thus, the devaluation of the individual with a disability may be perpetuated by those seeking to understand and even modify the conventional social perceptions. The fact is, human beings are more alike than different, regardless of variances in their physical bodies, sensory capacities, or intellectual abilities.¹⁴

It has been suggested that individuals with a disability shape their personal identities and social conception from their personal experiences through the modes of nonconformity and the outcomes of interactions with others in society. Specifically, if the individual considers his or her situation as nonconformative, it is due to the imposition of external societal factors and not a symptom of a condition.⁷⁴ What is actually known about the similarities and differences between people with and people without disability? Siller reported that as soon as one departs from the direct fact of disability, evidence can be provided to demonstrate

that persons with disabilities do or do not have different developmental tracks, social skills and precepts, defensive orientations, empathetic potential, and so on. The data suggest that if the disabled do present themselves as different, it is often a secondary consequence of the social climate rather than inherent disability-specific phenomena.⁷⁴

Another study⁸³ reported that a group of people with disability showed no differences in life satisfaction, frustration, or happiness, compared with a group without disability. The only difference found was on ratings of the difficulty of life. People with disability judged their lives to be more difficult and more likely to remain so. For example, people with chronic, but not fatal, health problems may not only seem to be quite happy but also may derive some happiness from their ability to cope with their difficulty. We may question the assumption that physical limitations are directly related to happiness. Instead, many people with disabilities may find happiness despite their disabilities, even though the able-bodied public may expect otherwise.

Individual Differences

Social scientists observe that an individual’s reactions to having disability are influenced not only by the time of onset, type of onset, functions impaired, severity and stability, visibility of disability, and the experiences of pain, but also by the person’s gender, activities affected, interests, values and goals, inner resources, personality and temperament, self-image, and environmental factors.⁸²

Vash and Crewe believed that different disabilities (such as blindness or paralysis) generate different reactions because each creates different problems or challenges.⁸² However, the insider-outsider perspective also applies to people with disability. Thus, the person with disability may feel that his or her condition is not as difficult as that of others. For example, a person who is blind may feel that it would be worse to be deaf. This idea has also proven to hold for the severity of the individual condition. A person with the inability to walk may have the view that this disability is not nearly as difficult as someone without legs. Reactions are also tempered by the impact of the disability on the valued skills and capacities the person has lost. For example, a person who loves music more than the visual arts, such as photography, may have a stronger reaction to loss of hearing than a person who had a more dominant inclination with another sensory channel (e.g., a “visual person” with the opposite pattern). Similarly, the severity of disability may not have a direct, one-to-one relationship with the person’s reaction to it. (Note the use of the word *may* throughout this paragraph, indicating that reactions are individualized and unpredictable.)

The visibility or invisibility of impairment may influence a person’s response to his or her disability because of social reactions. For example, invisible disabilities such as pain may create difficulties because other people expect the person to perform in impossible ways. One woman with arthritis indicated that it was easier for her to go grocery

shopping when she wore her hand splints because then her disability was visible and people would carry her packages for her without her having to ask.⁸²

The stability of the disability or the extent to which it changes over time may influence reactions both for the individual with a disability and for those surrounding him or her. In some progressive disabilities the individual faces uncertainty as to the degree of limitations, as well as (in some cases) a hastened death. Reactions to such disabilities are shaped by these realities and by what the affected people tell themselves about their projected futures.⁸² When hope for neither containment nor cure is substantiated, the person may experience a new round of disappointment, fear, or anger. The prospect of a terminal condition can affect each person in individual ways. Some individuals may ignore even the experience of pain, which tends to overtake consciousness. Reactions to pain are highly influenced by culture. Particularly important for occupational therapists is the issue of finding and implementing resources to assist the client in developing effective and gratifying lifestyles. The activities and behavior patterns affected by an impairment become the focus of the OT. Core issues addressed by the OT must include the individual client's spiritual or philosophic base (i.e., what makes the individual fulfilled).

Gender has also been found to elicit some of the most problematic issues for clients in their relationships with others. Gendered societal expectations dictate that individuals strive toward achieving, often idyllic, sexual roles. For example, the ideal for women to be physically perfect specimens or to carry the major responsibility for managing the home and caring for children may be of more concern for a female client than a male client.

Temporal elements of activity are part of the impact of disablement. The ways it interferes with what one is doing, with the interruption of ongoing activities, will influence the person's reactions. Additionally, activities never done but imagined as future goals also may be equally powerful influences in the person's reactions.

Interests, values, and goals influence a person's reaction to his or her disablement. The individual with a limited range of interests may react more negatively to a disability that prevents his or her expression, whereas an individual with a wide range of interests and goals may adapt more readily. Many people may not even be aware of their own interests, values, and goals and, therefore, may not be conscious of the ones that have the potential to lead to satisfaction after acquiring a disability. Thus, the client with multiple interests, activities, and goals has a greater probability of attaining engagement in satisfying activities. The resources that the individual possesses for coping with and enjoying life are assets that may counterbalance the devastation of loss of function. Some of these, such as social skills and persistence, may be developed to a level enabling paid employment, whereas others, such as artistic talent or leisure skills, may contribute to a more satisfying life.⁸²

An often overlooked aspect of the individual with a disability is the importance of spiritual and philosophic beliefs toward that person's disablement. People who acknowledge a spiritual dimension of life and who have a philosophy of life into which disablement can be integrated in a meaningful, nondestructive way may be better able to deal with having a disability.⁸² Specific religious beliefs may or may not be helpful. The person who views having a disability as punishment for past sins will respond differently from one who views the disability as a test or opportunity for spiritual development.

Lastly, the OT must acknowledge the importance of the person's environment in influencing his or her reactions to having disability. Immediate environmental qualities such as family support and acceptance, income, community resources, and loyal friends are powerful contributors. The institutional environment if one is hospitalized also has a profound effect, especially the attitudes and behaviors of the staff members. The culture and its support (or lack thereof) for resolving functional problems or protecting the civil rights of people with disability is another significant influence.

Stage Models of Adjustment to Disability

The medical model generally provides the medical rehabilitation team with a four-stage process of adjustment or adaptation to the experience of disability (Box 6-1).⁵⁶

Evidence only exists for emotional distress, commonly experienced as an initial response, and that it tends to diminish over time, but even that is not universal. Rehabilitation researchers are turning to a far more complex process of involving changes in the body, body image, self-concept, and the interactions between the person and the environment. For example, little attention has been given to individual personality differences (i.e., personal context), well recognized as contributors to all human endeavors (e.g., work, marriage, play, education, and occupations) expressed in an environment. Rather, the disability has been seen as the sole determinant of the individual personal experience.

The terms *adaptation*, *adjustment*, and *acceptance* are commonly applied to the process of resolving the negative experiences of having a disability. In recent years, social scientists aligned with the social model of disability have questioned the usefulness of such terms. They point out the preoccupation by service professionals with the psychological loss, or stages of bereavement, process to describe appropriate adjustment by those with an impairment. The studies usually cited, which contain a four-stage process of psychological adjustment and rehabilitation applied to those with spinal cord injury, are troublesome for the social model scientists.⁸ That process is usually thus: the initial reaction of shock and horror is followed by denial of the situation, leading to anger at others, bargaining, and finally to depression as a necessity for coming to terms with the acquired impairment. The acceptance, or adjustment, process takes

Box 6-1

Four-Stage Process of Adjustment to Experience of Disability

Stage 1: Vigilance

Becoming engulfed at the initial point of injury or acute illness. Within the intense, immediate crisis of the event, many individuals report a separation of the subjective and objective body. They experience an internal state of calmness contrasted with outward behavior of extreme distress and screaming in response to severe pain. The stage ends when the person surrenders to care of others, often emergency medical personnel.

Stage 2: Disruption

Taking time out, a disruption of reality, often described as feeling as if in a fog. Significant others do not merely provide emotional support but serve as an orienting force in an otherwise confusing, chaotic environment; they serve as an emotional anchor in a disordered world of the acute care medical environment.

Stage 3: Enduring the Self

Confronting and regrouping, improvement in reality orientation with the implications of the injury recognized. This is the stage

at which the severity of the physical limitations is faced.

Support from others is needed to control a sense of panic and fear of the diminished physical ability. At this stage even small gains witnessed in therapy sessions are interpreted as evidence that a full recovery is possible. This preserved sense of hope to reclaim previous abilities may help endure the initial healing process from burns, amputations, and spinal cord injuries, by holding onto the faith in medical miracles and return to prior physical ability.

Stage 4: Striving to Regain Self

Merging the old and the new reality is marked with frustration in attempting to regain previously taken-for-granted tasks such as walking and feeding oneself by the use of compensatory methods. There is a feeling of exhaustion in developing new routines, frustration with the limited physical capacity to participate in a range of activities, and a need to reformulate goals.

Adapted from Morse JM, O'Brien B: Preserving self: from victim, to patient, to disabled person, *J Adv Nurs* 21:886, 1995.

one to two years to resolve.⁸ The process draws from Kübler-Ross's seminal work describing the grief process, stages of loss of those who are dying, with an implicit assumption that the former, nondisabled self is dead and must be mourned.⁴⁴

The social model views the notion of adaptation, adjustment, or acceptance with an unjust society as abhorrent at the most basic level of human rights and social justice. Other minority groups have not tolerated such treatment within democratic societies, and disability rights activists believe that those with disabilities should not either. They point to a major flaw in these stage models: what about the physical condition that is progressive in nature (such as multiple sclerosis, rheumatoid arthritis, etc.) or limiting, physical changes as the body ages associated with lifelong disorders, such as spina bifida, or early in life trauma, such as spinal cord injury, or post-polio? The stages-of-loss concept common with the medical model gives little to community-based occupational therapy in which the issues of chronic or progressive disability-related problems are more typically addressed. One might speculate that the stage-of-loss concept, at best, suits the emotional needs of clinicians to have a sense of closure and resolution as patients move out of acute medical rehabilitation.

There has always been tension between the medical model of disability, which emphasizes an individual's physical or mental deficit, and the social model of disability, which highlights the barriers and prejudice that exclude people with disabilities from fully engaging in society and accessing appropriate healthcare (see [Chapter 2](#)).

Unfortunately, one of the biggest barriers to accessing appropriate healthcare is the attitude of health professionals, which might further isolate and stigmatize people with disabilities. Despite what many health professionals might assume, people with disabilities can be healthy, do not necessarily need to be "fixed," are often independent, and might well be consulting for a reason unrelated to their disability. Conversely, people with chronic conditions, such as chronic obstructive pulmonary disease, are often debilitated by their condition yet are often not perceived by health professionals as having a disability. Such perceptions matter: people with disabilities still have the same health needs as other people and are entitled to specific rights, including the right to make choices about their healthcare.⁸⁸

In contrast, bioethicist Singer has posed that healthcare rationing decisions should be quantified by using a quality-adjusted life-year, or QALY, which might assess the relative value of life with a disability to a nondisabled one,⁷³ which is in stark contrast to a social justice model, with each individual possessing equal value.

Stages of Life and Self-Concept

Many views of the individual and groups of people divide the human life cycle into three categories: childhood, adulthood, and the elderly. Its stages, statuses, and transitions are constructed in large by social institutions (i.e., the family, economic demands, and education) and the dominant culture. One might expect that by identifying the onset of a physical impairment in the life cycle, one may know the trajectory of many factors including self-concept. The stage

of life at which disability occurs is thought to influence the person because it affects the way he or she is perceived by others and the developmental tasks that might be interrupted. In that vein, the three main trajectories commonly identified are as follows: (1) people whose impairment is diagnosed at birth or in early childhood, (2) those who acquire an impairment during the adolescent or early adult years, usually through illness or injury, and (3) older people whose impairment is most often attributed to the aging process.⁸

The person who is born with disability or acquires disability in infancy or childhood may experience isolation or separation from the mainstream in family life, play, and education. The trajectory of an early onset disability is thought to include socialization with pervasively abnormal low expectations, and lifestyle, with few positive role models to exhibit alternative models. Families and special-needs schools may hide children with congenital impairments in order to protect them from discrimination and rejection from bullying peers. A “disabled identity” results from the child with a disability, growing up in a household and community with no other disabled person, lengthy periods of hospitalization, segregated special education, or a largely inaccessible physical environment.⁸

A 2003 study of self-image of a group of Swedish young persons with cerebral palsy revealed that most respondents viewed themselves in a very positive manner and rated markedly higher self-image than norm groups.¹ The influence of a generally positive or negative attitude toward oneself formed early in life and the sparse interaction with others outside of the family are posed as explanations of the research findings. Future studies must focus on the relationship between self-image and the social interaction with persons outside the immediate family as the individual with an impairment begins to interact with a wider social group.

Barnes and Mercer have concluded that many youth with disabilities do not experience the full impact of disablement until they seek to participate in more peer-directed leisure pursuits or are expected to join the workforce. When young people with disabilities are compared with nondisabled peers, they report lower job aspirations, poor or non-existent career advice, employer discrimination, and a feeling of marginalization in the job market. There is evidence that the age of key major life transition indicators—such as leaving home, getting married, becoming a parent, and entry into the job market—occurs later among those with disabilities compared with those without disabilities.⁸

One cannot assume there will be continuing negative effects on self-esteem if there is an early onset disability. A longitudinal study found that although adolescent girls with cerebral palsy scored significantly lower on physical, social, and personal self-esteem evaluations, as adults the same individuals no longer scored significantly different from able-bodied groups.⁵³ The authors speculated that factors in their subjects’ changed self-esteem may have been due to an expanded range of environments in which to interact, better

social relationships, or a wider variety of experiences in education, work, and commerce (than in earlier years).

A study of self-evaluations of global self-worth in adolescents with disability (e.g., cerebral palsy, orofacial clefts, and spina bifida) found that the participants did not differ from those of an able-bodied comparison group (the assumption that self-esteem is necessarily reduced by a disability effect needs to be reassessed in light of recent studies).⁴³

A person who acquires disability later in life may face different issues, such as the need to change vocations, find a marital partner, or remain a part of his or her culture via the routines of daily life.^{11,82} Some are forced into a sudden and substantial reevaluation of their identities, perhaps reinforced within a short time period by downward economic and social mobility. A distinction can be made between those who experience discontinuity with a sharp shift into unemployment, contrasted with the drift of a more gradual process of downward mobility. Generally, a chronic illness is less drastic than an accident resulting in disability, affording the individual the opportunity to plan and adjust to threats to self-identity.⁸

It has been posed that individuals who acquire an impairment in middle age may, more often than those who are aged, view the onset of a disability as an unexpected, personal tragedy. In comparison, those who are aged, and those who surround them, both family and service providers, may interpret the disability experience as an inevitable fact of life and, therefore, more of a normal course of events.⁸

Social scientists are calling for research on those with disabilities that includes much more descriptive factors such as the visibility of the impairment, the distinct type of impairment, whether the impairment was preventable, the age of onset, the influence of public perception on the individual, and social interactions. Increasingly, many persons who have disabilities from various backgrounds are learning to think about disability as a social justice issue rather than as a category of individual deficiency. Some surveys have indicated that disabled Americans who are young enough to have been influenced by the disability rights movement are more likely than older counterparts to identify themselves as members of a minority group, namely, the disability community.³¹

Gill has called for “deindividualizing the problem of disability,”³¹ contrasting this view with seeing disability as a personal tragedy. In understanding the social determinants of the devalued status by challenging the disabling society, one reinforces the valid and whole feelings held by those who are disabled. Plainly stated, if the individual with a disability views personal experience as a problem highly influenced by factors outside of oneself, this perspective provides a way to effectively challenge societal perceptions of a devalued status.

Individuals with disabilities often demonstrate remarkable strength and achievement in the face of environmental obstacles and social exclusion. Those seeking to truly

understand the disability experience should consider the aspects of the disability identity that engender creativity and an enhanced awareness of many commonly unappreciated aspects of human experience.³¹

Understanding Individual Experience

To avoid turning a category such as disability into an inflexible framework for identity, occupational therapists must develop methods that elicit the personal experiences and opinions of those who are disabled.¹ The narrative process for discovery of the individual is a recommended method. The process relies less on observable behavior and more on how people use their own stories to gain an understanding of everyday experience and emotion. It allows us to analyze the ways that personal identity is shaped by social interaction while maintaining the individual studied as an active agent.⁸

Part of a therapy program for clients with a disability should include client-centered exploration into the individual perspective. Initially, to help better define the client perspective, research has shown that discussing the meaning of core categories can lead to insight about the feelings and attitudes of the client.²⁴ Examples of core meaning categories have included (but are not restricted to) illness, independence, activity, altruism, self-caring, and self-respect. Researchers demonstrated that the independence, activity, and altruism categories actively directed behavior before and during treatment, and that the last two meanings emerged as treatment progressed as a transformation process. Explanation of the categories identified should be a part of the rehabilitation intervention, with both therapists and clients benefiting from the increased awareness and self-reflection of the individual clients.

One study employed this phenomenological approach to describe the lived experience of disability of a woman who sustained a head injury 21 years before.⁵⁹ The woman identified themes of nostalgia, abandonment, and hope and what the core categories meant to her. More important than simply defining these terms, she reflected on how these meanings had shaped her life experiences for those 21 years. The outcome for this individual focused on changing her perspective from that of a passive victim to an active constructor of her own identity.⁸ Reevaluating these themes with the individual may allow both the therapist and the client to discover the unique disability experience.

Social Context

Social Status and Disability

The historical Chicago city ordinance recorded in [Box 6-2](#) is an example of the segregation and discrimination society has openly communicated to those with disabilities. A more extreme example is the extermination of 200,000 people with disabilities in the death camps of the Nazi regime in World War II. Our 21st century perspective may scoff and feel distanced from such obvious prejudice. These

Box 6-2

Chicago City Ordinance, 1911, Repealed in 1974

No person who is diseased, maimed, mutilated, or in any way deformed so as to be unsightly or disgusting object or improper person to be allowed in or on the public ways or other public places in this city, shall therein or thereon expose himself to public view.

may seem to be events consigned to another place, another time. To see our own present-day society behaving somewhere along the continuum that still includes discrimination and injustice is difficult. This is an inquiry we must not shy away from; the cost to our professional integrity would be too high without it; and, our ability to provide a useful service would be compromised without such an understanding.

Goffman's classic work³² used the term *stigma* to describe the social discrediting process in strained relations between disabled and nondisabled people³¹ that reduces the life chances of people with disability or other differences. In the process, an obvious impairment or knowledge of a hidden one signifies a moral deficiency. The individual with stigma is seen as not quite human. Society tends to impute a wide range of imperfections on the basis of the impairment.

As with individuals from other minority groups, those with disabilities are categorized with stereotypes. The standard definition of a stereotype is an unvarying form or pattern, a fixed notion, having no individuality, as though cast from a mold.⁸⁴ Stereotyping is part of the stigmatization process, applied to those perceived to exhibit certain qualities. Stigma may be expressed as a societal reaction to fear of the unknown. One explanation for stereotypes applied to those with disabilities is that little direct experience, despite recent mainstreaming in education and the removal of some environmental barriers, produces little real knowledge of what to expect in daily life.

Individuals with visible disabilities may be discredited in social situations, without regard for their actual abilities. "The exclusion of persons with physical disabilities from educational settings and work situations regardless of their ability to participate in and perform all required activities is well recorded in the literature."⁶⁹

Several researchers have noted the popular media portrayals of those with disabilities, forming and reinforcing the basis of our common stereotypes, even for those of us in health professions⁵⁹ ([Box 6-3](#)). For example, "Films present people with disabilities either condescendingly as 'inspirational,' endeavoring to be as 'normal' as possible by 'overcoming' their limitations, or as disfigured monsters 'slashing and hacking their way to box office success.'"²⁷ Cahill and Norden,¹⁸ in their discussion of such stereotypical characterization of women with disabilities in the media, found the two most frequent categories of portrayal: the

■ Box 6-3

Seven Media Depiction Images of “Handicapist Stereotypes”

1. *The disabled person as pitiable and pathetic.* Found in charity telethons, perpetuating the image of people with disabilities as objects of pity. Their stories are often told in terms of people who are victims of a tragic fate.
2. *The disabled person as Supercrip.* Heartwarming stories that depict great courage, wherein someone likable either succeeds in triumphing or succumbs heroically; these are usually considered “inspirational” stories. This image leaves a lot of ordinary people with disabilities feeling like failures if they haven’t done something extraordinary.
3. *The disabled person as sinister, evil, and criminal.* This stereotype plays on deeply held fears and prejudices; the disabled villain (especially one with a psychiatric illness) is almost always someone who is dangerous, unpredictable, and evil.
4. *The disabled person as better off dead.* The “better dead than disabled syndrome” is one way in which the media imply that with medical costs soaring and resources limited, a disabled person would seek suicide because life is unbearable. Society, especially the family, is thereby relieved of caring for the disabled individual, who is not whole or useful.
5. *The disabled person as maladjusted—his or her own worst enemy.* “If only disabled persons were not so bitter and would accept themselves, they would have better lives” is the general statement of this stereotype. Usually it involves a nondisabled person who helps someone with a disability see the “bright side” of his or her impairment. It contains the mythology that persons with disabilities need guidance because they are unable to make sound judgments.
6. *The disabled person as a burden.* Family responsibilities and duty form the core of this stereotype, which is built on the assumption that persons with disabilities need someone else to take care of them. Like the stereotype of disabled persons as better off dead, it engenders the belief that the burden, whether financial or emotional, is so compelling that it ruins families and their lives.
7. *The disabled person as unable to live a successful life.* The media have distorted society’s view of people with disabilities by limiting their presence in the portrayal of day-to-day life. Although more disabled people are beginning to appear in cameo-like scenes or as a walk-on extras, they are seldom seen in ordinary workplace situations or as happy, healthy family members.

From Switzer JV: *Disability rights: American disability policy and the fight for equality*, Washington, DC, 2003, Georgetown University Press.

disabled ingénue victim and the awe-inspiring overachiever. The disabled ingénue is young and pretty but significantly helpless because of her disability. The ingénue may be victimized or terrorized by others. Usually she is cured of her malady and able to return to the mainstream by the end of the story. Her return, or “reabsorption,” often produces an ability to have a new perspective on life. Similarly, the awe-inspiring overachiever is attractive and succeeds in reaching extraordinary levels of competitive acclaim only to be taken down by an incurable disability. She eventually “overcomes” her disability with unrelenting personal fortitude, and often unexplained economic resources.¹⁸

The traditional approach used in telethons or other fund-raising ventures, in which people with disabilities may be portrayed as victims, reinforces our negative attitudes, stereotypes, and stigma. More recently, with pressure from disability advocacy groups, some network television programs and commercials include people with disabilities as regular participants in daily life, as workers or family members.

Disability as a Collective Experience

Vash and Crewe recounted a rehabilitation conference a number of years ago when an address by a psychiatrist included the speaker alternatively standing up and then sitting back down in a wheelchair several times.⁸² The speaker challenged the audience to deny that their sense of his competence changed as he stood before them or sat in

the wheelchair. Vash reported that when discussion followed, most acknowledged that their perception of his competence fluctuated; the speaker was more credible and worth attention when he was standing. The demonstration forced them to acknowledge their own, previously denied, prejudice and was emotionally charged for much of the audience. A wheelchair can be a powerful social symbol, conveying devaluation of the person in it.

Zola⁹¹ observed that, at its worst, society denigrates, stigmatizes, and distances itself from people with chronic conditions. He experienced little encouragement to integrate his disability identity into his life because this would be interpreted as foregoing the fight to be normal. In letting his disability surface as a real and not necessarily bad part of himself, he was able to shed his super strong “I can do it myself” attitudes and be more demanding for what he needed. Only later did he come to believe that he had the right to ask for or demand certain accommodations. He began to refuse invitations for speaking engagements unless they were held in a fully accessible facility (not only for him as the speaker, but also for the audience).

Another insider’s view of disability is provided by Robert Murphy,⁵⁷ an anthropologist who developed a progressive spinal cord tumor that ultimately led to quadriplegia. His account particularly captures the medical and rehabilitation setting from the perspective of the client. He described his initial reaction: “But what depressed me above all else was the realization that I had lost my freedom, that I was to be

an occasional prisoner of hospitals for some time to come, that my future was under the control of the medical establishment.”⁵⁷ He reported the feeling as like falling into a vast web, a trap from which he might never escape.

The hospitalized individual must conform to the routine imposed by the medical establishment. For example, Murphy spent 5 weeks on one ward where he was bathed at 5:30 every morning because the day shift nurses were too busy to do it. The chain of authority from physicians on down creates a bureaucratic structure that breeds and feeds on impersonality.⁵⁷ The totality (of social isolation) of such institutions is greater in long-term care facilities, such as mental health and rehabilitation centers. A closed-off, total institution generally attempts to erase prior identity and make the person assume a new one, imposed by authority. The hospital requires that the “inmates” think of themselves primarily as patients, a condition of conformity and subservience.

Murphy highlighted the experience of an increased social isolation as some of his friends avoided him.⁵⁷ He often encountered physical barriers in his environment, which restricted opportunities for social contact. He applied a term from anthropology, liminality, to the observation that people with disability have the social experience of pervasive exclusion from ordinary life, the denial of full humanity, an indeterminate limbo-like state of being in the world, in other words, the marginal status of individuals who have not yet passed a test of full societal membership. Those with such social status have a kind of invisibility; as their bodies are impaired, so is their social standing. “Caught in a transitional state between isolation and social emergence” people with disabilities “do not count as proven citizens of the culture.”³¹ This limbo-like state affects all social interaction. “Their persons are regarded as contaminated; eyes are averted and people take care not to approach wheelchairs too closely.”³¹ One of his colleagues viewed wheelchairs as portable seclusion huts or isolation chambers.

Murphy was surprised to discover that in attending meetings of organizations formed by people with disability, often more attention was paid to the opinions of experts who were able bodied than to his views, in spite of his having disability and being a professor of anthropology.⁵⁷ Those with disabilities may hold the same social attitudes from the culture about disability and behave in ways consistent with those negative views.

A major aspect of Murphy’s life was his work as a professor, which he continued as long as possible. But even with his status as an internationally recognized anthropologist and researcher, hospital personnel often saw him as an anomaly. A hospital social worker asked him, “What was your occupation?” even though he was working full time and doing research in areas related to medical expertise. With their mindset, hospital workers seemed unable to place him in the mainstream of society. Murphy concluded that people with disability must make extra efforts to establish themselves as autonomous, worthy individuals.⁵⁷

Gill stated:

In certain ways, many disabled persons are forced to lead dual lives. First, they are repeatedly mistaken for something they are not: tragic, heroic, pathetic, not full humans. Persons with a wide range of impairments report extensive experience with such identity misattributions. Second, disabled people must submerge their spontaneous reactions and authentic feelings to smooth over relations with others, from strangers to family members to the personal assistants they rely on to maneuver through each day.³¹

Murphy’s book ended with this observation: “But the essence of the well-lived life is the defiance of negativity, inertia and death. Life has a liturgy which must be constantly celebrated and renewed; it is a feast whose sacrament is consummated in the paralytic’s breaking out from his prison of flesh and bone, and in his quest for autonomy.”⁵⁷

Wright, a social psychologist, studied and wrote about society’s reactions to people with disability for many years.⁸⁷ She used the term *spread* to describe how the presence of disability or an atypical physique serves as a stimulus to inferences, assumptions, or expectations about the person who has disability. For example, a person who is blind may be shouted at, as though lack of vision indicates impaired hearing as well, or a person with cerebral palsy and a speech impairment may be assumed to be mentally retarded. One extreme manifestation of spread is the belief that an individual’s life must be a tragedy because of having a disability. This attitude may be expressed in such statements as “I would rather be dead than have multiple sclerosis.” The assumption that the presence of a disabling condition is a life sentence to a tragic existence denies that satisfaction and happiness may ever be achieved. This attitude is of particular ethical concern today, when genetic counseling and euthanasia may provide a socially acceptable means of exterminating people with disability.⁸⁰ If life is seen as tragic or not worth living, it is a fairly easy step to argue that it would be better for everyone if people with disability ceased to exist.⁶²

Wright’s work describing efforts to integrate disability with a positive sense of self has explicit recognition that the devalued status of those with disability is imposed on such persons collectively.³¹ Gill pointed out that individuals with disabilities make assessments (of asset values in comparison with comparative-status values) in terms of contributions to one’s life. She used the example of the skill in using adaptive equipment; although others may judge the use of such devices as inferior (compared with “normal” functioning), persons with disabilities regard them as assets because they have learned to appreciate the benefit derived from their use.³¹

Occupational Therapy Practice and the Independent Living Philosophy

Until recently, much of the emphasis in rehabilitation has been on modifying the individual to adapt to the existing environment. Individuals have been modified by machines,

surgery, physical therapy, occupational therapy, psychotherapy, vocational counseling, social work, prosthetic and orthotic devices, education, training and so on.⁸² This emphasis on modification of the person is termed the medical model (or biomedical model) of intervention. It is based on the thought that there must be intervention, treatment, repair or correction of pathology, of that which is a deviation from the norm. The norm may be physiologic, anatomic, behavioral, or functional. The cause of problem, in this model, is intrinsic to the person; normalization is the goal. In contrast, these normalization models are considered erroneous and dangerous by those aligned with the independent living philosophy, the social model of disability. Of particular concern is the tendency to isolate specific differences and then use those differences to determine and explain the consequences at a societal level.²⁸ This tendency creates a kind of logical fallacy, in which the evidence for what is normal is then used to explain the resultant problems that prevent participation in society.

In his landmark article first published in 1979, DeJong described the differences between the medical rehabilitation model and the independent living model, and its sister, the social model of disability.²³ In the medical model, the physician is the primary decision maker, and healthcare professionals are considered the experts. The problem is defined as the patient's impairment or disease; the solution lies in the services delivered by the healthcare professionals. Oftentimes, the goal of rehabilitation is for the patient to be independent in activities of daily living (ADLs) performance. The client is expected to participate willingly in the program established by the healthcare professionals, and success is determined by the patient's compliance with the prescribed program and attainment of goals established by the medical rehabilitation team.¹⁴

Fleischer and Zames²⁷ pointed out that with the emergence of those with severe disabilities from secluded institutions in combination with independent living, strategies that produced participation in the community, a critical force gained momentum, creating the disability rights movement. Previously, many who became prime movers in the fledgling civil rights struggle for people with disabilities might have been hidden away in segregated institutions or become homebound. Edward Roberts, father of the worldwide independent living movement, had to sleep in an iron lung. Both Judith E. Heumann, the former assistant secretary of education and founder of Disabled in Action, and Roberts, of the World Institute on Disability, require attendant care for activities of daily living. In the 1990s, it was reported that Fred Fay, cofounder of the Center for Independent Living and the American Coalition of Citizens with Disabilities, would lie on his back all day, every day, managing not only his home but also state and national political campaigns and international disability advocacy programs using a combination of personal assistance and three computers.¹⁴

Bowen pointed out that occupational therapy practitioners should not deceive themselves into believing they are using an independent living, or social, model because the professional role is to help people live independently.³⁻⁵ This is merely a simple shift of words, not the core of the model. The independent living movement and the associated model are quite different and separate approaches to practice from the traditional medical model used by most practitioners.¹⁴

When the independent living model is used, the person receiving services is considered a consumer, not a patient; is the expert who knows his or her own needs; and is the one who should be the primary decision maker. In this model, the healthcare service provider describes what he or she can do with the consumer, and the consumer then decides what aspects of the service he or she wants to use. The foremost issues addressed are the inaccessible environment, negative attitudes held by others about disabilities, and the medical rehabilitation process, which tends to produce dependence on others. These problems are best resolved through self-help and consumer control of decision making, self-advocacy, peer counseling, and removal of attitudinal and architectural barriers. The goal of independent living is full participation and integration into the entire society.¹⁴

Consumer-controlled and consumer-directed independent living programs offering a broad spectrum of services, including some that occupational therapy practitioners have considered hallmarks of the profession, such as assistive device recommendation and daily living skills training, are funded through federal, state, local, and private resources. In 1993, the American Occupational Therapy Association (AOTA) published a position paper outlining the role of occupational therapy in such programs. The general practice of the professional per se does not differ from other settings. The major difference is that the consumer selects which services to use, rather than receiving those chosen by the therapist. With the community-based nature of the settings, as contrasted with healthcare facility-based settings, the services are directly related to the consumer's ability to function within his or her roles in the local community. The practitioner may need a higher level of creativity to address the diverse role-related functional activities.

OT Practice Notes

The independent living philosophy requires that the therapist play a supporting role in helping the consumer be the principal player as problems with the environment are solved. This role contrasts with the therapist's more common approach in which therapeutic activities are directed to restore abilities.¹⁴

Bowen stated that practitioners often fall short in implementation of an independent living philosophy, namely, striving to make others aware of the handicapping nature of the environment. The focused goal, using the independent living philosophy, is on problems that reside in the physical and social environment, not on a deficit within the person with a disability. Research noted that practitioners write therapeutic goals that seek to change the client 12 times more often than goals that focus on altering the environment.¹⁴ Other occupational therapy researchers reported an extreme lack of practitioners' knowledge related to architectural accessibility regulations that, thereby, compromised their ability to promote integration into the community and empower consumers who use wheelchairs.⁶⁴

Person-First Language

The language used to communicate ideas about people with disability is important because it conveys images about the people that may diminish their status as human beings. Kailes, a disability policy consultant who has a lifelong disability, wrote, "Language is powerful. It structures our reality and influences our attitudes and behavior. Words can empower, encourage, confuse, discriminate, patronize, denigrate, inflame, start wars and bring about peace. Words can elicit love and manifest hate, and words can paint vivid and long lasting pictures."³⁸ For example, in the jargon of the medical environment, disabled people may be called "quads," "paras," "CPs" or "that stroke down the hall." Such categorization leads to viewing individuals as stereotypical examples, engulfed by their impairments.¹³ Some individuals are of the opinion that referring to people as "the disabled" or "a disabled person" makes the disability swallow up their entire identity, leaving them outside the mainstream of humanity. How, then, might occupational therapy practitioners use language in a spirit of dignity?

Switzer noted in her discussion of the complexities of disability policy that there is

virtually universal agreement that pejorative terms that objectify disabled persons (such as deformed or wheel-chair bound) diminish the importance of the individual and create the perception of people only in terms of their disability. Similarly, attempts to develop euphemisms (physically challenged, height-impaired) generally are thought to be misguided attempts that still identify persons by their disability alone.⁷⁷

For persons with disabilities (PWDs) to develop a sense of pride, culture, and community, past negative attitudes must be changed. The use of language that recognizes that the person comes first, namely, a person with a disability, is yet again another acknowledgment that the individual is a human being before being someone with a disability.⁷⁷ This shift in use of language is widely known as person-first language.⁴⁷

All struggles for basic human rights have included the significant issue of what labels will be used by and about a

particular people. With other minority groups, examples include the following: "Negro" was replaced by "black" and then changed to "African American"; "Indian" changed to "Native American" or "People of First Nations"; and "ladies" or "girls" are now more commonly called "women." Kailes has reminded us that terms such as *crippled*, *disabled*, and *handicapped* are labels imposed from outside the community of people with disabilities, from definitions constructed by social services, medical institutions, governments, and employers. The preferred terms continue to evolve and change. Negative attitudes, values, biases, and stereotypes can be amended by using disability-related language that is precise, objective, and neutral. Disability-related terms are often subjective and indirectly carry a feeling or bias through innuendo and tone. But the effect of these terms on those with disabilities can be very direct and disturbing with a sharp cringe, a flash of anger, or shutting down the interaction when confronted with "ablest" and "handicapist" language. Use of such language creates social distance, establishes an inequality in the interaction, and produces demeaning expectations.³⁸

What should we call the recipient of occupational therapy—*patient*, *client*, or *patient-client* (Box 6-4). *Patient* conveys both a sense of ethical responsibility⁶⁶ by practitioners, as well as passivity and dependence⁵⁷ for those people receiving care. *Client*, on the other hand, conveys merely an economic relationship,⁷¹ as does *consumer*. One might sell a product or service to a client with the buyer beware ethic of a free market economy, whereas our professional ethics demand the provision of service based entirely on the benefits it affords its recipients. Perhaps a sensitive inquiry by the therapist is needed, asking what term that particular individual prefers might give the answer.

Culture of Disability

Shapiro, a highly regarded journalist, wrote about the new group consciousness emerging through a powerful coalition of literally millions of people with disabilities, their families, and those working with them. He noted the start of a disability culture, which did not exist nationally even as recently as the late 1970s.⁷⁰ Barnes and Mercer,⁹ British social scientists, more recently stated that the disability culture is a sense of common identity and interests that unites disabled people and separates them from those who are non-disabled.

As Steven Brown, cofounder of the Institute on Disability Culture in Las Cruces, New Mexico, said:

People with disabilities have forged a group identity. We share a common history of oppression and a common bond of resilience. We generate art, music, literature, and other expressions of our lives and our culture, infused from our experience of disability. Most importantly, we are proud of ourselves as people with disabilities. We claim our disabilities with pride as part of our identity. We are who we are: we are people with disabilities.²⁷

□ Box 6-4

Use of Language

Disabled versus Handicapped

Handicapped connotes the negative image of a person on the street corner with a “handicap” in hand, begging for money. The word *disability* is not perfect, as it still implies a negative—what a person cannot do—but it has become the word that is most widely used and accepted among people with disabilities. A disability is a condition, and a handicap is a barrier or obstacle that a person with a disability may encounter in the environment. People are not handicapped by their disability all the time. A wheelchair user is not handicapped in an environment where there are no steps. A disability can mean that a person may do something differently as compared to a person without a disability, but with equal participation and equal results. The phrase *disabled people* is a shortcut to the more involved and sometimes more awkward but preferred expression *people with disabilities*. It depicts people with disabilities as people, with multidimensional characteristics in addition to their disability.

For example, a woman who has a disability as a result of polio and uses a wheelchair may also be a mother, a wife, an executive, a student, a citizen, a board member, a gifted public speaker, and more. A man who has quadriplegia as a result of an auto accident is not a “vegetable.” Although he has a significant physical disability, he may also be an active, contributing, productive member of society. Disabled people can represent differentness and separateness, and we sometimes reduce a person’s identity to only his or her disability; we don’t refer to people with broken legs as “broken-leg people.” An exception to this guideline is for people who are deaf who refer to themselves as the “Deaf with a capital D.” Many people who are deaf consider themselves members of a culture that has its own language. There is also emerging discussion within the disability community that supports the phrase *disabled people* as representing a sense of pride, culture, common history, and experience.

Wheelchair User versus Wheelchair Bound or Confined to a Wheelchair

People are not bound to wheelchairs. *Wheelchair bound or confined to a wheelchair* conveys a stereotype that sets people with disabilities apart from others and portrays people who use wheelchairs as devalued, impotent, slow, and passive. People use wheelchairs to increase their mobility, similar to the way people use cars. Many people who use wheelchairs can walk but choose to use a wheelchair or a scooter because of such functional limitations as reduced endurance, decreased balance, or slow walking speed. Often, ability, productivity, independence, ease, and speed of movement are increased by wheelchair use. For many, a wheelchair means increased mobility and freedom; it does not mean imprisonment! People who use wheelchairs can transfer to cars and chairs. Thus, they are neither confined nor bound to their wheelchairs.

Patient

Most people are patients at some point, but this does not mean that people are constant patients and always should be called patients. Patient is an adjective that frequently gets paired with people with disabilities. It is common to hear expressions like “a multiple sclerosis patient is in my class,” “he is an Alzheimer’s patient,” or “stroke patients walk in the mall every day.” The words conjure up a vision of a people walking in the mall with IVs and EKG wires attached to their chests and accompanied by their doctors. Pairing people with disabilities with *patient* over-medicalizes people. It gives them a permanent status of “eternal and chronic patients” and reinforces a common misconception that people with disabilities are all sick. People with disabilities are not constant patients and most people with disabilities are not sick.

Crippled

Crippled is derived from an old English word meaning “to creep.” Webster’s New World Dictionary gives a second meaning to the word *cripple*, which is “inferior.” These are derogatory images that perpetuate negative stereotypes!

Overcome

People cope with, adjust to, and live with a disability. Disability is a characteristic, and just as one does not overcome being black, one does not overcome having a disability. People overcome social, economic, psychological, attitudinal, architectural, transportation, educational, and employment barriers.

Special

People with disabilities should not be labeled as being *special*. Although the term is often used in descriptions such as *special education*, it is patronizing, inappropriate, and distancing. It is not necessary. *Special* is often viewed by the disability community as a euphemism for segregated, as it implies differentness and apartness.

Suffer

An individual who has a disability does not necessarily suffer. *Suffer* conveys a stereotypical attitude of never-ending mourning. If one wants to say a particular person is suffering, this point should be developed explicitly. Mourning is one of the stages involved in adjusting to disability. It is not a chronic state.

Victim

The word *victim* is appropriate to use immediately after a diagnosis, an injury, or for someone who has experienced some form of abuse (victim of a violent crime, accident victim, or rape victim). It is inappropriate to use the word to describe an ongoing status. A person is not a lifetime multiple sclerosis victim, cerebral palsy victim, or stroke victim. Being constantly referred to as a victim reinforces the helplessness and degradation of the initial experience.

From Kailes JI: *Language is more than a trivial concern!* 1999, Author (available from www.jik.com).

The notion of “disability pride,” as an echo of “black pride” or “gay pride,” was dismissed as unachievable even within independent living movement circles during the mid-1970s. In the summer of 2004, however, was the first Disability Pride Parade in Chicago. Sarah Triano, Disabilities Pride Parade Planning co-chair, said, “It takes a lot for people with disabilities, particularly non-apparent disabilities, to get to a place where they openly and proudly identify themselves as disabled. Just as in other social/human rights movements, the first arena of acceptance comes from the internalized feelings of pride and power.” She went on to say, “It’s time that we reclaim the definition of Disability and take control over the naming of our own experience ... disability is a natural and beautiful part of human diversity ... The barrier to be overcome is not my disability; it is societal oppression and discrimination based on biologic differences (such as disability, gender, race, age, or sexuality)” (www.disabledandproud.com/selfdefinition.htm).

The emergence of the disability arts movement marks a significant stage in the transition to positive portrayal of disabled people building on the social model of disability. From the mid-1980s, there has been a substantial increase in work by disabled poets, musicians, artists, and entertainers that articulates the experience and value of the “disabled” lifestyle.⁹ Art, literature, and performance, from the time of Shakespeare to the present day Axis Dance Company, aspire to convey the universality of human experience that we all share. For more than 20 years, the late John Callahan, an irreverent cartoonist and self-stated “quadriplegic in a wheelchair” depicted a point of view of life, including the experience of disability, which was published in newspapers across the nation.⁵⁵ Callahan’s autobiography, *Don’t Worry He Won’t Get Far on Foot*, made it to the *New York Times* bestseller list.

“Disdainful of pity, disability culture celebrates its heritage and sense of community, using various forms of expression common to other cultures such as, for example, film, literature, dance, and painting.”²⁷ The UCLA National Arts and Disability Center is dedicated to promoting the full inclusion of children and adults with disabilities into the visual-, performing-, media-, and literary-arts communities. *Beyond Victims and Villains: Contemporary Plays by Disabled Playwrights*⁴⁹ and *Bodies in Commotion: Disability and Performance*⁶⁷ are well-regarded examples.

Sports and games, heralds of cultural pursuit, are also evident in the culture of disability. The term *disabled athlete* has been reclaimed from sports medicine and orthopedics to mean competitive athletes with disabilities. Every major city marathon includes “runners” with wheels. The international Paralympics occur every four years in tandem with the Olympic Games, with 4000 entrants from 130 countries (www.paralympic.org). The 2005 film *Murderball*,³⁶ about athletes with paraplegia who play full-contact rugby in Mad Max–style wheelchairs and who competed in the Paralympic Games in Athens, Greece, was nominated for an Oscar from the Academy of Motion Pictures (IMDb, Inc.,

www.imdb.com/title/tt0436613). In another example, professional wheelchair skaters are showcased at skate parks.²⁶

Charlton’s *Nothing about Us without Us: Disability Oppression and Empowerment* details the worldwide “grass-roots disability activism” of those with disabilities. He stated, “A consciousness of empowerment is growing among people with disabilities ... it has to do with being proud of self and having a culture that fortifies and spreads the feeling.”¹⁹

The well-known journalist and author of *Moving Violations, A Memoir: War Zones, Wheelchairs, and Declarations of Independence*,³⁵ John Hockenberry, who had a spinal cord injury and uses a wheelchair, sees disability in a novel way, as a cultural resource, and is quoted as follows:

Why is it that a person would not be considered educated or privileged if he went to school and never learned there was a France or a French language? But if a person went through school and knew nothing about disability, never met a disabled person, never heard of American Sign Language, he might be considered not only educated, but also lucky? Maybe we in the disability community need to get out of the clinical realm, even out of the equity realm, into the cultural realm, and show that a strategy that leads to inclusion makes a better community for everyone.³⁵

Murphy, in *The Body Silent*,⁵⁷ described how his degenerative disability impelled him to examine the society of people with disabilities with the same analytic tools he used to study esoteric cultures in remote geographic areas, the classic field study location of his discipline. He stated:

Just as an anthropologist gets a better perspective on his own culture through the long and deep study of a radically different one, my extended sojourn in disability has given me, like it or not, a measure of estrangement far beyond the yield of any trip. I now stand somewhat apart from American culture, making me in many ways a stranger. And with this estrangement has come a greater urge to penetrate the veneer of cultural differences and reach an understanding of the underlying unity of all human experience.⁵⁷

Why should an occupational therapist know about this evolving social phenomenon—disability culture? Is our contribution so bound to a medical model that we cannot acknowledge this cultural expression? What value is our relationship with those who have disabilities if not to support participation in all aspects of occupation, including those expressing a disability cultural perspective?

Design and Disability

Bickenbach, a disability rights law and policy maker, has drawn on Irving Zola’s work,¹² reminding us that the “special needs” approach to disability is inevitably short-sighted. If we see the mismatch between impairments and the social, attitudinal, architectural, medical, economic, and political environment as merely a problem facing the individual with a disability, then we are ignoring that disability

is an essential feature of the human condition. It is not whether a disability will occur, but when; not so much which one, but how many and in what combination. The entire population is at risk for the impairments associated with chronic illness and disability. As people live longer, the incidence of disability increases. Viewing disability as an abnormality does not provide a realistic picture of the human experience. Bickenback, in his discussion of disability as a human rights issue, underlined the fact that disability is a constant and fundamental part of human experience and that no individual has a perfect set of abilities for all contexts; there are no fixed boundaries dividing all the variations in human abilities. Our usual description of contrast between ability and disability is, in fact, a continuum of functionality in various settings.¹²

This perspective impacts the occupational therapy role in the realm of assistive technology and modification of the environment to enhance individual performance of occupational behavior. Our literature is overflowing with discussions about assistive technology (see Chapter 17) and environmental modifications: applications with various diagnostic classifications, methods for training one on the use of assistive technology, the usefulness of providing a specialized device to enhance performance, and home modifications. The concept of universal design (the way the environment may be designed to support individual differences) is not as prominent in our professional literature. This idea includes the built environment, information technology, and consumer products, as well as a host of commercial and social transactions, usable by all people, to the greatest extent possible, without the need for adaptation or specialized design. The concept is thus: if devices (buildings, computers, educational services, etc.) are designed with the needs of people with disabilities in mind, they will be more usable for all users, with or without disabilities.

Disability is just one of many characteristics that an individual might possess that should influence the design of our environments. An example of universal design is ramped entries, which are required by federal law (Americans with Disabilities Act Accessibility Guidelines [ADAAG]) regulations in public buildings (including transportation services such as airports and train stations) and designed for those who use wheelchairs. As that design requirement has become increasingly implemented, the pervasive use of wheeled luggage by all travelers, as well as parents pushing children in strollers and delivery staff with rolling carts, has become commonplace. Just imagine the impact on home modification if new housing construction design included the requirement for one entrance easily adaptable and a bathroom door wide enough for wheelchair access.

Activists from the independent living movement influenced the fledgling personal computer revolution to integrate a multitude of individual preferences from the size and type of the font to the ease with which adaptive technologies such as speech recognition and alternative keyboards interact with operating systems. Universal design of instruction

is evident as educators are increasingly trained to include multiple modalities of visual, auditory, and tactile systems to address the needs of people with wide differences in their abilities to see, hear, speak, move, read, write, understand English, attend, organize, engage, and remember.¹⁶

It is argued that universal design principles could make assistive technology unnecessary in many situations involving an impairment. A can opener that has been designed for one-handed use by anyone busy preparing multiple steps in a recipe also will also be usable by the cook who has a CVA-caused hemiparesis impairment.

Universally designed devices and aids may be one remedy for the stigmatization attached to special equipment. We know from research with older persons that “potential usefulness of a device is often offset in the minds of clients by concerns about social acceptability and aesthetics.”²² There will always be a need for individually prescribed equipment because impairments and individual needs are associated with so many variations of disability.

Interactional Process: The Person with a Disability and the Environment

International Classification of Functioning, Disability, and Health

In 2001, the World Health Organization (WHO) restructured its classification (the International Classification of Functioning, Disability, and Health, known as ICF) of health and health-related domains that describe body functions and structures, activities, and participation. The domains are classified from body, individual, and societal perspectives. The ICF also includes a list of environmental factors, because the individual performs within a context. The aim of the ICF classification is to provide a unified and standard language and framework to describe changes in body function and structure, what a person with a health condition can do in a standard environment (the person’s level of capacity), as well as what the person actually does in his or her usual environment (the person’s level of performance). The text produced with the language will depend on the users, their creativity, and their scientific orientation. This document is a companion to WHO’s International Classification of Disease, Tenth Revision (ICD-10).⁸⁵ For health practitioners, including occupational therapists, the ICF challenges mainstream ideas on how health and disability are understood.

The ICF stresses health and functioning, rather than disability. Abandoned is the notion that disability begins at the point where health ends. The ICF is a tool for measuring the act of functioning, without regard for the etiology of the impairment. This radical shift emphasizes the person’s level of health, not the individual disability.⁸⁶

Fougeyrollas and Beauregard pointed out that the revision of the ICF is more aligned with social ecology’s theoretical description of disability and is distanced from reductionist

social theory by emphasizing the role of environmental factors. It is also more in accord with the disability rights movement.²⁸ The revised OTPF—Occupational Therapy Practice Framework: Domain and Process, second edition—uses the ICF terminology to enhance communication with other healthcare areas.^{4,34} Disciplines such as ergonomics and occupational therapy consider the environment to be an essential component of human behavior. To illustrate this shift in thinking, social ecologists point particularly to models of human occupation used in occupational therapy, such as the ecology of human performance,²⁵ the human occupation model,⁴⁰ and the person-environment-occupational model.⁴⁶ Occupational therapy theory development has had significant influence in changing the paradigm used in rehabilitation by applying holistic and ecological principles to an understanding of the human condition.²⁸

Historically, occupational therapy has been associated with the field of medicine and its emphasis on etiology, or causation, to explain function and disability. In contrast, our profession is presently building an understanding of occupation as a social construction. In keeping consistent with a social model of disability, our focus on occupation produces an “understanding of people for who they are, have come to be, and are in the process of becoming.”⁵⁹

Health, as defined by the WHO, is a state of physical, mental, and social well-being. It is the capacity of the individual to function optimally within his or her environment or the adaptation of the person to his or her environment or setting.²⁸ The ICF moved away from being “a consequences of disease” classification in 1980 to become instead a “components of health” classification. Components of health identify the constituents of health (Table 6-1), whereas consequences of health focused on what may follow as a result of disease. This shifted from an exclusive view of

disability from the medical model, directly caused by disease, trauma, or other health conditions that require individual treatment by professionals, to a paradigm that allows for integration of a social model, where disability is not an attribute of an individual but rather a complex collection of conditions, many of which are created by the social environment (Box 6-5). The social model requires social action and is the collective responsibility of society at large to make the environmental modifications necessary for the full participation of people with disabilities in all areas of social life.⁸⁵

According to the WHO, neither the medical model nor the social model provides a complete picture of disability, although both are partially useful. The complex phenomenon called *disability* can be viewed at the level of a person’s body, as well as primarily viewed at the social level. It is always a dynamic exchange between the characteristics of the person and the overall context within which the person is operating, but some aspects of disability reside within the person (e.g., the cellular changes associated with a disease process), whereas other aspects are essentially external (e.g., fears and prejudice of others about the disease). Thus, both application of the medical and social model are appropriate. The best model of disability is one that synthesizes what is accurate in each model, without the exclusion of the other viewpoint. WHO proposes calling this the biopsychosocial model and has based the ICF on such a synthesis. The aim is an integration of the medical and the social to produce a coherent view of health, incorporating biologic, individual, and social perspectives.⁸⁶

The ICF allows for the real-world observation that two persons with the same disease can have different levels of functioning, and two persons with the same level of functioning do not necessarily have the same health problem (Table 6-2). Two individuals will generally have different

■ TABLE 6-1 | ICF Parts and Components

Part	Component
Functioning and disability	Body functions and structures Activities and participation
Contextual factors	Environmental factors Personal factors

■ Box 6-5

ICF Definition of Environmental Factors

- Products and technology
- Natural environment and human-made changes to environment
- Support and relationships
- Attitudes
- Services, systems, and policies

■ TABLE 6-2 | Example of ICF Terminology Usage

Health Condition	Impairment	Activity Limitation	Participation Restriction
Spinal injury	Paralysis	Incapable of using public transportation	Lack of accommodations in public transportation leads to no participation in religious activities
Bipolar illness	Cognitive and emotional dysfunction	Incapable of managing finances	Lack of credit leads to homelessness

environmental and personal factors interacting with distinct body function.

The shift from the medical model—namely, away from fixing a problem residing within the individual—to an integration in occupational therapy practice of the social model, which accounts for the interaction of the person and the environment, has led to evolving theoretical constructs.^{21,41} For example, the therapeutic notion of adaptation to environment, whereby individuals are expected to transform themselves through therapy, has been questioned by occupational science theorists. Rather, an interactional, dynamic, reciprocal adaptation of both the person and the environment emphasizes more the social model approach. Cutchin proposed the concept of place integration instead of adaptation to environment, whereby “people are more a part of their environment, and environments more a part of people,”²¹ with the person’s “motivations and processes never fully independent from the physical, social, and cultural realms that shape the self and desires.”²¹ In Cutchin’s conclusion, he underlined that client and practitioner are reflexive social selves, with the potential for “the therapeutic moment, one in which the client and therapist are united by place and social ties and by the collaborative effort to coordinate occupation so that person and place become once again integrated and whole.”²¹

A Canadian study of women wheelchair users underscored these evolving theoretical constructs. The researchers concluded that the barriers these women experienced were a lack of space, stairs, difficult to reach spaces, poor transportation, and limited community access. The study recognized the importance of the many strategies the women used to regain control over their environment and to attain autonomy and participation in the community. The researchers call on clinicians to have sensitivity to the meaning of home by including the relationship between body and environmental features that surround that meaning.⁶⁵

Swedish researchers, Lexell, Lund, and Iwarsson, studying people with multiple sclerosis (MS), similarly concluded that professionals need to broaden their repertoire to address the social conditions that influence meaningful occupations. They described the way those with MS in their study claimed they were forced to prioritize the most necessary occupations over the most desired occupations and those that could be conducted at any time over those that needed to be preplanned. Planning and addressing the balance of occupations over time is a more complex situation than previously recognized. Moreover, because planning and balance of occupations over time seems so strongly influenced by other people, interventions must be aimed not only at the client but also at other people involved in the client’s occupational engagement.⁵¹

Relationship between the OT and the Person with a Disability

Nancy Mairs’s account of her experience with multiple sclerosis in the case study at the beginning of the chapter does not describe her relationships with medical or rehabilitation

specialists. One might assume that, at times, there were reasons for her to seek advice, treatment, or consultation with such professionals. The determination of a diagnosis with multiple sclerosis can be a long and arduous journey fraught with miscalculations, multiple speculations of cause, and little of the support one might expect in other aspects of medical rehabilitation, when there is a distinct, sudden onset or trauma.

Ethical Considerations

The need for professional healthcare consultation is generally not a choice; rather, the need arises from trauma or a more insidious dysfunction impacting an individual’s well-being. Healthcare providers must honor the vulnerability of those who engage us in their quest for restored well-being. Care and thoughtfulness must prevail to ensure respect, dignity, and ethical responsibility with those who engage occupational therapy.

Occupational therapy values center on a humanistic concern for the individual,⁵⁹ particularly individuals who have a chronic, severe, and lifelong disability and who will never be cured.⁸⁹ Some occupational therapy practitioners may be engaged by a person with a temporary disability (e.g., an injury to the hand that gains most or even all of its former function) or work in prevention programs designed to reduce work injuries and do not have contact with those who are considered disabled. However, most people served by occupational therapists have lifelong conditions that cannot be “cured”⁶⁶ and, therefore, most of those served do not escape the potential for devaluation, stigma, liminality, stereotyping, and the experience of a world designed primarily for those without their differences. Some will have differences that are not observable in casual contact—for example, those with autoimmune deficiencies, seizure disorders, pain, or heart and pulmonary dysfunctions—and yet, once discovered or disclosed by others, produce similar personal and social results.

Rather than eradicating disease, occupational therapists identify and strengthen the healthy aspects or potential of the person. Self-directedness and self-responsibility of the person are emphasized rather than compliance or adherence to orders. A generalist, integrated view of the person as one who interacts with his or her environment guides OT practice rather than a specialist, reductive perspective. This integration requires emphasis on daily life activities and engagement in the occupations expected by the culture. The therapeutic relationships of occupational therapists should be based on mutual cooperation⁷² rather than an active therapist and passive patient approach. The recipient of our service should be viewed as an agent or actor with goals, interests, and motives and not as one whose behavior is

determined by merely physical laws;⁵⁰ rather, we possess faith in potential ability, actualized by engagement in activity. The recipient's productivity and participation, rather than relief from responsibility, are emphasized.

OT Practice Notes

Occupational therapists seek to facilitate a balance among performance in areas of occupation³ such as work, rest, play, sleep, ADLs, and a restored sense of well-being. To accomplish this goal, the occupational therapist must understand the individual's experience and point of view, instead of relying on observation as the only credible source of information.

Although many occupational therapists provide services in a medical model milieu, we view the client in a way that is different from the traditional medical perspective of diagnosis, cure, and recovery and should follow a different thought process. Our concern with the capacity to engage in daily life activities means that our scope of practice must include not only the hospital setting but also home and community. Thus, occupational therapy may practice both within and outside of the medical milieu, often helping clients to become agents in their own return to health and well-being. In this sense, OT practice bridges the sometimes alien world of acute medical care with engagement in the world of home, family, and culture.

Therapist as an Environmental Factor

OTs and other rehabilitation professionals are a distinct part of the social context for those with disabilities; OTs are an environmental factor for an individual as he or she seeks a sense of well-being. Behaviors, beliefs, and demonstrated attitudes have a bearing on the lived experience of the person OTs seek to serve. OTs bring to the environment cultural biases (e.g., woman as homemaker, man as breadwinner), religious beliefs (e.g., illness as a manifestation of sin or divine intervention), and attitudes toward disability and disablement (e.g., the mass media stereotypes). Personal mindset may be in conflict with the desire for an authentic understanding of each individual; for example, Asch, discussing bioethics, reported that "Rehabilitation specialists ... dramatically underestimate life satisfaction of people with disabilities, regardless of the length of time they had been in the field or the number of people they had worked with."⁷ It is reasonable to conclude that such an underestimate impacts the quality of the interaction between the person served and the specialist, and that it must influence the social context of the relationship.

Basnett,¹⁰ a physician with a cervical spinal cord injury, argued that the predominant influences on healthcare professionals and their attitudes are the norms of society. Often reinforced by training and practice and biased

predominantly by seeing disabled people when they are sick, health professionals can develop a view of disability that is at substantial variance from its reality for many disabled people. This can affect vital decisions involving health professionals that affect disabled people. His research results included (1) general health professionals' attitudes, in which attitudes become more negative as professional education proceeds, (2) a power imbalance in the relationship between the professional and the patient, and (3) functional limitations and the differences of disabled people are highlighted, rather than contacts emphasizing the strengths and similarities. He noted that other professionals, such as occupational therapists who specialize more in disability and varying functional limitations, may develop a different view than physicians.

Wright observed that the goals of rehabilitation, independence, and self-directedness must be nurtured during rehabilitation.⁸⁷ She proposed that co-management could result in improved outcomes. She observed that helping relationships might get in the way by conveying subservience and less power for the person being helped and by reinforcing the view that the expert has or should have the answers. The client might expect and want the professional to take complete charge. In some circumstances, such as acute medical care, this approach is necessary and commendable. However, shifting responsibility and power to the therapist can interfere substantially with the goals of rehabilitation and OT, especially the goal of independent living. Wright, therefore, asserted that "It is essential that the client be brought into a directorship role as soon as [is] feasible."⁸⁷ Similarly, one of Guidetti, Asaba, and Tham's central research findings, "therapeutic relationship as enabling possibility," underscores this conclusion with self-care intervention.³³

Wright also acknowledged that rehabilitation specialists may have needs that interfere with co-management.⁸⁷ They might need to assert themselves, display their knowledge, gain power, or achieve satisfaction in an authoritative role. Wright also cited the increasing pressure for efficiency and cost containment in the system as a stumbling block because co-management may require more time and effort than would professional prescriptions. Her advice was, "Don't get stuck with the problem; move on to the solution" to prod constructive thinking.

Research supported the findings about long-term effects of co-management.⁸⁷ A group of 100 patients with severe disability underwent rehabilitation in a hospital that encouraged their maximum involvement and participation. One year after discharge, their status was compared with that of a control group that had completed a conventional rehabilitation program at the same hospital. The experimental group showed a greater degree of sustained improvement in self-care and ambulation and a lower mortality rate.

Wright concluded with the conviction that, whenever feasible, co-management on the part of the client should be promoted.⁸⁷ The therapist should support this belief

by showing that he or she respects the patient, by being friendly and caring, and by showing concern about the patient's overall welfare. Basic social civilities such as knocking at the door of the hospital room, introducing oneself, and addressing the recipient of services by name are important. The professional needs "to question at all times whether the client is at the helm" or whether the person is being "paternalistically directed." This last test is especially important for occupational therapists who may work in an environment in which professional authoritarianism is the norm.

Therapeutic Use of Self

Gill stated that even though there are negative depictions in the literature, many people with disabilities have commendable relationships with nondisabled family members, friends, intimate partners, health professionals, and employers, relationships that, in fact, promote health.³¹ She reports that many individuals with disabilities have descriptive narratives of their lives in which key nondisabled persons are themselves without disability prejudice, are aware of prejudice when it appears, and are allied in despising it. These allies appear to learn who their disabled associates are in their "full glory and their full ordinariness."³¹

Neville-Jan,⁵⁸ an occupational therapist and professor with spina bifida, in her autoethnography of the "world of pain," described how an authentic and respectful relationship may be created. She referred back to Yerxa's 1967 Eleanor Clarke Slagle lecture and reminds us that "authentic occupational therapy implies a commitment to a patient's meaning system and a relationship that is best described as 'being there' with our patients."⁵⁸ Quoting Clark, Ennever, and Richardson, she stated, "Techniques of collaboration, building empathy, inclusion of the ordinary, listening, and reflection²⁰ are important for understanding patients' stories of their world of occupation, and, thereby, developing trust and hope." Neville-Jan stated:

In my story there were two professionals who engendered trust and hope consistently whether treatment worked or not. We were partners; they listened and shared stories from their lives, their families, and their interests. They were empathetic listeners. ... They were not rushed or impatient as I told them about my daily struggles with pain. They didn't try to change the topic to one that was not pain-related.⁵⁸

Darragh et al., from their research with participants with brain injury, described similar qualities and traits necessary for the positive perception of treatment.²²

Neville-Jan's account of the authentic practitioner's behavior contrasts discernibly with Vash and Crewe's description of devaluation: disdain for a lesser, inferior being, seen as incapable, not useful, probably a burden, unattractive, and of a lower status.⁸² The call for the authentic practitioner is for one who does not devalue the individual with a disability.

Another professor, Smith, in the field of education, who also has a disability, calls for a relationship of ally, joined with another for a common purpose; a person who respects, values, and supports, in a collaborative manner, the goals and aspirations of another, with knowledge that that person may speak and act on his or her own behalf. It's not the same as the advocate who speaks for another or presumes to know what the other wants or needs.⁷⁵ In the words of Yerxa, "Formulating wise questions requires establishing a partnership with those we wish to serve" and "we need to understand [the] relationship [of routines of daily life] to both personal goals and the environment as seen through the eyes of the individual."⁹⁰

Client-Centered Practice: A Shift From the Medical to the Social Model

Client-centered practice has gained importance over the past 20 years. Occupational therapists consider it necessary to have a partnership with the client, one in which the client identifies issues to be addressed and collaborates in the selection and implementation of interventions. Adoption of this approach coincides with more therapists working in settings that expect a client-centered practice: schools, independent living centers, community settings, and health promotion centers.⁴⁸

Chuck Close, a highly regarded visual artist, was interviewed several years after his successful return to the competitive world of art after extensive rehabilitation for a collapsed spinal artery, which left him almost completely paralyzed. A brace device on his partially mobile hand, a sophisticated wheelchair, and other aids allow him to paint. He rightfully criticized the attempts by therapists to engage him in housekeeping tasks when engagement in art and art creation was the defining occupation of his being and continues to be, despite his physical limitations. Finding a few paints and a way to make marks with paint in the basement of the rehabilitation center was the turning point of his "recovery."²⁹

Occupational therapists working in rehabilitation centers frequently place much more emphasis on technical goals (such as range of motion and muscle strengthening) than on the skills needed for independent living.⁶⁰ Independent living skills require the OT to include a client's participation in preferred occupations, which involves not only the environment in which these occupations take place but the socialization that supports engagement in these occupations. Occupational therapists should devote more time and energy to preparing patients for the capacity to function in their own communities.⁶⁰

Lyons, Phipps, and Berro,⁵² occupational therapy practitioners in a major rehabilitation center, noted that the "shift from the medical model which encourages the client to take responsibility for making decisions" about the course of treatment, presents a unique opportunity for OTs to return to a more authentic, occupation-based approach to practice and to rediscover their roots

in client-centered practice. They extol the virtue of their reinvention of practice to a truly client-centered and occupation-based approach within a medical model setting, thereby declaring occupational therapy's unique approach to client care and positioning their leadership in client-centered care on the rehabilitation team. Their methods for achieving such a focus include use of a semistructured occupational performance questionnaire, the Canadian Occupational Performance Measure (COPM),⁴⁵ an occupational story-telling and story-making narrative designed to better know the client, and occupational kits to engage clients in occupations of their choice, such as gardening, letter writing, pet care, fishing, scrapbooking, and car care. The reinvention of practice, to return to an authentic, occupation-based approach is a win for the profession and a win for those we hope to serve.

Occupational therapists can help redefine disability.⁶⁸ This redefinition would include working for changes in social attitudes and practices so that society would recognize the dignity and worth of people with disability, granting their rights to self-definition and self-direction. The occupational therapist would strive to work in (social model) as a consultant, helper, and advocate, rather than as a diagnostician or a prescriber and manager of treatment. "The consumer is or becomes self-directed, and both the consumer and occupational therapist work to remove community barriers and disincentives"⁶⁸ for economic independence.

Life Satisfaction and Quality of Life

The concepts of life satisfaction and quality of life are very important when discussing the personal and social context of physical disabilities.⁶¹ Life satisfaction is considered to be the subjective component of an individual's overall quality of life.⁸¹ How satisfied an individual is with his or her life may include such factors as satisfaction with family life, engagement in leisure activities, vocational pursuits, self-care, and sexual expression. Satisfaction does not require the same level of participation from each individual, but instead reflects the person's value regarding his or her level of participation in various life situations. A preponderance of the literature regarding psychosocial issues of physical disability for those with a variety of chronic disabling conditions (whether acute, progressive, or congenital onset) describes using an individual's perceived quality of life or life satisfaction as a measure of the person's success in adapting to or overcoming the emotional consequences of these diagnoses. Self-reported absence of depression, anxiety, and suicidal ideation are deemed evidence of mental health, which is frequently equated with high quality of life and life satisfaction.^{39,78}

Of particular relevance to occupational therapy is what clients report as contributing to their quality of life and life satisfaction. In the early 1980s, Burnett and Yerxa found that individuals with disability, while satisfied with their

performance of personal ADLs after discharge from rehabilitation, felt ill prepared for functioning in the home and community.¹⁷ More recent studies indicate that those individuals with disability who report high quality of life and life satisfaction regarded socialization (friendship), leisure, and productive occupations as most responsible for their reported high quality of life and life satisfaction. In fact, for the four participants in Pendleton's qualitative study of the friendships of successful women with physical disability, friendship-supported participation in occupation, and participation in occupation, in turn, facilitated their friendship.⁶¹

Studies in Sweden showed that among community-based people who had had strokes, life satisfaction was not correlated with the degree of physical impairment. Rather, it was related to people's ability to achieve their own valued goals.¹³

Summary

This chapter explores the personal and social contexts of physical disability and implications for occupational therapists. The individual experiences of people with disabilities are necessary resources for practitioners to create a meaningful and useful approach to the problems of living with disability.

Distinctions between the medical model and the social model and its sister, the independent living philosophy, as applied to the experience of disability, give us important lessons for creating useful relationships with those who may benefit from our professional knowledge and skills. As we explore engagement in a unique pattern of occupations, in unique environments with individuals who have specific interests, we seek to improve the potential satisfaction of that experience for that individual. Our attention must include the removal of barriers to that engagement in occupations.

Using our professional expertise, we practitioners, become an integral part of a client's environment through our direct contact and construction of a rehabilitation (or health promotion) environment along with other professionals. We are held by the ethical standards and the mission of our profession to foster relationships that promote quality of life and personal autonomy. The language we use conveys a powerful affective message and must reflect our values. As members of the larger society exposed to mass media images of disability, we may need to examine our own biases—namely, "handicapist" stereotypes—that create attitudinal barriers for those with disabilities.

Our commitment to improving the life opportunities of people with disabilities directs us to always strive for improvement in our practice and knowledge base. Our thoughtful desire for, and value of, positive change in the human condition must lead us to continual self-examination, throughout our individual careers.

Threaded Case Study | Nancy, Part 2

Nancy's account of the experience of living with MS was not written to form a relationship with an occupational therapy practitioner or, for that matter, any other professional. Rather, this insider's reflection was written, in the editor Fries' words, to "affirm our lives by putting the world on notice that we are staring back."³⁰ Fries quotes the question: "Who should have the power to define the identities of people with disabilities and to determine what it is they really need?" With that admonition, one should not be drawn into speculation based on her account about what Nancy may or may not find useful from a practitioner. We may, however, glimpse into a description of a type of cross-cultural identity, one with and without disability.

How does Nancy's view of herself as a "good-looking, even sexy, young woman" change as the MS progresses? One might consider that being a "good looking, even sexy, young woman" is an area of occupation that includes social participation, leisure, play, instrumental activities of daily living, and ADLs. The performance skills needed to engage in the occupation are numerous and, from Nancy's account, changed as the MS progressed. She elegantly describes mainstream cultural expectations regarding the correct expression of the occupation. Luckily, her social environment includes "a husband with a strong libido and a weak sense of social propriety."

What impairment-based difficulties and the participation restrictions are described? Nancy describes several

impairment-based difficulties: "pernicious fatigue that had begun to devour me, 'foot drop,' limp, timid gait, loss of muscle tone, as well as 'disruptions ... excretory functions.'" The participation restrictions described include social reactions to a cane, leg brace, a three-wheeled scooter. "I'm not by their standards, quite a person anymore," and with reference to sexuality, "you can hardly get a doctor, let alone a member of the general population, to consider the issues it raises."

How do you explain her use of language in referring to disability, particularly her use of the word "cripples"? As with others who identify with a minority group, especially a group historically referred to by a pejorative, such as "cripples," Nancy may be evoking her right to use the word from an insider's point of view. This turning of tables through the use of highly charged language can be viewed as a rite of passage as a minority group member develops a sense of pride and cultural identity. Switzer pointed out that "just as the civil rights movements for people of color raised questions about the propriety of terms such as 'Chicano' and 'Afro-American,' those in disability activism are not in agreement among themselves about terminology. ... The more militant activists have called for a return to the stereotypical terminology of prior centuries [such as] 'cripple.'"⁷⁷

Review Questions

1. How would a therapist approach a clinical situation if employing an independent living movement philosophy? In what ways does the approach differ from traditional treatment?
2. What are some of the individual elements that affect the personal context of the disability experience?
3. What do we know about stage models of disability adaptation? In what ways are they useful?
4. How do stigma, stereotypes, liminality, and spread influence the social context of disability?
5. What are innovative ways of conceptualizing disability, culture, and the environment?
6. In what ways does the WHO ICF promote a biopsychosocial model of disability? How has this model gained support from occupational therapy theorists?
7. In what ways does the occupational therapist become an environmental factor with the person who has a disability?
8. What is the therapeutic use of self and why is it important?
9. How can practice become occupation centered and client centered?
10. What do we know about quality of life and life satisfaction with those who have disabilities?

Teaching Activities in Occupational Therapy

7

PAMELA RICHARDSON

■ Chapter Outline

Why occupational therapists teach activities

Phases of learning

Learning capacities

Procedural and declarative learning

Principles of teaching and learning in OT

Identify a meaningful activity

Choose instructional mode compatible with client's cognition

Structure the learning environment

Provide reinforcement and grading of activities

Structure feedback and practice

Help client develop self-awareness and self-monitoring skills

Factors that influence the learning process

■ Key Terms

Transfer of learning

Procedural learning

Declarative learning

Verbal instruction

Visual instruction

Somatosensory instruction

Intrinsic feedback

Extrinsic feedback

Contextual interference

Blocked practice

Random practice

Metacognition

Strategies

■ Learning Objectives *After studying this chapter, the student or practitioner will be able to do the following:*

1. Discuss specific outcome goals for which occupational therapists teach activities.
2. Analyze how therapeutic interventions will differ, depending on the types of learning processes a client needs to develop.
3. Apply to occupational therapy interventions current knowledge about factors that influence motivation and active participation.
4. Provide appropriate instruction, feedback, and practice tailored to individual tasks and client goals.
5. Promote transfer of learning to real-life situations through effective approaches to teaching activity.
6. Implement occupational therapy interventions designed to promote active strategy development.

Case Study

Li

Li is a 67-year-old retired high school science teacher who was hit by a car as he walked across a city street. Before his accident, he was active in a variety of volunteer activities that included teaching English as a second language at the local adult education program, working as a docent at the local botanical gardens, and leading nature hikes in a nearby county park. He also was an amateur watercolor artist who had recently begun to receive recognition for his landscape paintings.

Upon referral to occupational therapy, he was nonambulatory because of a fracture of the pelvis and right femur. He also had fractures of his right clavicle and humerus, and multiple fractures of his dominant right forearm and hand. He had a severe concussion and experienced dizziness and impaired balance, memory loss and confusion, and episodes of agitation.

Critical Thinking Questions

1. What types of activities should Li learn how to do? Should the activities/tasks be related to an occupation?
2. What **strategies** should Li's therapist use to facilitate his learning?

Teaching is a fundamental skill for occupational therapists. Therapists spend much of their time with clients teaching a variety of activities. Effectiveness as a teacher depends on the therapist's ability to organize the environment and the instructional methods to meet the learning needs of the individual client. This chapter discusses the process of teaching for occupational therapists working with clients who have physical disabilities, and presents the reasons why occupational therapists teach activities, the phases and types of learning, and principles of teaching and learning with this population.

Why Occupational Therapists Teach Activities

Occupational therapists use a variety of teaching techniques in their interventions. Occupational therapists engage in teaching activities for the following reasons:

1. *To help clients relearn skills that have been lost as a result of illness or injury.* Clients may need to relearn how to perform daily tasks such as eating and dressing. They may also need to relearn basic performance skills such as the ability to maintain sitting or standing balance, reaching, or grasping. In the case of Li, his head injury affected both short- and long-term memory, impairing his ability to perform self-care skills. One of the first goals of his

OT program was to relearn hygiene and grooming skills so that he could regain independence in this aspect of self-care.

2. *To develop alternative or compensatory strategies for performing valued activities or occupations.* Clients may need to be taught new ways to perform familiar activities. Alternative or compensatory strategies can also be taught to prevent injury and increase safety. These strategies may be temporary, as in the case of an individual who needs to learn hip precautions after hip replacement surgery, or permanent, as in the case of an individual who needs to learn to use a tenodesis grasp after a complete spinal cord injury at the C6 level. In some cases, adaptive equipment may be needed to achieve independence, and instruction in the use of adaptive equipment must be included in the teaching of compensatory strategies. Li's occupational therapist instructed him in adaptive dressing and bathing techniques so that he could maintain independence in these activities while his fractures healed.
3. *To develop new performance skills to support role performance in the context of a disabling condition.* In some cases, clients will need to learn new skills to enable participation in daily occupations. Driving a wheelchair, operating a prosthetic device, and managing a bowel and bladder program are examples of new skills that clients with specific disabilities must learn. Li's therapist worked with him to develop a reminder system to compensate for his memory loss. He learned to record and keep important information with him in a small notebook so that he could easily access phone numbers, appointments, and other needed information.
4. *To provide therapeutic challenges that will help to improve performance skills to support participation in areas of occupation.* Therapists may teach clients activities that provide physical and/or cognitive challenges to facilitate the rehabilitation process. Activities such as board games and crafts can be used to improve strength, dexterity, postural control, and problem-solving and sequencing skills, among others. Clients may need to be instructed on the rules or procedures of the activity, as well as on how to position or organize themselves to engage in the activity. To improve dexterity in Li's injured right arm after the cast was removed, as well as to improve his attention and task orientation, his therapist instructed him in paint-by-number activities. These activities addressed his deficits in both motor and process skills, and supported his return to participation in his valued occupation of watercolor painting.
5. *To instruct family members or caregivers in activities that will enhance the client's independence and/or safety in daily occupations.* If the client is not able to learn to perform an activity using compensatory and/or

adaptive strategies, it is necessary to teach family members or caregivers how to assist or supervise the client in the activity. Many self-care and home activities may require assistance or supervision to ensure safety. Environmental modifications may need to be made to ensure the safety of the client and the caregiver and to facilitate maximal independence for the client. Li's wife was instructed on how to help him with wheelchair transfers. She was also instructed on how to cue him to use his reminder notebook at home.

Phases of Learning

Learning generally proceeds through three phases. These phases include the acquisition phase, the retention phase, and the generalization, or transfer, phase. The acquisition, or learning, phase that occurs during initial instruction and practice is often characterized by numerous errors of performance, as the learner develops strategies and schemata for how to successfully complete the task. The retention phase is demonstrated during subsequent sessions, when the learner demonstrates recall or retention of the task in a similar situation. **Transfer of learning**, or generalization of skill, is seen when the learner is able to spontaneously perform the task in different environments, such as the client who is able to correctly apply hip precautions at home after learning the precautions in the therapy clinic.

Learning Capacities

Not all clients are able to transfer skills learned in one environment into other contexts. Clients who cannot transfer learning will need environmental modifications, supervision, and/or cueing to engage successfully in the activity being taught. Therefore, the therapist needs to determine each client's capacity for retaining and transferring knowledge, so that therapist and client can establish appropriate goals and use appropriate teaching methods.

Dynamic assessment is one approach used to determine an individual's capacity to benefit from instruction. In this assessment framework, an interactive process is used whereby the therapist uses feedback, encouragement, and guidance to facilitate an individual's optimal performance using a test-teach-retest format.²⁷ Dynamic assessment complements more traditional assessment methods, giving therapists the opportunity to observe learning and change, which can help guide intervention.

Transfer of knowledge can be evaluated by changing one or more attributes of the task and observing whether the client is still able to perform the task. For instance, a therapist who has been teaching upper body dressing can change the type of garment used in the task, the location or orientation of the garment relative to the client, or the client's positioning. A client who is not able to perform the task

with one or more attributes changed may not be capable of transferring new skills.

OT Practice Note

Learning capacities can change dramatically in some clients because of spontaneous recovery from neurologic insults, so therapists should frequently reassess clients to determine whether teaching methods and goals need to be adjusted.

Procedural and Declarative Learning

Therapists teach tasks in which learning occurs both consciously and unconsciously. Knowledge is demonstrated in different ways for the two types of tasks. **Procedural learning** occurs for tasks that are typically performed automatically, without attention or conscious thought, such as many motor and perceptual skills. Procedural knowledge is developed through repeated practice in varying contexts. An individual learns to maneuver a wheelchair through a process of procedural learning, while gradually developing a movement schema for the activity.²⁴ **Verbal instruction** alone is of little value. Rather, the procedures for performing this activity are learned through opportunities to experiment with different combinations of arm or arm and leg movements to achieve propulsion in a variety of directions and speeds. Learning is expressed through performance; therefore, individuals who have limitations in cognition or language can still demonstrate procedural knowledge.

Declarative learning creates knowledge that can be cognitively recalled. Learning a multistep activity such as tying a shoelace or performing a transfer is often facilitated if the client can verbalize the steps of the task while completing it. Learning can also be demonstrated by verbally describing (declaring) the steps involved in completing the activity. Through repetition of an activity, declarative knowledge can become procedural, as the movement becomes more automatic and requires less cognitive attention. Mental rehearsal is an effective technique for enhancing declarative learning. During mental rehearsal, the individual practices the activity sequence by reviewing it mentally or by verbalizing the process. This method can be used effectively with clients who because of weakness or fatigue are limited in their ability to physically practice an activity. However, because of the cognitive requirements, clients with significant cognitive or language deficits may not be able to express declarative knowledge.

Principles of Teaching and Learning in OT

The process of teaching activities involves a sequence of clinical reasoning decisions. Regardless of the characteristics of the client and the activity, basic learning principles can

Box 7-1

Principles of Teaching and Learning in Occupational Therapy

- Identify an activity that has meaning or value to the client and/or family.
- Choose an instructional mode that is compatible with the client's cognition and the characteristics of the task to be taught.
- Organize the learning environment.
- Provide reinforcement and grading of activities.
- Structure feedback and practice schedules.
- Help client develop self-awareness and self-monitoring skills.

be applied to any teaching and learning situation. These principles are presented in Box 7-1.

The principles listed in Box 7-1 illustrate that before initiating a teaching activity, the occupational therapist must be aware of (1) the client's cognitive capacity, (2) occupations that have value to the client and the family, (3) the attributes of the task being taught, and (4) the context in which the client will be expected to perform the activity after discharge from therapy. The therapist needs to gather this information during the initial assessment to create an accurate knowledge base from which to develop the intervention plan, the choice of activities, and the method of teaching. Effective intervention requires appropriate, evidence-based application of these principles to each client's unique situation. Two examples of this include the framework of occupational gradation and goal-directed training. The framework of occupational gradation is a method of systematically manipulating properties of the task, the person, the object, and the environment to optimally challenge an individual's functional performance, specifically in terms of upper extremity motor skills. This framework incorporates principles of motor learning, motor control, personal factors, environmental factors, and properties of tasks and objects. Meaningfulness of the task, client goals, and ability to incorporate the task into daily life are also key considerations.²¹ The goal-directed training approach uses client-selected goals to create active problem-solving opportunities for the client. Intervention is focused on the task to be achieved, rather than on impairments that may limit performance. This approach is based on the dynamical systems models of motor control and motor learning, and the ecologic occupation-based models of intervention. Goal attainment scaling is used to measure progress.¹⁶ Each of these approaches combines occupation-centered activities and active engagement of the client with application of specific motor learning and teaching techniques tailored to the cognitive and motor abilities of the client. Procedural reasoning and narrative reasoning assist the therapist in determining the appropriate configuration of goals, activities, and teaching methods for each

individual. The principles of teaching and learning in occupational therapy are further discussed in the following sections.

Identify a Meaningful Activity

When conducting a client-centered assessment, the therapist explores which occupations have the greatest value and importance to the client. Engagement in these occupations can serve both as outcomes of intervention and as activities used in the intervention process. The client will be motivated to be an active partner in the therapy process if the activities are perceived to be meaningful.²⁸ If the client does not have the capability to engage in the occupation itself, performance skills and activities that contribute to participation in the occupation are often addressed in the intervention. The client needs to be informed of how developing or improving these skills will contribute to the ability to engage in the valued occupation. Doing so helps the client ascribe meaning to the activities and facilitates optimal participation.

Li's occupational therapist learned of his skill as a painter during the initial interview with Li and his wife. The therapist was able to use Li's motivation to return to this valued occupation to guide the choice of drawing and painting activities to improve function in his injured arm. The therapist also was able to explain to Li how his participation in other therapeutic activities to improve strength, range of motion, and endurance would contribute to his ability to resume his occupation of painting, as well as independence in daily living skills. The therapist's attention to Li's interests and values created trust that led to a productive learning partnership.⁶

Choose Instructional Mode Compatible With Client's Cognition

When many people think about the act of teaching, verbal instruction is what comes to mind. Verbal instruction is an effective means of conveying information in many situations. It is an efficient method for instructing groups, such as in back safety classes, during training in hip precautions after hip replacement surgery, and through instruction in body mechanics and ergonomic principles for employee groups. Verbal instruction can also be used effectively when instructing individual clients. Verbal cues can be used to provide reinforcement or to give information about the next step in the sequence or the quality of performance. Verbal cues can be an effective way to provide feedback in the early and middle stages of learning but, if possible, should be phased out as soon as possible so that the client does not become dependent on verbal cues to complete the task. Family members and caregivers can be instructed on how to provide appropriate verbal cues if the client is unable to recall a task sequence independently.

Visual instruction is effective for clients who have cognitive and/or attention deficits and difficulty processing

verbal language, as well as for tasks that are too complex to describe verbally. The therapist demonstrates the activity, and the client observes the therapist and follows the therapist's example. The therapist can repeat the demonstration as many times as is necessary for the client to accurately reproduce the task. The therapist can also break the task into steps, demonstrating one step at a time and continuing to the next step as the client completes the previous step. Other forms of visual instruction include drawings or photographs that can be used to remind a client and/or caregiver about the task sequence or desired performance outcome. Visual instruction can effectively be paired with verbal instruction, but therapists must avoid overwhelming the client with combined verbal and visual input.

Somatosensory instruction is a third mode of instruction. This involves the use of tactile, proprioceptive, and kinesthetic cues to help guide the speed and direction of a movement. Manual guidance is a form of somatosensory instruction that is especially effective for procedural learning, such as the process of weight shifting and postural adjustment involved in coming from sit to stand. Hand-over-hand assistance is effective in teaching activities to clients who have cognitive and/or sensory processing deficits; the therapist guides the client's hands in completion of a task.

Li's therapist used all three instructional modes. Verbal instruction was most effective for reteaching self-care skills; verbal cueing was used to orient Li to the task sequence during the acquisition phase of learning. Visual instruction was used to teach many of the therapeutic activities the therapist used to enhance upper extremity function. Somatosensory instruction was effective for balance retraining.

Structure the Learning Environment

Choosing the appropriate environment in which to instruct a client is critical to teaching success. If a client is confused or easily distracted, a quiet environment with minimal visual distraction is often needed when teaching of a task is begun. As the client becomes more proficient in the skill being taught, visual and auditory distractions need to be introduced, so that the environment more closely resembles the one in which the client will eventually engage in the activity. For instance, a therapist working with a client on self-feeding may initially conduct the intervention in the client's room. As the client becomes more proficient and confident, the therapist may move the intervention to the facility dining room, where multiple distractions are present. While providing challenges to the client's attention, the dining room also provides opportunities for social interaction, which may act as a motivator for the client to further improve self-feeding skills. Similarly, clients need opportunities to practice new skills in a variety of environments, so that they are proficient in meeting environmental challenges. A client who is learning how to control a wheelchair

needs to practice both outdoors and indoors on a variety of surfaces. A client who is working on refining grasp and dexterity needs experience in manipulating objects of a variety of sizes, shapes, and weights, while engaging in functional tasks with a variety of demands similar to those that will be encountered in the client's daily activities.

Li's therapist determined that his initial confusion and agitation necessitated a quiet, minimally stimulating environment for initiation of teaching in self-care skills. As Li's confusion cleared, he was able to work in the therapy clinic on activities to improve balance and upper extremity skills, and later worked in the kitchen and garden areas on more demanding and varied home skills.

Provide Reinforcement and Grading of Activities

The concept of reinforcement comes from operant conditioning theory, which states that behaviors that are rewarded or reinforced tend to be repeated.¹¹ Many types of reinforcement may be used. For some clients, social reinforcement such as a smile or verbal encouragement creates motivation to continue. Other clients may require more tangible rewards, such as rest periods, snacks, favorite activities, etc. Still other clients are motivated by visible indications of their progress. Use of a graph or chart to demonstrate daily improvement in performance skills or client factors such as grip strength, sitting tolerance, or range of motion can help a client to engage more actively in the therapy process. These are examples of extrinsic reinforcement.

Many clients are motivated by completion of a task, for instance, preparing a snack and then eating it, or dressing themselves independently so they can visit with friends. Completion of the task provides intrinsic reinforcement, seen in the individual's satisfaction in his or her ability to participate in desirable activities as a result of completing the task. An activity that is motivating and meaningful to the client can increase active participation and improve intervention outcomes.

Several studies have shown (1) that adding purposeful or imagery-based occupations to rote exercise results in more repetitions than are used for rote exercise alone,⁸ (2) that clients select occupationally embedded activities over rote exercise tasks,³¹ and (3) that added purpose occupations result in greater retention and transfer of motor learning than occur with rote exercise.⁵ Sietsema and colleagues²⁵ found that better scapular abduction and efficiency of forward reach were achieved when clients with traumatic brain injury focused on reaching to control a game panel than when they focused on how far they could reach an arm forward.²⁵ Similarly, Nelson and associates¹⁹ showed that intervention to improve coordinated forearm pronation-supination was more effective in stroke rehabilitation when clients focused on turning an adapted dice thrower in the context of a game than when they focused on the movement itself. Wu and coworkers²⁹ found that intervention to

improve symmetric posture in adults with hemiplegia had significantly better outcomes when subjects focused on wood sanding and bean bag toss games.

In addition to structuring the type of reinforcement, the therapist needs to carefully grade the challenges of the activity, so the client can experience success and mastery during the process of learning the activity. If the client has too much difficulty completing a task, social reinforcement or inherent meaningfulness of the activity will not be enough to override frustration or fatigue. Therefore, therapists must analyze the activity and determine how to grade the activity to meet the learning and reinforcement needs of the individual client. This includes deciding on the most appropriate mode of instruction as described in the previous section, what type of reinforcement will facilitate intrinsic motivation, and how best to structure feedback and practice schedules; these decisions are discussed in the next section.

Li's therapist knew that his strong desire to return to his occupation of leading nature hikes would motivate him to improve his balance and standing tolerance. The therapist explained how a variety of activities involving challenges to Li's sitting and standing balance would help him regain his postural stability. Li participated actively in these tasks and generated ideas for additional tasks that could be incorporated into his OT program; he also practiced outside of the therapy environment. His intrinsic motivation to perform these tasks in varied contexts was evident in his improved balance skills.

Structure Feedback and Practice

Feedback is information about a response²⁰ that can provide knowledge about the quality of the learner's performance or the results of the performance. **Intrinsic feedback** is generated by an individual's sensory systems. An individual learning to hit a golf ball uses visual and somatosensory feedback to evaluate performance. The visual system is used to align the head of the golf club and the golfer's body in correct orientation to the ball. Kinesthetic and proprioceptive inputs inform the golfer about joint position and the location of body segments in space; this allows the golfer to make the necessary postural adjustments and upper extremity movements to bring the club head into contact with the ball while using appropriate speed and force.

Extrinsic feedback is information from an outside source. The trajectory of the golf ball, the distance of the drive, and the location of the ball on the fairway all provide extrinsic feedback about the results of the golfer's actions. An observer can provide extrinsic feedback about task performance by giving the golfer information such as, "Your stance was too open," "You did not follow through far enough on the swing," or "Your head position was good." For clients whose sensory recognition or processing abilities have been impaired, extrinsic feedback from a therapist or technological device can provide useful supplementary

information to facilitate learning during the acquisition phase. Technological feedback mechanisms include biofeedback systems and digital displays of kinetic or cardiovascular data on exercise equipment. These feedback systems provide more immediate and consistent feedback than can be obtained from a therapist.

Although extrinsic feedback may be helpful early in the learning process, clients will achieve greater independence and efficiency in activities by developing the ability to continue learning through intrinsic rather than extrinsic feedback. In fact, extrinsic feedback may not produce optimal learning and may create dependency, with deterioration in performance if the feedback is removed.¹² Therefore, extrinsic feedback must be gradually decreased if the client's goal is independent performance in a variety of performance contexts.

Practice is a powerful component of the occupational therapy process. The ways in which a therapist structures practice conditions can influence a client's success in retention and transfer of learning. Several aspects of practice are discussed in the following paragraphs.

Li experienced mild sensory loss in his right arm as part of his injury. When his cast was removed and active rehabilitation commenced, he benefited from extrinsic verbal and somatosensory feedback provided by his therapist about the quality of his movement. As his upper extremity function improved, the therapist gradually decreased the amount of extrinsic feedback provided. Li learned to use intrinsic feedback to adjust the timing, speed, and direction of his movements while engaged in a variety of functional activities designed to improve strength, range of motion, and dexterity. Participation in practice sessions that included varied task challenges helped him to learn strategies that could be transferred to many activities.

Contextual Interference

Contextual interference refers to factors in the learning environment that increase the difficulty of initial learning. Limiting extrinsic feedback provided about the results of performance is one example of contextual interference. A therapist who is attempting to limit extrinsic feedback will minimize the amount of verbal feedback about performance and/or the amount of manual guidance provided during the task. Performance during the acquisition phase may be poorer with high contextual interference; retention and generalization are more effective. This may occur because a high level of contextual interference forces the learner to rely on intrinsic feedback and to adapt motor and cognitive strategies to complete the task, resulting in more effective learning.⁹

Blocked and Random Practice Schedules

Blocked and **random practice** schedules are examples of low and high contextual interference, respectively. During **blocked practice**, clients practice one task until they master it. This is followed by practice of a second task until it is

also mastered. In random practice, clients attempt multiple tasks or variations of a task before they have mastered any one of the tasks. A random practice schedule may be used to teach wheelchair transfer skills. The client practices each of several transfers during the course of a single session. For example, the client will practice moving between the wheelchair and a therapy mat, between the wheelchair and a chair, and between a toilet and the wheelchair. A random practice schedule for improving postural stability might include having the client stand on a variety of unstable surfaces such as an equilibrium board, a balance beam, or a foam cushion while playing a game of catch. These types of practice schedules may slow the initial acquisition of skills but are better for long-term retention of these skills²³ and for transfer of the learning to another context or task.⁷

Whole Versus Part Practice

Breaking a task into its component parts for teaching purposes is useful only if the task can naturally be divided into discrete, recognizable units.²⁹ This is so because continuous skills (or whole task performance) are easier to remember than discrete responses.²³ For example, once a person has learned to ride a bicycle, this motor skill will be retained even without practicing for many years. Continuous skills should be taught in their entirety rather than in segments. For example, the activity of making vegetable soup includes several discrete tasks, including chopping vegetables, measuring ingredients, assembling the ingredients in the soup pot, and cooking the ingredients. During one session, the therapist could teach a client to chop the vegetables; the other components of the task could be taught in subsequent sessions. However, for the activity of making a pot of coffee, the task components (measuring the water, pouring it into the coffeemaker, measuring the coffee, putting the coffee into the coffeemaker, turning on the coffeemaker) need to be completed in a specific order. Teaching any of these task components in isolation would not result in meaningful learning or independent activity performance. For best retention and generalization, making coffee should be taught as a complete task, rather than having the client practice a different portion of the task during each therapy session.

To facilitate the learning process, the therapist may provide demonstration, verbal cueing, or manual guidance as needed for selected aspects of the task. This way, the client experiences completion of the task on each trial, and the therapist gradually gives less assistance as practice sessions continue.

Cognitive Strategies

A growing body of literature supports the efficacy of cognitive strategies in helping individuals to learn motor skills. Cognitive strategies are goal-directed, consciously controlled processes that support motor learning and include memory, problem solving, mental imagery, perception, and **metacognition**.¹⁸ Cognitive strategies can be general or

specific. General strategies are used in a variety of situations, and specific strategies are used for a particular task. Evidence from a variety of studies suggests that cognitive strategies can assist individuals with stroke to transfer skills to different environments.^{13,14,18} Cognitive strategies can be used in conjunction with practice in variable contexts to facilitate learning of motor and functional performance skills.

Practice Contexts

Practice under variable contexts enhances transfer of learning. Optimal retention and transfer of motor skills occur when the practice context is natural, rather than simulated.^{15,17} This may reflect the fact that the enriched, natural environment provides more sources of feedback and information about performance than the more impoverished simulated environment. However, transfer of learning is better when the demands of the practice environment more closely resemble the demands of the environment in which the client will eventually be expected to perform.³⁰ Therefore, teaching kitchen skills in a client's own home or in a kitchen environment that is very similar to the client's kitchen will result in better task performance when the client engages in the task at home.

Client factors may also influence outcomes related to the practice context. A meta-analysis of the effects of context found that treatment effects were much greater for populations with neurologic impairments than for those without neurologic impairment.¹² Errorless learning is an intervention paradigm based on the principle that learning will occur more quickly and efficiently if the learner does not engage in trial and error throughout the learning process. This learning strategy has been used most frequently with individuals who have cognitive or memory deficits, but it has also been effective in facilitating learning of a practical skill (fitting a prosthetic limb) during the rehabilitation process.⁴

One aspect of the practice context that has received little research attention is the role of the social environment in task learning. The importance of the social context of occupational performance and of the occupation of social participation is endorsed by the Occupational Therapy Practice Framework-2.¹ Working with other clients in a group promotes socialization, cooperation, and competition, which can increase clients' motivation. Acquisition of skills is enhanced through observation of others who are learning a task. Additionally, group intervention can promote the development of problem-solving skills and can create a bridge between the supervised therapy environment and the unsupervised home environment.³

Help Client Develop Self-Awareness and Self-Monitoring Skills

To maximize the retention and transfer of learning, clients must develop the ability to self-monitor, so they are not dependent on extrinsic feedback and reinforcement. The

knowledge and regulation of personal cognitive processes and capacities is known as *metacognition*.¹⁰ It includes awareness of personal strengths and limitations and the ability to evaluate task difficulty, to plan ahead, to choose appropriate strategies, and to shift strategies in response to environmental cues. Although metacognition is typically discussed in relation to improving cognitive skills, self-awareness and monitoring of relevant performance skills may be equally important prerequisites to developing effective motor, interpersonal, and coping strategies. Specifically, an intervention directed toward helping clients develop enhanced awareness of body kinematics and alignment may be an important component of motor learning.³ Self-review of performance and guided planning for tackling the challenges of future tasks are key factors in the therapeutic process and are critical prerequisites to a person's ability to generate and apply appropriate strategies.

Strategies are organized plans or sets of rules that guide action in a variety of situations.²² Motor strategies include the repertoire of kinematic linkages and schemata that underlie the performance of skilled, efficient movement. The process of stepping to the side when one is abruptly jostled is a motor strategy for the maintenance of standing balance.²⁴ Cognitive strategies include the variety of tactics used to facilitate processing, storage, retrieval, and manipulation of information. Using a mnemonic device to remember a phone number is a cognitive strategy. Interpersonal strategies help in social interactions with other individuals. A person who uses direct eye contact and greets another by name when being introduced is using an interpersonal strategy. Coping strategies allow people to adapt constructively to stress. Coping strategies can include deep breathing, exercise, or relaxation activities.

Strategies provide individuals with foundational skills that can be adapted to the changing demands of occupational tasks within a variety of contexts. Thus, learning is more likely to be transferred to new situations when opportunities arise to develop foundational strategies.²⁶ Individuals develop strategies through a process of encountering problems, implementing solutions, and monitoring the effects of these solutions. Occupational therapists use activities to help clients develop useful strategies by presenting task challenges within a safe environment that provide opportunities to try out different solutions.²²

As Li was nearing discharge from occupational therapy services, the therapist worked with him to develop strategies to facilitate his occupational performance. Although his memory was improved, recall of names and numbers was still poor, so the cognitive strategy of using a notebook for recording important information was continued. In addition, to cope with persistent mild deficits in balance, Li and his therapist developed a motor strategy of keeping a sturdy table nearby when he stood to talk to visitors at the botanical gardens. This strategy provided a support that he could lean on or hold onto if needed and was a strategy that could be used in other situations as well.

Box 7-2

Factors That Support Transfer of Learning

- Active participation
- Occupationally embedded instruction
- Intrinsic feedback
- Contextual interference
- Random practice schedules
- Naturalistic contexts
- Whole task practice
- Strategy development

Factors That Influence the Learning Process

The ultimate goal of learning is to create strategies and skills that individuals can apply flexibly in a variety of contexts and occupations. As this chapter has presented, occupational therapists have many methods available to them to help their clients achieve this goal. The concepts discussed in this chapter that facilitate transfer of learning to other environments are listed in [Box 7-2](#).

Summary

Occupational therapists teach activities for a variety of reasons. They reteach familiar activities, teach alternate or compensatory strategies of performing valued activities, teach new performance skills to support role performance, teach therapeutic challenges to improve performance skills to support occupational participation, and teach caregivers and/or family members to facilitate client independence and safety in the home environment.

Occupational therapists use a variety of teaching strategies to promote skill acquisition, skill retention, and transfer of learning. Procedural and declarative learning represent unconscious and conscious learning processes, respectively.

Occupational therapists maximize the learning process by (1) identifying activities that have meaning or value to the client/family, (2) providing instruction tailored to the needs of the individual and the task, (3) structuring the environment to facilitate learning, (4) providing reinforcement and grading of activities to establish intrinsic motivation, (5) structuring feedback and practice to facilitate acquisition, retention, and transfer of learning, and (6) helping clients develop self-awareness and self-monitoring skills.

Review Questions

1. What is the difference between acquisition, retention, and transfer of learning? Apply these terms to describe the learning stages in a client you have observed.

2. When are declarative learning and procedural learning processes used? How will teaching methods differ when declarative or procedural processes are required?
3. What are the reasons why therapists teach activities? Give an example of desired teaching outcomes for each of the reasons presented in the chapter.
4. In which situations is extrinsic feedback valuable to the therapeutic process? What are some advantages and disadvantages of providing extrinsic feedback to clients?
5. Why does contextual interference contribute to transfer of learning? Think of an example of how contextual interference can be incorporated into an OT session.
6. Differentiate between random and blocked practice schedules. In which situations would each of these practice schedules be chosen?
7. Provide examples of how a therapist might structure whole practice versus part practice. In which situations might each of these types of practice be appropriate?
8. In which ways can occupational therapists enhance the variability of practice contexts? Give practical examples of how occupational therapists working in inpatient settings can provide treatment in natural contexts.
9. How can occupational therapists help clients develop metacognitive skills? Why are these skills important in the learning process?

Documentation of Occupational Therapy Services

8

JERILYN (GIGI) SMITH

■ Chapter Outline

Purposes of documentation
Best practices
Clinical reasoning skills
Clinical reasoning in documentation
Legal liability
Initial evaluation
Intervention plan
Progress reports
SOAP notes
Narrative notes
Descriptive notes
Progress checklists or flow sheets
RUMBA
SMART
Discharge reports
Types of documentation reporting formats
Confidentiality and documentation

■ Key Terms

Documentation	Occupational profile
Reimbursement	Long-term goal
Medical record	Short-term goal
Client record	SOAP notes
Legal document	Problem-oriented medical record (POMR)
Clinical reasoning	Checklist notes
Professional reasoning	Narrative notes
Initial evaluation report	Skilled interventions
Evaluation	Skilled services
Intervention plan	Medicare guidelines
Progress report	Confidentiality
Discharge report	Privacy
Occupational Therapy Practice Framework (OTPF-2)	HIPAA
Assessments	Ethical practice

■ Learning Objectives *After studying this chapter, the student or practitioner will be able to do the following:*

1. Identify five purposes of documentation.
2. Describe the basic technical points that should be adhered to when writing in the medical record.
3. Explain why only approved abbreviations should be used in occupational therapy documentation.
4. Describe the acceptable method of correcting an error in the medical record.
5. Explain why occupational therapy documentation should reflect the terminology outlined in the Occupational Therapy Practice Framework.
6. Describe the components of a well-written progress note.
7. Identify the different places where documentation is required.
8. Briefly summarize the content of the initial evaluation.
9. Define assessments as they apply to the occupational therapy process.
10. Describe the purpose of the intervention plan.
11. Explain why establishment of goals should be a collaborative effort between the client and the therapist.

■ Learning Objectives—cont'd

12. Explain the meaning of “client-centered goal.”
13. Describe the purpose of progress reports.
14. Explain what is meant by a skilled intervention.
15. List the components of a SOAP note and give an example of each component of the note.
16. Identify the purpose of the discharge report.
17. List the primary reimbursement systems of occupational therapy services in the physical disabilities setting.
18. Describe two ways that ensure that confidentiality in documentation is maintained (refer to the AOTA Code of Ethics and HIPAA regulations).

Threaded Case Study Jane, Part I

Jane just started her first job as an occupational therapist at a skilled nursing facility. This week she had to complete two initial **evaluations** and has seen four clients for therapy each day. Jane knows the importance of accurate **documentation**, and she wants to make sure that she includes data that will communicate the necessary information for **reimbursement**. She also knows that documentation is essential to demonstrate the value of occupational therapy. However, she has never worked in this practice setting and is worried about what terminology to use and how to effectively document to guarantee reimbursement.

Critical Thinking Questions

As you read this chapter, reflect upon the following questions as they pertain to the case study:

1. What specific skills must Jane employ as she decides upon how she will document the evaluation process?
2. What information is important to include in the SOAP note for reimbursement? Will the practice setting have an influence on what is included in the note?
3. How might the federal regulations (Health Insurance Portability and Accountability Act [**HIPAA**]) and the principles put forth in the Occupational Therapy Code of Ethics influence how Jane communicates the results of the occupational therapy evaluation and intervention program?

Documentation is an essential component of Occupational Therapy practice. It is the primary method of communication that is used to convey what was done with the client. It demonstrates to others the value of occupational therapy intervention.

Purposes of Documentation

Documentation is a permanent record of what occurred with the client. It is also a **legal document** and as such must follow the guidelines that will enable it to withstand a legal investigation. Reimbursement depends upon accurate, well-written documentation that provides the necessary information to justify the need for occupational therapy services.

AOTA has identified that the purposes of documentation are as follows:

- Articulate the rationale for provision of occupational therapy services and the relationship of this service to the client’s outcome
- Reflect the therapist’s **clinical reasoning** and professional judgment
- Communicate information about the client from the occupational therapy perspective
- Create a chronological record of client status, occupational therapy services provided to the client, and client outcomes¹

Clear, concise, accurate, and objective information is essential to communicate the occupational therapy process to others. The clinical record should provide sufficient facts to support the need for occupational therapy intervention.¹³

Documentation is required whenever occupational therapy services are performed. This includes a record of what occurred during direct client care, as well as supportive documentation required to justify the need for occupational therapy intervention.

OT Practice Note Examples of Documentation

Documentation is an ongoing process that continues throughout the client’s therapy program. Screening reports, **initial evaluation reports**, re-evaluation reports, progress notes, discharge summaries, other medical record entries (e.g., interdisciplinary care plans, MD telephone orders), intervention and equipment authorization requests, letters and reports to families and other health care professionals, and outcomes data collection are examples of places where occupational therapists document.

Best Practices

Regardless of where documentation takes place, several basic technical points are important to adhere to when writing in a **medical record**. **Box 8-1** lists the fundamental elements of documentation as set forth by the AOTA.² Proper grammar, correct spelling and syntax, and well-written sentences are essential components in any professional correspondence. Keeping lists of commonly used

■ Box 8-1

Fundamental Elements of Documentation

The following elements should be present in all documentation.

1. Client's full name and case number.
2. Date and type of occupational therapy contact.
3. Identification of type of documentation, agency, and department name.
4. Occupational therapy practitioner's signature with a minimum of first name or initial, last name, and professional designation.
5. When applicable on notes or reports, signature of the recorder directly at the end of the note and the signature.
6. Countersignature by an occupational therapist on documentation written by students and occupational therapy assistants when required by law or the facility.
7. Acceptable terminology defined within the boundaries of the setting.
8. Abbreviation usage as acceptable within the boundaries of the setting.
9. When no facility requirements are listed, errors corrected by drawing a single line through an error and initialing the correction (liquid correction fluid and erasures are not acceptable).
10. Adherence to professional standards of technology, when used to document occupational therapy services.
11. Disposal of records within law or agency requirements.
12. Compliance with confidentiality standards.
13. Compliance with agency or legal requirements of storage of records.

Date from American Occupational Therapy Association (AOTA): Guidelines to the occupational therapy code of ethics, *Am J Occup Ther* 60:652-658, 2006.

terms and using a hand-held spell-check device are two strategies that may assist with spelling difficulties. Poor grammar or inaccurate spelling can lead the reader to question the skills of the therapist. Legibility is important to ensure that misinterpretation does not occur. Only approved abbreviations are to be used in the medical record. All clinical sites should have a printed list of acceptable abbreviations that can be used at the site. It is important to obtain this list and use it as a reference when documenting. Examples of abbreviations commonly used in clinical practice are listed in Box 8-2. Misinterpretation of intended meaning can occur when unfamiliar abbreviations or casual language unsuitable for therapeutic context is used. Language particular to a profession (slang or jargon) should never be used in the **client record**.

All entries made into the medical record must be signed with the therapist's legal name. Your professional initials (OTR/L, OTL) should follow your signature. Do not leave blank spaces at the end of an intervention note. Instead, draw a single line that extends from the last word to the

signature. This prevents additional information from being added after the entry has been completed.

Ethical Considerations

Documentation must be written by the therapist providing the intervention. It is never acceptable to write a note for another therapist; in fact it is considered fraudulent to do so.

It is best practice to complete documentation as soon after the therapy session as possible. The longer the time interval between the evaluation or intervention and completion of the written record of the event, the greater the chance that details or other important information will be forgotten. Although documenting at the time of service delivery is ideal, it is not always possible. At these times, it may be beneficial for the therapist to carry a notepad or clipboard to record data that can later be included in the official write-up.

Altering, substituting, or deleting information from the client record should never take place.⁹ Changes made to the original documentation could be used to support allegations of tampering with the medical record, even when this was not the intent of the writer. However, at times, corrections must be made. Several principles should be followed to avoid questioning of the validity of the information. Never use correction fluid when correcting an entry in the client's record. An acceptable method of correcting an error in the documentation is to draw a single line through the word or words, initial and date the entry, and indicate that this was an "error." Do not try to obliterate the sentence or word, as this may appear to be an attempt to prevent others from knowing what was originally written. Late entries to the medical record cannot be backdated. If it is necessary to enter information that is out of sequence (e.g., a note that the therapist forgot to write), it must be entered into the medical record as a "late entry" and must be identified as such.⁹ Words or sentences cannot be squeezed into existing text "after the fact." Attempts to do this may be interpreted as adding missing information to support something that occurred after the original documentation was completed.

Ethical Considerations

Although no fraudulent intent may be present, it could be suspected if the content is ever called into question. Occupational therapy notes are legally binding and can be the best defense against a denial of reimbursement of services or a lawsuit.¹³

Do not leave blank spaces on evaluation and preprinted forms. If it is not appropriate to complete a section, "N/A"

Box 8-2

Abbreviations for Clinical Documentation

A:	assessment	PMH	past medical history
Add	adduction	post	posterior

can be inserted to indicate that the particular area was not addressed. If sections are left blank, others reading the chart may think these areas were overlooked.

Documentation should incorporate the terminology outlined in the **Occupational Therapy Practice Framework-2 (OTPF-2)**. One of the purposes of the OTPF-2 is to assist therapists in communicating to other professionals, consumers of services, and third party payers the unique focus of occupational therapy on occupation and daily life activities. Documentation should reflect the emphasis of occupational therapy on supporting function and performance in daily life activities and those factors that influence performance (performance skills, performance patterns, activity demands, client factors, context and

environment) during the evaluation and intervention process.⁴ Many practice settings that follow the medical model, such as hospitals, use the term *patient* to describe the recipient of services. Other settings may prefer the term *resident*. Although these are acceptable, the OTPF-2 advocates use of the term *client*. *Client* encompasses not only the individual receiving therapy, but also others who are involved in the person's life, such as spouse, parent, child, caregiver, employer, and larger groups such as organizations or communities. The OTPF-2 provides terminology that can be used at each stage of the therapy process. This will be explained in further detail when the various parts of the therapy evaluation, intervention, and discharge processes are described.

Clinical Reasoning Skills

Occupational therapists must use clinical or **professional reasoning** throughout the occupational therapy process. For the purposes of this chapter, the more contemporary term *professional reasoning* will be used instead of *clinical reasoning* when referring to the comprehensive types of thinking and judgment used by occupational therapists in making client-related decisions. Professional reasoning also includes determining how to appropriately document information obtained during the evaluation, intervention, and discharge process. Professional reasoning is used to plan, direct, perform, and reflect upon client care.¹⁹ Documentation must demonstrate that professional reasoning was used in the decision-making process during all aspects of the client's therapy program.

Professional reasoning (also referred to as clinical reasoning by some authors) comprises many different aspects of reasoning: scientific, diagnostic, procedural, narrative, pragmatic, ethical, interactive, and conditional.¹⁹ Scientific reasoning is used to help the therapist understand the client's impairments, disabilities, and performance contexts and to determine how these might influence occupational performance. Diagnostic reasoning is specifically concerned with clinical problem identification related to the client diagnosis. Procedural reasoning is used when the therapist thinks about the disability or disease and decides upon intervention to remediate identified problems. Narrative reasoning guides the therapist in evaluating the meaning that occupational performance limitations might have for the client. Pragmatic reasoning is used when addressing the practical realities associated with delivery of therapy services while looking at the context or contexts within which the client must perform his/her desired occupations. The therapist's personal situation such as clinical competencies, preferences for particular therapy techniques, commitment to the profession, and comfort level in working with certain clients/diagnoses is a part of the pragmatic reasoning process. Ethical reasoning is the process by which the therapist determines the most appropriate therapy intervention to address the client's occupational performance needs.¹⁹ The therapist's values and general worldview play an important role in ethical reasoning.¹¹ Keeping these points in mind and using professional reasoning skills when determining what and how to document will facilitate client care and reimbursement for therapy services.

Clinical Reasoning in Documentation

Clinical reasoning is the process used by occupational therapists to plan, direct, perform, and reflect on client care.¹⁹ Choosing appropriate **assessments** based on an understanding of the client's diagnosis and the areas of occupation that might be affected involves clinical reasoning. Skilled observations, theoretical knowledge, and clinical reasoning are used to identify, analyze, interpret, and document performance components that may contribute to the client's

Box 8-3

Examples of Clinical Reasoning

- Because of Mr. P's change in affect following his total hip replacement, the Geriatric Depression Scale will be administered and his primary physician will be contacted.
- Using neurodevelopmental techniques (NDT), including facilitation at the hips, the client is now able to independently stand at the sink with good balance for 2 minutes to brush his teeth.
- A home assessment is recommended to determine what adaptive equipment is necessary to allow the client to independently and safely complete ADL tasks.
- Mr. P's difficulty with problem solving, task initiation, and task progression impedes his ability to independently prepare a simple meal.
- A resting hand splint was fabricated for the client because of the emergence of spasticity, poor passive positioning of the upper extremity, and high risk for development of contractures.
- Mrs. R requires maximal assistance to complete upper/lower body dressing because of poor sitting balance, right neglect, and apraxia.

engagement in occupation. Occupational therapists demonstrate clinical reasoning when they include in their documentation information that demonstrates synthesis of information from the **occupational profile**, interpretation of assessment data to identify facilitators and barriers to client performance, collaboration with the client to establish goals, and a clear understanding of the demands, skills, and meaning of the activities used in intervention.⁴ Terminology used in documentation should reflect the unique **skilled services** that the occupational therapist uses to address client factors, performance skills, performance patterns, context and environment, and activity demands as they relate to the client's performance. **Box 8-3** provides some examples of clinical reasoning.

One of the greatest challenges for students and new therapists is writing notes that are concise yet comprehensive, including all of the relevant information necessary to meet the goals of documentation as described earlier.⁶ Most third party payers do not reimburse for time spent on documentation, so efficiency becomes essential. Although it is very important to accurately describe what occurred in the therapy session, care must be taken to keep this information to the point, relevant, and specific to established goals identified in the **intervention plan**. A common error is to describe each event that occurred in the intervention session in a step-by-step format. This is far too time-consuming and in fact does not meet the objectives of good documentation. Rather, short statements should be used that clearly and objectively convey necessary information to the reader. Abbreviations that are approved by and appropriate for the practice setting can be used to save time and space. Customized forms and checklists that include information relevant

to the practice setting help to streamline documentation and reduce time spent on narrative writing.

OT Practice Note

Concise, clear, accurate documentation that keeps the target audience in mind will ensure that appropriate information is conveyed to other health care professionals and will meet the criteria for reimbursement.

Legal Liability

The medical record is a legal document. All written and computerized therapy documentation must be able to endure a legal review. The medical record may be the most important document in a malpractice suit because it outlines the type and amount of care or services that were given.⁹ The therapist must know what information is necessary to include in the client record to reduce the risk of malpractice in a legal proceeding. All information must be accurate and based on first-hand knowledge of care. Deductions and assumptions are to be avoided; judgmental statements do not belong in the therapy notes. The therapist instead should describe the action, behavior, or signs and symptoms that are observed. As described earlier, it is considered fraudulent to alter the medical record in any way.

Initial Evaluation

The initial evaluation is a very important document in the occupational therapy process. It is the foundation upon which all other components of the client's program (including long- and **short-term goals**, the intervention plan, progress notes, and therapy recommendations) are based. Evaluation is the process of obtaining and interpreting data necessary for understanding the individual, system, or situation. It includes planning for and documenting the evaluation process, results, and recommendations, including the need for intervention.⁵ The Occupational Therapy Practice Framework-2⁴ stresses that the evaluation process should focus on identifying what the client wants and needs to do, as well as on identifying those factors that act as supports for or barriers to performance. The client's involvement in this process is essential in guiding the therapist in choosing appropriate tools to assess these areas. The occupational therapist takes into account the performance skills, performance patterns, context, activity demands, and client factors that are required for the client to successfully engage in occupation. This information must be articulated in the initial evaluation write-up.

A clear, accurately written accounting of the client's current status, as well as a description of his/her prior status,

is essential to justify the need for occupational therapy services. This initial report also provides necessary information to establish a baseline against which re-evaluation data and progress notes can be compared to demonstrate the efficacy of therapy intervention. The evaluation must clearly "paint a clinical picture" of the client's current functional status, strengths, impairments, and need for occupational therapy.

The evaluation should include an occupational profile of the client. The occupational profile includes information about the client's occupational history and experiences, patterns of daily living, interests, values, and needs.⁴ Information obtained from the occupational profile is essential in guiding the therapist to make clinically sound decisions about appropriate assessments, interventions, and goals.

Assessments are the tools, instruments, and interactions used during the evaluation process.⁵ These include standardized and nonstandardized tests. They can be written tests or performance checklists. Interviews and skilled observations are examples of assessments frequently used in the evaluation process. The specific assessments used are determined by the needs of the client and the practice setting in which the client is being seen. Assessments should be chosen that will evaluate the client's occupational needs, problems, and concerns. Clinical judgment skills are used to decide which assessments are appropriate and which areas should be evaluated. It is not necessary to evaluate every area of occupation and all performance skills for every individual. For example, it is not appropriate to assess a client's ability to cook a meal if he/she lives in a setting where meals are provided. Results of the assessment should be clearly identifiable and stated in measurable terminology that is standardized to the practice setting. [Table 8-1](#) shows an example of terminology that can be used to describe the level of assistance required during the performance of a functional task.

AOTA has outlined the recommended components of professional documentation used in occupational therapy in *Guidelines for Documentation of Occupational Therapy*.¹ Suggestions for what information should be included in evaluation and re-evaluation reports, intervention plans, **progress reports**, transition plans, and **discharge reports** are provided.

The evaluation report should contain the following information:

1. Client information: name/agency; date of birth; gender; applicable medical, educational, and developmental diagnosis; precautions; and contraindications
2. Referral information: date and source of referral; services requested; reason for referral; funding source; and anticipated length of service
3. Occupational profile: client's reason for seeking occupational therapy services; current areas of

■ **TABLE 8-1** | Levels of Assistance

Independent	Client is completely independent. No physical or verbal assistance is required to complete the task. Task is completed safely.
Modified independence	Client is completely independent with task, but may require additional time or adaptive equipment.
Supervised	Client requires supervision to safely complete task. A verbal cue may be required for safety.
Contact guard/standby assistance	Hands-on contact guard assistance is necessary for the client to safely complete the task, or the caregiver must be within arm's length for safety.
Minimum assistance	Client requires up to 25% physical or verbal assistance from one person to safely complete the task.
Moderate assistance	Client requires 26% to 50% physical or verbal assistance from one person to safely complete the task.
Maximal assistance	Client requires 51% to 75% physical or verbal assistance from one person to safely complete the task.
Dependent	Client requires more than 75% assistance to complete the task. Note: It is important to state whether assistance provided is physical or verbal assistance.

occupation that are successful and areas that are problematic; contexts that support or hinder occupations; medical, educational, and work history; occupational history; client's priorities; and targeted outcomes

4. Assessments: types of assessments used and results (e.g., interviews, record reviews, observations, standardized or nonstandardized assessments)
5. Analysis of occupational performance: description and judgment about performance skills; performance patterns; contextual or environmental aspects or features of activities; client factors that facilitate or inhibit performance; and confidence in test results
6. Summary and analysis: interpretation and summary of data as they relate to the occupational profile and referring concerns
7. Recommendation: judgment regarding appropriateness of occupational therapy services or other services

Intervention Plan

Upon completion of the assessment, the intervention plan is established. Information obtained from the occupational profile and the various assessments is analyzed, and a problem list is generated. Problem statements should include a description of the underlying factor (performance skill, performance pattern, client factor, contextual or environmental limitation, activity demand) and its impact on the related area of occupation.⁷ Based on the client's specific problems, the intervention plan is developed. The therapist must use theoretical knowledge and professional reasoning skills to develop long- and short-term goals, to decide upon intervention approaches, and to determine the interventions to be used to achieve stated goals. Recommendations and referrals to other professionals or agencies are also included in the plan.¹ The intervention plan is formulated on the basis of selected theories, frames of reference, practice models, and evidence.⁴ It is directed by the client's goals, values, beliefs, and occupational needs.

Establishment of the intervention plan is a collaborative effort between the therapist and the client or, if the client is unable, the client's family or caregivers. The plan is based on the client's goals and priorities.^{3,4} Although the primary responsibility for development of the intervention plan and goal setting is the role of the occupational therapist, the occupational therapy assistant may contribute to the process.⁵ Goals must be measurable and directly related to the client's ability to engage in desired occupations. The overarching goal of occupational therapy intervention is "engagement in occupation to support participation."⁴ This must be kept in mind at all times when developing long- and short-term goals. The Occupational Therapy Practice Framework-2 further identifies the outcome of occupational therapy intervention to be the method that assists the client to reach a state of physical, mental, and social well-being; to identify and attain aspirations; to satisfy needs; and to change or cope with the environment.⁴ Documentation that uses this terminology will support the unique focus that occupational therapy contributes to the client care plan and the rehabilitation process.

The client intervention plan contains both short- and **long-term goals**. Some therapists prefer to use the term *objective* in place of *short-term goal*. Short-term goals or objectives are written for specific time periods (e.g., 1 or 2 weeks) within the overall course of the client's therapy program. They are periodically updated as the client progresses or in accordance with the guidelines of the practice setting or payer requirements. Short-term goals are the steps that lead to accomplishment of the long-term goal, which is also called the *discharge goal* in some settings. The long-term goal is generally considered to be the overall functional goal of the intervention plan and is broader in nature than the short-term goal. For example, the client's long-term goal may be to become independent with dressing. One short-term goal to accomplish this might be that the client will

be able to independently don and doff a simple pull-over shirt without fasteners. When this short-term goal is achieved, a subsequent goal might be for the client to be able to dress independently in a shirt with buttons. Eventually, lower extremity dressing would be added as an objective, then socks, shoes, and outerwear, until the long-term goal of independent dressing is achieved.

Establishing functional, client-centered goals that focus on engagement in occupations and activities to support participation in life is central to the philosophy of occupational therapy.⁴ Skillful goal writing requires practice and careful consideration of the desired outcome of therapy intervention. Client-centered goals are written to reflect what the client will accomplish or do, **not** what the therapist will do, and are written in collaboration with the client. An important characteristic of a goal is that it must reflect an outcome, not the process used to achieve the outcome.¹⁶ “*The client will be taught energy conservation techniques to use during dressing*” is an example of a poorly written goal that focuses on the process, rather than the outcome of therapy. The correct way to write the goal would be “*The client will independently use three energy conservation techniques during dressing.*” Goals must be *objective* and *measurable* and must include a *time frame*, which may be discussed in a separate section of the evaluation form. The expected behavior is clearly stated, using concrete terms that describe a specific functional task, action, behavior, or activity (the client will don pants); also, a measurable expectation of performance is identified (independently), with conditions or circumstances that support the outcome listed (using a dressing stick). Well-written goals contain all of the components listed here and avoid the use of vague or ambiguous terms that may be misunderstood by the reader (Table 8-2).

Once goals are established, the therapist, in collaboration with the client, chooses appropriate interventions that will lead to goal attainment. The plan consists of **skilled interventions** that the therapist will provide throughout the client’s therapy program. Interventions are chosen that involve the therapeutic use of self; the therapeutic use of occupations or activities (occupation-based activity, purposeful activity, preparatory methods); and consultation and client/caregiver education and advocacy.⁴ Examples of occupational therapy interventions include activities of daily living (ADL) training; instrumental activities of daily living (IADL) training; therapeutic activities; therapeutic exercises; splint/orthotic fabrication, modification, and application; neuromuscular retraining; cognitive-perceptual training; and discharge planning. The OTPF-2 outlines various approaches that may guide the intervention process (Table 8-3). These approaches are based on theory and evidence. It is expected that the intervention plan will be modified according to client needs and priorities and responses to the interventions. Modifications to the intervention plan must be documented in the client record in the weekly or monthly progress report.

■ **TABLE 8-2** | Examples of Short- and Long-Term Goals

Short-Term Goal (to be completed in 2 weeks)	Long-Term Goal (to be completed in 4 weeks)
Client will prepare a cup of tea with minimal verbal assistance for safety and technique.	Client will independently adhere to safety precautions during simple cooking tasks 100% of the time.
Client will brush teeth with moderate physical and verbal assistance while seated at the sink.	Client will complete morning hygiene and grooming independently after task set-up while seated at the sink.
Client will don socks with minimal assistance using a sock aid while seated in a wheelchair.	Client will independently complete lower body dressing without assistive devices while seated at the edge of the bed.

Progress Reports

Progress toward goal attainment is an expected criterion for reimbursement of occupational therapy services. Documentation that demonstrates progression toward goal achievement is critical to support the need for ongoing therapy. The purposes of the progress report are to document the client’s improvement, to describe the skilled interventions provided, and to update goals. Progress reports can be written daily or weekly depending on the requirements of the work site and the payer source. Various reporting formats are used to document client progress. The most prevalent formats used in physical disabilities settings include **SOAP notes**, **checklist notes**, and **narrative notes**.

Regardless of the format used, progress reports should identify the following key elements of the intervention session: the client outcome (using measurable terminology from the OTPF-2); the skilled interventions provided by the occupational therapist; and progress that resulted from the occupational therapy intervention. Skilled interventions are those that require the expertise, knowledge, clinical judgment, decision making, and abilities of an occupational therapist.¹⁴ Skilled therapy services have a level of inherent complexity such that they can only be performed safely and/or effectively by or under the general supervision of a qualified therapist. Skilled services include evaluation; determination of effective goals and services in collaboration with the client and the client’s caregivers and other medical professionals; analysis and modification of functional activities and tasks; determination that the modified task obtains optimum performance through tests and measurements; client/caregiver training; and periodic re-evaluation of the client’s status with corresponding readjustment of the

TABLE 8-3 | Occupational Therapy Intervention Approaches

Create, promote (health promotion)	<ul style="list-style-type: none"> An intervention approach designed to provide enriched contextual and activity experiences to enhance performance for persons in the natural contexts of life. Focus is on performance skills, performance patterns, context or contexts or physical environments, activity demands, and client factors (body functions, body structures).
Establish, restore (remediation, restoration)	<ul style="list-style-type: none"> An intervention approach designed to change client variables to develop a skill or ability that has not yet been developed or to restore a skill or ability that has been impaired. Focus is on performance skills, performance patterns, and client factors (body functions, body structures).
Maintain	<ul style="list-style-type: none"> An intervention approach designed to provide the supports that will allow the client to maintain his/her performance capabilities. Without continued maintenance intervention, client performance would decline and/or occupational needs would not be met, thereby affecting health and quality of life. Focus is on performance skills, performance patterns, context or contexts or physical environments, activity demands, and client factors.
Modify (compensation, adaptation)	<ul style="list-style-type: none"> An intervention approach designed to find ways to revise the current context or activity demands to support performance. This includes using compensatory techniques, enhancing some features to provide cues, or reducing features to reduce distractibility. Focus is on performance patterns, context or contexts or physical environments, and activity demands.
Prevent (disability prevention)	<ul style="list-style-type: none"> An intervention approach designed to prevent the occurrence or development of barriers to performance in context. This approach is directed toward clients with or without a disability who are at risk for occupational performance problems. Focus is on performance skills, performance patterns, context or contexts or physical environments, activity demands, and client factors.

occupational therapy program. The therapist’s skills may be required for safety reasons, or they may be required to establish and teach the client a compensatory strategy to improve independence and safety. **Box 8-4** shows examples of terminology that can be used to demonstrate provision of skilled services.

Documentation of skilled services includes a description of the type and complexity of the skilled intervention and must reflect the therapeutic rationale underlying the task. Reimbursement for clinical services provided is dependent on documentation that demonstrates the clinical reasoning that underlies the intervention. The progress note must reflect progress made toward established goals. Comparison statements are an excellent way to convey this information. Current status information is compared with baseline evaluation findings to clearly identify progress: *Client now requires minimal assistance to regain sitting posture during lower body dressing (last week required moderate assistance)*. Documentation that includes functional assessment scores from validated tests and measurements to demonstrate client progress provides strong justification for reimbursement of therapy services. A statement explaining why additional therapy services are needed substantiates the need for ongoing therapy: *Occupational therapy services are required for facilitation of balance and postural corrections during lower body dressing training*. Goals are modified and updated on the basis of client progress: *Client will don pants independently, without loss of balance, while seated at the edge of the bed*. Upgrading of the client’s goals can consist of reducing the amount of assistance required to complete the task, increasing the complexity of the task, or introducing a new component to the activity. This is an ongoing process, and

meticulous documentation is necessary to demonstrate the need for continued occupational therapy services.

SOAP Notes

The SOAP note format was first introduced by Dr. Lawrence Weed in 1970 as a method of charting in the **problem-oriented medical record (POMR)**.²⁰ In the POMR, which focuses on a client's problems instead of on his/her diagnosis, a numbered problem list is developed that becomes an important part of the medical record. Each member of the health care team writes a SOAP note to address problems in the list that are specific to his/her area of expertise. The POMR is constantly modified and updated throughout the client's stay. The SOAP note is one of the most frequently used formats for documenting patient status. Each letter in the acronym SOAP stands for the name of a section of the note:

- S = Subjective
- O = Objective
- A = Assessment
- P = Plan

The *subjective* (S) part of the note is the section where the therapist includes information reported by the client. Information provided by the family or caregivers can also be included here. Many different types of statements can be included in the subjective section of the SOAP note. Any information that the client gives the therapist about his/her current condition, functional performance, limitations, general health status, social habits, medical history, or goals is appropriate to include in this section.¹² A client's subjective response to treatment is recorded in this section. Direct quotes can be used when appropriate. Family, caregivers and others involved in the client's care can also provide valuable information. For example, nursing may report that the client was unable to feed himself or herself at breakfast, or a family member may supply information on the client's normal routine before hospitalization. If the client is non-verbal, gestures, facial expressions, and other types of non-verbal responses are appropriate to include. This information can be used to demonstrate improvement, support the benefit of chosen interventions, document the client's response, and show client compliance. However, discretion must be used when deciding what information to include. Using careful, effective communication skills during client treatment sessions will enhance the therapist's ability to gather relevant subjective information about the client's attitudes and concerns that can be used to ensure proper intervention and appropriate documentation.⁷

The *Subjective* section should include only relevant information that will support the therapist's decision regarding which assessments should be used and which goals are appropriate for this client. The therapist should avoid statements that can be misinterpreted or that can jeopardize reimbursement. Subjective statements that do not relate to information in the other parts of the note are not useful.

Negative quotes from the client that do not relate to the intervention session are not necessary or beneficial to include. If there is nothing relevant to report in the *Subjective* section, it is permissible to not include a statement. In this case, write a circle with a line through it (0) to indicate that you have intentionally left the section blank.¹⁸

In the *Objective* (O) section of the SOAP note, the therapist documents the results of assessments, tests, and measurements performed, as well as objective observations.¹² Data that are recorded in the *Objective* section are measurable, quantifiable, or observable. Only factual information may be included. Results of standardized and non-standardized tests are documented in this part of the note. Measurable performance of functional tasks (basic activities of daily living [BADL], IADL), range-of-motion (ROM) measurements, muscle grades, results of sensory evaluations, and tone assessments are examples of appropriate information for this section of the SOAP note. It is important that the therapist not interpret or analyze data in the *Objective* section. Rather, statements should include only concise, specific, objective recordings of the client's performance. Simply listing the activities that the client engaged in is not sufficient. The emphasis is on the **results** of the interventions, not on the interventions themselves. Information in the *Objective* section can be organized chronologically, discussing the results of each treatment event in the order it occurred during the session, or categorically.⁷ Information that is organized categorically should follow the categories outlined in the Occupational Therapy Practice Framework-2: performance skills, performance patterns, context, activity demands, and client factors.⁴ Table 8-4 shows examples of documentation that can be used in the *objective* section.

In the *Assessment* (A) section of the SOAP note, the therapist draws from the subjective and objective findings and interprets the data to establish the most appropriate therapy program. In this section, impairments and functional deficits are analyzed and prioritized to determine what impact they have on the client's occupational performance and ability to engage in meaningful occupation. Only information that was included in the *Subjective* or *Objective* section is discussed in the *Assessment* section. Clinical reasoning is required to analyze the information and develop the intervention plan. The *Assessment* portion of the SOAP note is where the therapist demonstrates his or her ability to summarize relevant assessment findings, synthesize the information, analyze its impact on occupational performance, and utilize it to formulate the intervention plan. It requires keen observation, clinical reasoning, and judgment skills, as well as an ability to identify relevant factors that inhibit or facilitate performance. The *Assessment* section should end with a statement justifying the need for continued therapy services: *Client would benefit from activities that encourage trunk rotation and forward lean to facilitate transfers and lower body dressing.*⁷ Insight and skill in completing the *Assessment* section improve with clinical experience.

■ **TABLE 8-4** | Examples of Categories and Documentation for Objective Section of SOAP Note

Category	Objective Documentation
ADL task performance	Note how each of the performance skills and client factors affects completion of ADL tasks. Include assist levels and set-up needed, adaptive equipment required, or techniques used. Include client response to treatment.
Posture and balance	Note whether balance was static or dynamic. Note whether the client leans in one direction, has rotated posture, or has even or uneven weight distribution. Note the position of the head and what cues or feedback was necessary to maintain or restore balance.
Coordination	Include hand dominance, type of prehension used, ability to grasp and maintain grasp, reach and purposeful release, object manipulation, and gross versus fine motor ability
Swelling or edema	Give volumetric measurements if possible, pitting or nonpitting type.
Movement patterns in affected upper extremities	Note tone, tremors, synergy pattern, facilitation required, and stabilization.
Ability to follow directions	Note type and amount of instruction required and ability to follow one-, two-, or three-step directions.
Cognitive status	Report on initiation of task, verbal responses, approach to the task, ability to stay on task, sequencing, orientation, and judgment.
Neurologic factors	Note perseveration, sensory losses (specific), motor deficits, praxis, spasticity, flaccidity, rigidity, neglect, bilateral integration, and tremors.
Functional mobility	Note type of assistance required for the client to complete all types of mobility.
Psychosocial factors	Note client's overall mood, affect, and ability to engage with others. Also note family support, response to changes in body image, and ability to make realistic discharge decisions.

From Borcharding S: *Documentation manual for writing SOAP notes in occupational therapy*, ed 2, Thorofare, NJ, 2005, Slack.

The intervention plan is outlined in the *Plan (P)* section. As the client achieves the short-term goals, the plan is revised and new short-term goals are established. Documentation reflects the client's updated goals, as well as any modifications to the frequency of therapy. Suggestions for additional interventions are also included in this section. This information will guide subsequent treatment sessions. Figure 8-1 is an example of a progress note using the SOAP format.

Narrative Notes

The narrative note is another format used to document daily client performance. One way to organize the narrative note is to categorize the information into the following subsections: problem, program, results/progress, and plan. The *problem* being addressed in the treatment intervention should be clearly identified. The impairment, as well as the functional impact, is stated. The intervention or intervention modality is identified in the *program* section. The *results*, including progress, are documented in measurable, objective terminology. Barriers to progress are included in this section. The plan for future intervention is outlined in the *plan* section. The need to modify goals and the rationale for this would be included here. In some practice settings, the narrative note is written directly in the medical chart.

S: Client states that “it takes too much energy to dress each day and my hands are too stiff to manage buttons and ties anyways.” Client's family reports that client no longer seems interested in self-care activities.

O: Client became SOB with seated self-care task (dressing) after 5 minutes of activity. Client required minimal assistance for upper body dressing, moderate assistance to don pants and maximal assistance to don shoes (last week she required maximal assistance with all tasks). Client had moderate difficulty with buttons (last week she was unable to button blouse). Client was unable to tie shoes. BUE shoulder strength is 3+/5 (was 3/5).

A: Client is improving in her ability to complete her self-care tasks. COPD still interferes with ADL independence. She may benefit from adaptive equipment for lower body dressing.

P: Continue ADL training: assess for independence with adaptive equipment (dressing stick, long-handled shoe horn, and elastic shoe laces). Instruct client in energy-conservation techniques during ADL task completion. Instruct client in AROM exercises before beginning morning ADL tasks.

FIGURE 8-1 SOAP (Subjective, Objective, Assessment, Plan) note.

Problem:	Client was seen for 60 minutes. IADL task: light meal preparation
Results:	Client was able to assemble necessary items to prepare a simple sandwich with minimal verbal cues, which were necessary because of unfamiliarity with clinic kitchen. Minimal verbal assistance was necessary for task initiation and progression from one step to the next. Although physical assistance was not required, client demonstrated mild coordination deficits resulting in difficulty opening jars, manipulating knife, and opening packages. Endurance was good for this activity — client was able to stand for 30 minutes without rest.
Plan:	Therapeutic exercise and activities will be performed to improve coordination. Instruct client in strategies for improving task initiation. Progressive IADL assessment — hot meal preparation

FIGURE 8-2 Narrative progress report.

Occupational therapy may have a designated area in the medical chart to write notes, or all clinicians involved with the client may document on a single comprehensive interdisciplinary note. The date and often the beginning and ending times of the therapy session must be included in the note. The therapist's signature follows the last word of the note. Figure 8-2 is an example of a narrative note using this format.

A narrative format may also be used to write any type of information that the therapist wishes to convey to the other team members. For example, the therapist may document that the evaluation was initiated, or that the client was unable to attend therapy because of illness. Documentation of communication between team members regarding the client's program may be expressed in a narrative format.

Descriptive Notes

At times, a short descriptive note is useful to relay important information about the client. Although it is preferable to keep notes as objective as possible, it is sometimes appropriate to include subjective information. Judgmental comments, negative statements, comments about other staff members, and information not directly related to the client's intervention program do not belong in the official medical record. Unobserved behaviors that are included in the client record should be recorded as such and a clear explanation provided as to who provided the information to the therapist.

Progress Checklists or Flow Sheets

Checklists or flow sheets can be used to document daily performance in a concise, efficient manner. High productivity demands in many settings, as well as lack of reimbursement for documentation, have made this type of documentation a useful option. Flow sheets typically use a

table or graph format to record measurements at regular intervals, usually after each session. Advantages of using a flow sheet or a checklist to document daily performance on specific tasks include improved clarity and organization of data; reduction in the quantity of data that need to be recorded after each session; improved focus on interventions that are specific to the client's goals; and ease in clearly identifying the client's functional status and progress.¹⁸ A disadvantage of using this format for documentation is that often space is not sufficient for the therapist to include subjective statements to explain client performance, document the therapist's interpretation of the objective information, or describe the client's response to the intervention. The checklist provides a description of what the client did based on a level of assistance or an objective measurement, but it does not provide information on the quality of how the task was accomplished or modifications that were made to facilitate successful completion of the task. However, this information can be included in a narrative format on a separate note sheet. Information from the daily checklist or flow sheet is used to write a weekly progress note.

RUMBA

According to Perinchieff,¹⁷ a tool such as the RUMBA (also called RHUMBA) test can be beneficial in organizing the therapist's thought processes for effective documentation. RUMBA and RHUMBA are acronyms; each letter identifies something that the therapist should keep in mind when writing goals and documenting the therapeutic process:⁸

- Is the information **R**elevant (the outcome must be relevant)? *The goal/outcome must relate to something.*
- **H**ow long will it take? *Indicate when the goal/outcome will be met.*
- Is the information **U**nderstandable? *Anyone reading it must know what it means.*
- Is the information **M**easurable? *There must be a way to know when the goal has been met.*
- Is the information **B**ehavioral (describes behaviors)? *The goal/outcome must be something that is seen or heard.*
- Is the outcome **A**chievable (realistic)? *The goal/outcome must be do-able and realistic.*

The therapist can review the documentation to determine whether these questions have been answered, all the while keeping the target audience in mind.

SMART

Another system that may assist the therapist in writing goals is SMART goals. SMART acronyms stand for significant (and simple), measurable, achievable, related, and time-limited.¹⁸

- Achieving this goal will make a **S**ignificant difference in the client's life.
- You have a clear, **M**easurable target to aim for, and you will know when the client has reached the goal.

- It is reasonable that the client could **Achieve** this goal in the time allotted.
- Long- and short-term goals **Relate** to each other, and the goal has a clear connection to the client’s occupational needs.
- The goal is **Time-limited**: Short- and long-term goals have a designated chronological end point.⁸

Discharge Reports

Discharge reports are written at the conclusion of the therapy program. A comparison statement of functional performance from initial evaluation to discharge is documented to demonstrate progress. Emphasis should be placed on the progress the client has made in engaging in occupations. A summary of the skilled interventions provided to the client is also included. Discharge recommendations (e.g., home programs, therapy follow-up, referral to other programs) are made to facilitate a smooth transition from therapy. Clients are discharged from therapy when they have achieved established goals, have received maximal benefit from occupational therapy services, have refused to participate in further therapy, or have exceeded reimbursement allowances. The discharge summary should clearly demonstrate the efficacy of occupational therapy services and is often used to obtain information for outcome studies.

Types of Documentation Reporting Formats

Documentation can be paper based (written record) or computer generated. The written medical record is still the most widely used method for recording information; however, the electronic medical record (EMR) is becoming more common, especially in large hospital settings. Computerized documentation can be used to record all aspects of the occupational therapy process from the evaluation report to the discharge report. Reporting forms can be inputted into the computer, and results of initial evaluation and the discharge report can be typed directly onto the forms. This guarantees legibility and ensures that no areas are left uncompleted. Increased numbers of regulations, more complex reimbursement structures, and pressure to achieve increased productivity are placing pressure on our current systems; therefore, use of an electronic documentation program may improve therapists’ efficiency.¹⁰

Computerized evaluation forms and progress notes are formatted to meet the needs of the facility and include information required for reimbursement (Figure 8-3). Therapists often are able to choose responses from a pull-down menu, thereby reducing time spent in deciding upon the appropriate terminology to use (Table 8-5). Space is usually available to include narrative information as well. Because all health care providers enter information on a common database, members of the team are able to quickly access information about the patient by reviewing relevant sections

■ **TABLE 8-5** | **Definitions of Level of Assistance Based on the Functional Independence Measure (FIM)**

The FIM measures level of assistance in various domains on a seven-point scale.

FIM Levels

No Helper

7	Complete independence (timely, safety)
6	Modified independence (device)

Helper—Modified Dependence

5	Supervision (subject = 100%)
4	Minimal assistance (subject = 75% or more)
3	Moderate assistance (subject = 50% or more)

Helper—Complete Dependence

2	Maximal assistance (subject = 25% or more)
1	Total assistance or not testable (subject less than 25%)

on the computerized medical chart. One of the problems or inconveniences that may occur with computerized documentation involves the accessibility of computers. Therapists must allow time to locate a computer that is not in use, so that they can enter their data. Because notes must be entered in chronological order, this sometimes becomes an issue if a computer is not available, as the therapist may not be able to wait until the next day to enter information. Some forms that are on the computer are very restrictive in terms of what information the therapist may enter. This may make it difficult for the therapist to adequately document the session. Often a long time lapse occurs between updates of computer programs. In general, however, computerized documentation and billing can be an asset in the therapy setting. It can enhance therapist productivity by reducing the amount of time spent writing and can guide the new therapist in choosing appropriate responses and terminology to document what occurred with the client.

Many different written formats can be used to document occupational therapy services. The content of the form used is usually determined by the requirements of the third party payer reimbursing the service and the unique needs of the practice setting. As stated before, documentation must contain the information necessary to justify the need for occupational therapy services, must demonstrate the provision of skilled therapeutic interventions, and must show client progress toward identified goals. Occupational therapy documentation should address all of these components to ensure reimbursement and to convey accurate information about client performance.

FIGURE 8-3 Computerized documentation form.

The primary reimbursement systems for occupational therapy services in the physical disabilities setting include Medicare, Medicaid, and various Health Maintenance Organizations (HMOs) and Preferred Provider Organizations (PPOs). Each of these organizations requires specific

information that must be included in the documentation for reimbursement to occur. Individual facilities (e.g., hospitals, clinics, home health agencies, skilled nursing facilities) design documentation forms to meet their specific needs and to ensure that the information necessary for

reimbursement is included. Billing systems may also influence the type of documentation format that is used in a particular setting.

Medicare is a major payer source in the geriatric physical disability setting. Medicare is a national insurance program and as such has set national standards for documentation. This government agency has put forth detailed guidelines stating expectations for what information must be included in the medical record to justify the need for occupational therapy services. Intermediaries will reimburse occupational therapy services only if all of the requirements established by the **Medicare guidelines** and regulations have been met. The Medicare Benefit Policy Manual (www.cms.gov/manuals/Downloads/bp102c15pdf) describes the key words and phrases medical reviewers are looking for when they review a claim for payment. Medicare requires that specific information is clearly documented for each part of the therapy process for therapy services to be reimbursed. Many other payers of therapy services in adult rehabilitation follow Medicare guidelines when establishing documentation policies for reimbursement.¹⁸ An understanding of these requirements is critical in ensuring reimbursement for services provided. The therapist working with Medicare clients must become familiar with these guidelines and regulations to prevent denial of services. Detailed information can be found at the Medicare Website.

Although its exclusive use is no longer required, Medicare has designed a specific form for outpatient evaluations called the Medicare 700 form, the “Plan of Treatment for Outpatient Rehabilitation.” This form specifies the information required by Medicare. Figure 8-4 shows this form and directions for completing it. Documentation on the initial evaluation must demonstrate that it is reasonable and necessary for the therapist to complete the evaluation to

determine whether restorative or maintenance services are appropriate. It is important to fill in all spaces on the 700 form. Failure to complete a section of the form could result in a technical denial. It is important to include a statement of the client’s prior level of function and the change in function that precipitated the occupational therapy referral. Results from assessments that support the need for therapy intervention are recorded in this section. Objective tests and measurements are used to establish baseline data. This information will serve as the basis for short- and long-term goals.

Many rehabilitation companies and hospitals have modified the 700 form with headings and checklists to assist the therapist in providing the type of information that will support the need for therapy services (Figure 8-5). Space on the 700 form is limited, and the therapist must be able to concisely present data that will clearly demonstrate the need for occupational therapy. A recent change in function (a decline or an improvement) is required to justify therapy. The plan of treatment (Section 12) includes functional, measurable goals based on assessment results as described in Section 18. Goals cannot address issues that do not have supporting baseline data in the Assessment section. The plan of treatment is the skilled intervention that the therapist will provide. The 700 form also functions as the end-of-month progress report and/or as the discharge form. Section 20 is completed at the end of the billing period. Progress, current functional status, and skilled interventions provided during the previous month are included here.

Figure 8-6 is an example of an initial evaluation form used in a rehabilitation center. It has been modified to meet the specific needs of the practice setting. Figure 8-7 shows an example of an occupational therapy evaluation report

INSTRUCTIONS FOR COMPLETION OF FORM CMS-700

(Enter dates as 6 digits, month, day, year).

<ol style="list-style-type: none"> 1. Patient's Name - Enter the patient's last name, first name and middle initial as shown on the health insurance Medicare card. 2. Provider Number - Enter the number issued by Medicare to the billing provider (<i>i.e.</i>, 00-7000). 3. HICN - Enter the patient's health insurance number as shown on the health insurance Medicare card, certification award, utilization notice, temporary eligibility notice, or as reported by SSO. 4. Provider Name - Enter the name of the Medicare billing provider. 5. Medical Record No. - (<i>optional</i>) Enter the patient's medical/clinical record number used by the billing provider. 6. Onset Date - Enter the date of onset for the patient's primary medical diagnosis, if it is a new diagnosis, or the date of the most recent exacerbation of a previous diagnosis. If the exact date is not known enter 01 for the day (<i>i.e.</i>, 120191). The date matches occurrence code 11 on the UB-92. 7. SOC (start of care) Date - Enter the date services began at the billing provider (the date of the first Medicare billable visit which remains the same on subsequent claims until discharge or denial corresponds to occurrence code 35 for PT, 44 for OT, 45 for SLP and 46 for CR on the UB-92). 8. Type - Check the type therapy billed; <i>i.e.</i>, physical therapy (PT), occupational therapy (OT), speech-language pathology (SLP), cardiac rehabilitation (CR), respiratory therapy (RT), psychological services (PS), skilled nursing services (SN), or social services (SW). 9. Primary Diagnosis - Enter the pertinent written medical diagnosis resulting in the therapy disorder and relating to 50% or more of effort in the plan of treatment. 10. Treatment Diagnosis - Enter the written treatment diagnosis for which services are rendered. For example, for PT the primary medical diagnosis might be Degeneration of Cervical Intervertebral Disc while the PT treatment DX might be Frozen R Shoulder or, for SLP, while CVA might be the primary medical DX, the treatment DX might be Aphasia. If the same as the primary DX enter SAME. 11. Visits From Start of Care - Enter the cumulative total visits (<i>sessions</i>) completed since services were started at the billing provider for the diagnosis treated, through the last visit on this bill. (<i>Corresponds to UB-92 value code 50 for PT, 51 for OT, 52 for SLP, or 53 for cardiac rehab.</i>) 12. Plan of Treatment/Functional Goals - Enter brief current plan of treatment goals for the patient for this billing period. Enter the major short-term goals to reach overall long-term outcome. Enter the major plan of treatment to reach stated 	<p>goals and outcome. Estimate time-frames to reach goals, when possible.</p> <ol style="list-style-type: none"> 13. Signature - Enter the signature (<i>or name</i>) and the professional designation of the professional establishing the plan of treatment. 14. Frequency/Duration - Enter the current frequency and duration of your treatment; <i>e.g.</i>, 3 times per week for 4 weeks is entered 3/Wk x 4Wk. 15. Physician's Signature - If the form CMS-700 is used for certification, the physician enters his/her signature. If certification is required and the form is not being used for certification, check the ON FILE box in item 18. If the certification is not required for the type service rendered, check the N/A box. 16. Date - Enter the date of the physician's signature only if the form is used for certification. 17. Certification - Enter the inclusive dates of the certification, even if the ON FILE box is checked in item 18. Check the N/A box if certification is not required. 18. ON FILE (Means certification signature and date) - Enter the typed/printed name of the physician who certified the plan of treatment that is on file at the billing provider. If certification is not required for the type of service checked in item 8, type/print the name of the physician who referred or ordered the service, but do not check the ON FILE box. 19. Prior Hospitalization - Enter the inclusive dates of recent hospitalization (<i>1st to DC day</i>) pertinent to the patient's current plan of treatment. Enter N/A if the hospital stay does not relate to the rehabilitation being rendered. 20. Initial Assessment - Enter only current relevant history from records or patient interview. Enter the major functional limitations stated, if possible, in objective measurable terms. Include only relevant surgical procedures, prior hospitalization and/or therapy for the same condition. Include only pertinent baseline tests and measurements from which to judge future progress or lack of progress. 21. Functional Level (end of billing period) - Enter the pertinent progress made and functional levels obtained at the end of the billing period compared to levels shown on initial assessment. Use objective terminology. Date progress when function can be consistently performed. When only a few visits have been made, enter a note indicating the training/treatment rendered and the patient's response if there is no change in function. 22. Service Dates - Enter the From and Through dates which represent this billing period (<i>should be monthly</i>). Match the From and Through dates in field 6 on the UB-92. DO NOT use 00 in the date. Example: 01 08 91 for January 8, 1991.

Confidentiality and Documentation

Maintaining **confidentiality** in documentation is the responsibility of the occupational therapist. Principle 3E of the AOTA Code of Ethics addresses the issue of **privacy** and confidentiality in all forms of communication, including documentation. “Occupational therapy personnel shall protect all privileged confidential forms of written, verbal, and electronic communication gained from educational, practice, research, and investigational activities unless otherwise mandated by local, state, or federal regulations.”³ *Guidelines to the Code of Ethics*² speaks directly to confidentiality issues:

Information that is confidential must remain confidential. This information cannot be shared verbally, electronically, or in writing without appropriate consent. Information must be shared on a need-to-know basis only with those having primary responsibilities for decision making.

5.1 All occupational therapy personnel shall respect the confidential nature of information gained in any occupational therapy interaction.

5.2 Occupational therapy personnel shall respect the individual’s right to privacy.

5.3 Occupational therapy personnel shall take all due precautions to maintain the confidentiality of all verbal, written, and electronic, augmentative, and nonverbal communications (as required by HIPAA)² (p. 655). **Ethical practice** demands that the therapist understand what is meant by confidential information and is knowledgeable about how to maintain client confidentiality. Information about clients, including their names, diagnoses, and intervention programs, cannot be discussed outside of the treatment environment. Client charts should not be removed from the facility. Reports containing personal information (name, social security number, medical diagnosis, etc.) cannot be left out in plain view, where others can read the information. Therapists, students, and staff cannot discuss clients in public areas where others may overhear the conversation.

Federal laws have been enacted to protect the consumer against breaches of confidentiality. The privacy sections of HIPAA clearly outline the expectations of health care professionals in issues of confidentiality. HIPAA was initially enacted in 1996 and consisted of a series of provisions that required the Department of Health and Human Services to adhere to national standards for electronic transmission of health care information. The law also required that health care providers adopt privacy and security standards by which to protect confidential medical information of patients. Beginning in April 2003, health care providers were required to adhere to the privacy standards mandated

by HIPAA. Individually identifiable health information, also known as protected health information (PHI), is federally protected under HIPAA regulations. PHI is health information that relates to a past, present, or future physical or mental health condition. This rule limits the use and disclosure of PHI to the minimum necessary to carry out the intended purpose. It also gives patients the right to access their medical records. This regulation protects the medical records of clients, whether the information is written or electronic (computer) or is verbally communicated. Violations of the HIPAA rulings are subject to criminal or civil sanctions.⁹

The law requires that all staff be trained in HIPAA policies and procedures and understand the implications specific to the work setting. In addition to the client confidentiality procedures explained earlier, safeguards must now be adhered to for compliance with HIPAA regulations. The therapist has a responsibility to protect confidential information from unauthorized access, use, or disclosure. This includes information documented in the medical record. Papers, reports, and forms containing PHI should not be disposed of in the regular trash. Instead they must be shredded. Never leave medical records or portions of records (i.e., therapy notes) unattended in public view. Information (written, verbal, or electronic) cannot be shared with family members unless permission has been provided in writing by the client.

If documentation is done electronically, special care must be taken to prevent unauthorized persons from accessing client information. Log-in pass codes cannot be shared among staff. Therapists must take care to ensure privacy when entering information.

Ethical Considerations

Special safety measures such as personal identification and user verification codes for access to records should be established to prevent unauthorized persons from accessing client records.^{9,15}

Summary

Documentation is a necessary part of the occupational therapy process. The occupational therapist has a responsibility to the client, to the employer, and to the profession to develop the skills that will allow him/her to accurately document the therapy process. Well-written documentation promotes the profession by providing proof of the value of occupational therapy intervention. It can provide valuable information for outcome research and evidence-based practice. It is a professional expectation that the occupational therapist will keep current on documentation requirements for his/her practice area and will acquire the skills necessary to accurately document the occupational therapy process.

Threaded Case Study | Jane, Part 2

Reflect upon the questions posed earlier regarding the case presented at the beginning of this chapter. Jane, the new occupational therapist beginning her first job at the Skilled Nursing Facility, must use clinical reasoning skills at all stages of the therapy process, including the documentation of services delivered. The evaluation, the intervention plan, and short-term and long-term goals are written in keeping with sound clinical reasoning. Evidence of this must be reflected in the documentation provided by Jane. It is essential that

occupational therapy notes also indicate the skilled service or skilled intervention that was provided for reimbursement purposes. The format used for recording this information, as well as the terminology utilized, may be specific to the practice setting. Federal privacy mandates (HIPAA) and the Occupational Therapy Code of Ethics must be adhered to at all times during all methods of documentation, whether written, verbal, or computer generated.

■ Learning Objectives *After studying this chapter, the student or practitioner will be able to do the following:*

1. Recognize the role of occupational therapy personnel in preventing accidents.
2. Identify recommendations for safety in the clinic.
3. Describe the purposes of special medical equipment.
4. Identify precautions that should be taken when treating clients who require special equipment.
5. Identify Standard Precautions for infection control and explain the importance of following them with all clients.
6. Describe proper techniques of hand-washing.
7. Recognize the importance for all health care workers to understand and follow standard procedures used in client care to prevent the transmission of infectious agents.
8. Identify proper procedures for handling client injuries.
9. Describe guidelines for handling various emergency situations.

Threaded Case Study Donna, Part 1

Donna is a registered occupational therapist hired as Director of Occupational Therapy (OT) Services in a recently opened community hospital. This 300-bed general acute care hospital provides inpatient and outpatient services for individuals with a wide range of medical needs, including cardiac problems, brain injury, neurologic and orthopedic problems, and needs in oncology, obstetrics, and gynecology. Occupational therapy services are provided in acute care, skilled nursing, acute rehabilitation, and outpatient units.

As Director of OT Services, Donna must establish policies and procedures pertaining to client safety, infection control, medical emergencies, and precautions with special equipment. Donna must develop written guidelines and must identify and/or develop training requirements to ensure adequate orientation and preparation of OT personnel.

Critical Thinking Questions

In preparing these policies and procedures, Donna must consider the following:

1. What general safety procedures and infection control standards should be followed to maintain a safe clinic environment?
2. What items of specialized medical equipment are occupational therapy personnel likely to encounter in their intervention with clients, and what precautions should be taken when treating a client who requires special equipment?
3. What are the basic guidelines and/or procedures to be applied in emergency situations?
4. What resources are available to health care providers that offer the most current information pertaining to safety procedures and infection control?

As you read through the chapter, keep in mind these questions and any other concerns confronting Donna in developing protocols, policies, and procedures for the safety of clients and OT personnel.

Ethical Considerations

Occupational therapists have an ethical obligation to “demonstrate a concern for the well-being and safety of the recipients of their services” (S21).¹ To meet these ethical obligations to clients, and to provide a physical context that supports clients’ engagement in meaningful occupations, occupational therapists need to be educated in proper safety procedures, infection control standards, and emergency interventions.

The Occupational Therapy Practice Framework-2 (OTPF-2) describes occupational therapy service delivery as a collaborative process between the client and the occupational

therapy practitioner.² This collaboration can occur in a variety of settings (e.g., hospitals, schools, community settings, home). Environment is an aspect of the domain of occupational therapy that can influence a client’s engagement in occupations. Environment is the “external physical and social environments that surround the client and in which the client’s daily life occupations occur” (p. 642).² Therefore, the setting, or physical context, in which occupational therapy intervention occurs plays a significant role in the delivery of services in terms of supporting or inhibiting the client’s performance.

Medical technology and cost control pressures have made it necessary for rehabilitation professionals to treat seriously ill clients early in their illness and for shorter periods. In the hospital setting, it is not unusual for occupational therapists to work with clients using interventions that include specialized medical equipment such as **catheters**, intravenous (IV) lines, monitoring devices, and ventilators. These circumstances increase the potential for injuries to clients. In addition to ethical obligations to provide safe and proper intervention, OT personnel can be held legally liable for negligence if a client is injured because staff failed to follow proper procedures or standards of care.⁶

This chapter reviews specific safety precautions for use with a variety of clients. It identifies precautions to consider when encountering equipment commonly used with clients. Guidelines for handling various emergency situations are reviewed. It is important to note that the chapter is only an overview and cannot substitute for training in specific procedures used in many facilities. In addition to following these procedures, it is incumbent upon the occupational therapist to teach clients and their families applicable techniques that can be followed at home.

Safety Recommendations for the Clinic

Prevention of accidents and subsequent injuries begins with consistent application of basic safety precautions for the clinic:

1. Wash your hands for at least 15 seconds before and after treating each client to reduce cross-contamination.⁴
2. Make sure space is adequate to maneuver equipment. Avoid placing clients where they may be bumped by equipment or passing personnel. Keep the area free from clutter.¹⁰
3. Do not attempt to transfer clients in congested areas or in areas where your view or movement is blocked.¹⁰
4. Routinely check equipment to ensure that it is working properly.
5. Make sure that the furniture and equipment in the clinic are stable. When not using items, store them out of the way of the treatment area.

6. Keep the floor free of cords, scatter rugs, litter, and spills. Ensure that the floors are not highly polished, because polished floors may be very slippery.¹⁰
7. Do not leave clients unattended. Follow federal guidelines for the proper use of restraint equipment (bed rails, belts, vests, etc.) to protect clients when they are not closely observed.
8. Have the treatment area and supplies ready before the client arrives.
9. Allow only properly trained personnel to provide client care.
10. Follow the manufacturer's and the facility's procedures for handling and storing potentially hazardous material. Make sure that such materials are marked and stored in a place that is in clear view. Do not store such items above shoulder height.
11. Clearly label emergency exits and evacuation routes.
12. Have emergency equipment, such as fire extinguishers and first aid kits, readily available.

Precautions With Special Equipment

Newly hired OT personnel need orientation and education regarding the types of medical equipment they are likely to encounter when treating clients. Before providing any intervention to a client at bedside, the OT should carefully review the medical chart to determine whether any specific instructions regarding movement precautions, positioning, or handling should be followed. For example, a client may need to follow a turning schedule and may be limited in the length of time allowed to remain in one position. Certain joint movements may be contraindicated, or special bed and wheelchair positioning requirements may need to be followed, such as with clients recovering from burn injury, spinal cord injury, stroke, hip replacement surgery, and so forth. Special handling techniques may be required when working with clients who have catheters, feeding tubes, IV lines, or special monitors. The various chapters throughout this book that address specific diagnoses will identify necessary precautions and handling recommendations.

Hospital Beds

OT personnel must be educated in the proper use of hospital beds to ensure client safety. The most commonly used hospital bed is electrically powered, but some are adjusted manually (cranked) or by hydraulic methods. All hospital beds are designed to make it easier to support the client and to change a client's position. Other, more specialized beds are needed for management of more complicated or more traumatic cases. Whatever type is used, the bed should be positioned so that the client is easily accessed and the therapist can use good body mechanics during mobility activities (see Chapter 11).

Most standard electrically adjustable beds are adjusted by means of electrical controls attached to the head or the foot of the bed or to a special cord that allows the client to operate the controls. The controls are marked according to their function and can be operated with the hand or foot. The entire bed can be raised and lowered, or upper and lower sections of the bed can be elevated or lowered to meet client needs. When the upper portion is raised 45 to 60 degrees, the client's position is referred to as **Fowler's position**.¹⁰ This commonly used position facilitates lung expansion, improves breathing, and decreases cardiac workload (as compared with supine lying). However, an important precaution for the OT to observe and address is that, in this position, the client may slide down in the bed, which increases shearing forces on tissues of the back.¹⁴

Side rails are attached to most beds as a protective measure. Some rails are lifted upward to engage the locking mechanism, whereas others are moved toward the upper portion of the bed until the locking mechanism is engaged. If a side rail is used for client security, the OT should be sure the rail is locked securely before leaving the client. The rail should be checked to ensure that it does not compress, stretch, or otherwise interfere with any IV or other tubing.

A rotating kinetic bed allows for realignment and stabilization of the client and places him/her in perpetual slow motion from side to side, which provides pressure relief and mobilization of respiratory secretions. The bed is constructed with hinged sections that can be removed to allow access to all areas of the body so that health care providers can provide necessary care and treatment.⁵ This bed is used most frequently with clients who have spinal cord injuries requiring immobilization. Another option is a turning frame (e.g., Stryker wedge frame), which has front and back frames that are covered with canvas. The support base allows elevation of the head or foot ends of the frame or of the entire bed. One person can easily turn the client horizontally from prone to supine or from supine to prone. The turning frame allows access to the client and permits the client to be repositioned without being removed from the frame.⁵ Because of the limited number of possible positions, the skin of clients using this type of bed should be monitored frequently.

The circular turning frame (circo-electric bed) has a front and a back frame attached to two circular supports. The frames on which the client is positioned move the client vertically from supine to prone or from prone to supine. The circular support frames are moved by an electric motor and can be stopped at any point within a 210-degree range.⁹ The client or another person can use a control switch to adjust the position. The circular turning bed is used with clients in traction, and to facilitate turning clients with severe burn injury. It provides the benefit of frequent position changes to relieve skin pressure. However, the client is still at risk for skin problems because of pressure forces that may occur when the bed is turned or rotated vertically. The bed can also serve as a standing frame when stopped in the

vertical position, which is helpful for clients who can benefit from increased weight bearing and stress to the bones and muscles of the lower extremity.⁵ However, clients may experience symptoms of motion sickness such as vertigo, nausea, or hypotension when being turned. Devices that turn the client, such as the circo-electric bed, are potentially dangerous. Personnel should be fully trained in correct operation, and patients need to be carefully monitored for signs of discomfort, dizziness, respiratory changes, and faintness following repositioning. This bed is contraindicated for use with clients with unstable spinal fractures or certain other pathologic conditions.⁵

The air-fluidized support bed (e.g., Clinitron [Hill-Rom, Batesville, Ind]) rests the client on an air-permeable mattress that contains millions of silicon-coated beads called *microspheres*.⁹ Heated, pressurized air flows through the beads to suspend a polyester cover that supports the client. When set in motion, the microspheres develop properties associated with fluids. Clients feel as if they are floating on a warm waterbed. The risk for skin problems is reduced because of minimal contact pressure between the client's body and the polyester sheet, which allows for even weight distribution and improved capillary blood flow to the skin. Friction and shearing of the skin are minimal. This bed is used with clients who have several infected lesions, or who require skin protection and whose position cannot be altered easily.⁵ Care should be taken to prevent puncturing the polyester cover (which would allow the microspheres to be expelled).

Ventilators

Ventilators (respirators) move gas or air into the client's lungs and are used to maintain adequate air exchange when normal respiration is decreased.⁹ Two frequently used types of ventilators are volume-cycled ventilators and pressure-cycled ventilators. Both ventilators deliver a predetermined volume of gas (air) during inspiration and allow for passive expiration.¹⁴ The gas delivered by the ventilator usually will be introduced into the client through an **endotracheal tube (ET)**, which is a catheter inserted through the nose or mouth into the trachea.⁹ When the tube is in place, the client is intubated. Insertion of the ET will prevent the client from talking. When the ET is removed, the client may complain of a sore throat and may have a distorted voice for a short period. It is important to avoid disturbing, bending, kinking, or occluding the tubing or accidentally disconnecting the ventilator tube from the ET. The client who uses a ventilator may participate in various bedside activities, including sitting and ambulation.¹³ Make sure the tubing is sufficiently long to allow the activity to be performed. Because the client will have difficulty talking, ask questions that can be answered with head nods or by other nonverbal means. A client using a ventilator may have a lower tolerance for activities and should be monitored for signs of respiratory distress such as a change in the respiration pattern, fainting, or blue lips.¹³

Monitors

Various monitors are used to observe the physiologic state of clients who need special care. Therapeutic activities can be performed by clients who are being monitored, provided that care is taken to prevent disruption of the equipment. Many of the units have auditory and visual signals that are activated by a change in the client's condition or position or by a change in the function of the equipment. It may be necessary for a nurse to evaluate and correct the cause of the alarm unless the OT has received special instruction.

The cardiac monitor provides a continuous check on the function of the client's heart, including electrical activity (electrocardiogram [ECG]), heart rate, blood pressure, and respiration rate.⁹ Acceptable or safe ranges for the three physiologic indicators can be set in the unit. An alarm is activated when the upper or lower limits of the ranges are exceeded, or if the unit malfunctions. A monitoring screen provides a graphic and digital display of the values so that healthcare staff can observe the client's responses to treatment.

The pulmonary artery catheter (PAC) (e.g., Swan-Ganz catheter) is a long, plastic IV tube that is inserted into a thoracic vein through the right side of the heart and is terminated in the pulmonary artery. It provides accurate and continuous measurements of pulmonary artery pressures and will detect subtle changes in the client's cardiovascular system, including responses to medications, stress, and activity.³ Activities, including OT interventions, can be performed with the PAC in place, providing they do not interfere with the location of insertion of the catheter. For example, if the catheter is inserted into the subclavian vein, elbow flexion should be avoided and shoulder motions restricted.

The intracranial pressure (ICP) monitor measures pressure exerted against the skull by brain tissue, blood, or cerebrospinal fluid (CSF).⁹ It is used to monitor ICP in clients with a closed head injury, cerebral hemorrhage, brain tumor, or overproduction of CSF. Some of the complications associated with this device are infection, hemorrhage, and seizures. Two of the more commonly used ICP monitoring devices are the ventricular catheter and the subarachnoid screw. Both are inserted in a hole drilled in the skull. Physical activities should be limited when these devices are in place. Activities that would cause a rapid increase in ICP, such as isometric exercises, should be avoided. Positions to avoid include neck flexion, hip flexion greater than 90 degrees, and the prone position. The client's head should not be lowered more than 15 degrees below horizontal. Care must be taken to avoid disturbing the plastic tube.

The **arterial monitoring line (A line)** is a catheter that is inserted into an artery to continuously and accurately measure blood pressure or to obtain blood samples without repeated needle punctures.³ OT intervention can be provided with an A line in place, but care should be taken to avoid disturbing the catheter and inserted needle.

Feeding Devices

Special feeding devices may be necessary to provide nutrition for clients who are unable to ingest, chew, or swallow food. Some of the more commonly seen devices are the **nasogastric (NG) tube**, the gastric tube, and **intravenous (IV) feedings**.

The NG tube is a plastic tube inserted through a nostril, terminating in the client's stomach. The tube may cause the client to have a sore throat or an increased gag reflex. Feeding training can be initiated while the NG tube is in place. However, care should be taken as the tube may desensitize the swallow mechanism.³ Caution should be used when moving the client's head and neck, especially in forward flexion, to prevent dislodging of the tube.

The gastric tube (G tube) is a plastic tube inserted through an incision in the client's abdomen directly into the stomach.³ The tube should not be disturbed or removed during the intervention.

Intravenous feeding, **total parenteral nutrition (TPN)**, or **hyperalimentation** devices permit infusion of large amounts of nutrients needed to promote tissue growth. A hyperalimentation device is used when a client is unable to eat or absorb nutrients through the gastrointestinal tract.³ A catheter is passed into a large vein (typically the subclavian vein) that empties directly into the heart. The catheter may be connected to a semipermanently fixed cannula, or sutured at the point of insertion. The OT should carefully observe the various connections to be certain they are secure before and after intervention. A disrupted or loose connection may result in the development of an air embolus, which could be life threatening.³

The system usually includes a specialized **feeding pump**, which will administer fluids and nutrients at a preselected, constant flow rate. An audible alarm will be activated if the system becomes imbalanced, or when the fluid source is empty.³ Intervention activities can be performed as long as the tubing is not disrupted, disconnected, or occluded, and as long as undue stress to the infusion site is prevented. Motions of the shoulder on the side of the infusion site may be restricted, especially abduction and flexion.

Most **intravenous (IV) lines** are inserted into superficial veins. Various sizes and types of needles or catheters are used, depending on the purpose of the IV therapy, the infusion site, the need for prolonged therapy, and site availability. Care should be taken during intervention to prevent any disruption, disconnection, or occlusion of the tubing. The infusion site should remain dry, the needle should remain secure and immobile in the vein, and no restraint should be placed above the infusion site.³ For example, a blood pressure cuff should not be applied above the infusion site. The total system should be observed, to ensure that it is functioning properly when intervention begins and ends. If the infusion site is in the antecubital area, the elbow should not be flexed. The client who ambulates with an IV line in place should be instructed to grasp the IV support pole so that the infusion site will be at heart level.³ If the

infusion site is allowed to hang lower, blood flow may be affected. Similar procedures to maintain the infusion site in proper position should be followed when the client is treated while in bed or at a treatment table. Activities involving elevation of the infusion site above the level of the heart for a prolonged period should be avoided. Problems related to the IV system should be reported to nursing personnel. Simple procedures such as straightening the tubing or removing an object that is occluding the tubing may be performed by the properly trained therapist.

Catheters

A urinary catheter is used to remove urine from the bladder when the client is unable to satisfactorily control retention or release.⁹ Urine is drained through plastic tubing into a collection bag, bottle, or urinal. Any form of trauma, disease, condition, or disorder affecting neuromuscular control of the bladder sphincter may necessitate the use of a urinary catheter. The catheter may be used temporarily or for the remainder of the client's life.

A urinary catheter can be applied internally (indwelling catheter) or externally. Female clients require an indwelling catheter inserted through the urethra and into the bladder. Males may use an external catheter. A condom catheter is applied over the shaft of the penis and is held in place by an adhesive applied to the skin or by a padded strap or tape encircling the proximal shaft of the penis. The condom is connected to a drainage tube and a urine collection bag.³

When clients with urinary catheters are receiving OT intervention, several precautions are important. Disruption or stretching of the drainage tube should be prevented, and no tension should be placed on the tubing or the catheter. The urine collection bag must not be placed above the level of the bladder for longer than a few minutes to avoid backflow of urine into the bladder or kidneys (if indwelling catheter) or soiling of the client (if external catheter). The bag should not be placed in the client's lap when the client is being transported. The production, color, and odor of the urine should be observed. The following observations should be reported to a physician or nurse: foul-smelling, cloudy, dark, or bloody urine, or a reduction in the flow or production of urine. The collection bag must be emptied when it is full.³

Infection is a major complication for persons using catheters, especially for those using indwelling catheters. Everyone involved with the client should maintain cleanliness during treatment. The tubing should be replaced or reconnected only by those properly trained. Treatment settings in which clients with catheters are routinely treated have specific protocols for catheter care.³

Two types of internal catheters that are frequently used are the Foley catheter and the suprapubic catheter. The Foley catheter is a type of indwelling catheter that is held in place in the bladder by a small balloon inflated with air, water, or sterile saline solution. For removal of the catheter, the balloon is deflated and the catheter is withdrawn. The

suprapubic catheter is inserted directly into the bladder through incisions in the lower abdomen and the bladder. The catheter may be held in place by adhesive tape, but care should be taken to avoid its removal, especially during self-care activities.³ Catheter application and bladder management are activities of daily living (ADL) that are frequently taught to clients as part of a comprehensive OT intervention program (see Chapters 10 and 36 for examples).

Infection Control

Infection control procedures are used to prevent the spread of disease and infection among clients, health care workers, and others. They are designed to interrupt or establish barriers to the infection cycle. In 1996, the **Centers for Disease Control and Prevention (CDC)** published *Guidelines for Isolation Precautions in Hospitals*.

Universal Precautions (UP) were established to protect health care workers and the clients they serve from infectious agents such as the human immunodeficiency virus (HIV) and diseases such as acquired immunodeficiency syndrome (AIDS), hepatitis B, and hepatitis C. UP placed an emphasis on preventing the transmission of **pathogens** (infectious microorganisms) through contact with blood and bodily fluids.¹² The CDC revised and developed additional guidelines for a system of isolation, called *body substance isolation (BSI)*, which focused on isolating moist and potentially infectious body substances (blood, feces, urine, sputum, saliva, wound drainage, and other body fluids) from all patients.¹² These guidelines recommended the use of **Standard Precautions**, which synthesized the primary features of BSI and UP. Standard Precautions apply to blood, all bodily secretions and fluids, mucous membranes, and nonintact skin (Box 9-1 and Figure 9-1).¹²

The most recent revision to the CDC guidelines (2007) recommends the use of two tiers of precautions to prevent transmission of infectious agents: Standard Precautions and **Transmission-Based Precautions**.¹² “Standard Precautions are intended to be applied to the care of all patients in all healthcare settings, regardless of the suspected or confirmed presence of an infectious agent. Implementation of Standard Precautions constitutes the primary strategy for the prevention of healthcare-associated transmission of infectious agents among patients and healthcare personnel” (p. 66).¹² Standard Precautions include hand hygiene; use of protective clothing such as gloves, gowns masks, or eye protection, depending on anticipated exposure; and safe injection practices. Specific recommendations for each area of the Standard Precautions are detailed in the CDC guidelines. Key features of these recommendations are summarized in Tables 9-1 and 9-2. Transmission-Based Precautions are additional standards that are implemented with clients who are known to be infected with infectious agents and require additional control measures to effectively prevent transmission.¹² The new standards of the CDC also reflect current trends in the transition of health care delivery from

Box 9-1

Summary of Standard Precautions

1. Use extreme care to prevent injuries caused by sharp instruments.
2. Cover minor, nondraining, noninfected skin lesions with an adhesive bandage.
3. Report infected or draining lesions and weeping dermatitis to your supervisor.
4. Avoid personal habits (e.g., nail biting) that increase the potential for oral mucous membrane contact with body surfaces.
5. Perform procedures involving body substances carefully to minimize splatters.
6. Cover environmental surfaces with moisture-proof barriers whenever splattering with body substances is possible.
7. Wash hands regularly, whether or not gloves are worn.
8. Avoid unnecessary use of protective clothing. Use alternate barriers whenever possible.
9. Wear gloves to touch the mucous membrane or the nonintact skin of any client, and whenever direct contact with body substances is anticipated.
10. Wear protective clothing (e.g., gown, mask, and goggles) when splashing of body substances is anticipated.
11. Ensure that the hospital has procedures for care, cleaning, and disinfection of environmental surfaces and equipment.
12. Handle and process soiled linens in a manner that minimizes the transfer of microorganisms to other patients and environments.
13. Handle used patient care equipment appropriately to prevent transfer of infectious microorganisms. Ensure that reusable equipment is thoroughly and appropriately cleaned.

■ **TABLE 9-1** | Warning Signs and Symptoms of Insulin-Related Illnesses

	Insulin Reaction (Insulin Shock)	Ketoacidosis (Diabetic Coma)
Onset	Sudden	Gradual
Skin	Moist, pale	Dry, flushed
Behavior	Excited, agitated	Drowsy
Breath odor	Normal	Fruity
Breathing	Normal to shallow	Deep, labored
Tongue	Moist	Dry
Vomiting	Absent	Present
Hunger	Present	Absent
Thirst	Absent	Present

Universal Precautions apply to blood, visibly bloody fluid, semen, vaginal secretions, tissues and to cerebrospinal, synovial, pleural, peritoneal, pericardial and amniotic fluids.

FIGURE 9-1 Universal blood and body fluid precautions.
(Courtesy Brevis Corp, Salt Lake City, Utah.)

primarily acute hospital settings to other settings (e.g., long-term care, home care). The new recommendations “can be applied in all healthcare settings using common principles of infection control practice, yet can be modified to reflect setting-specific needs” (p. 7).¹² Additionally, the term *nosocomial infection* (i.e., hospital-acquired infection) has been replaced by *health care-associated infection (HIA)* “to reflect the changing patterns in healthcare delivery and difficulty in determining the geographic site of exposure to an infectious agent and/or acquisition of infection” (p. 7).¹²

The **Occupational Safety and Health Administration (OSHA)** issues regulations to protect the employees of health care facilities. All health care settings must do the following to comply with federal regulations:

1. Educate employees on methods of transmission and on prevention of hepatitis B, HIV, and other infections.
2. Provide safe and adequate protective equipment and teach employees where the equipment is located and how to use it.
3. Teach employees about work practices used to prevent occupational transmission of disease, including, but not limited to, Universal Precautions, proper handling of client specimens and linens, proper cleaning of body fluid spills (Figure 9-2), and proper waste disposal.
4. Provide proper containers for the disposal of waste and sharp items, and teach employees the color coding system used to distinguish infectious waste.
5. Post warning labels and biohazard signs (Figure 9-3).

6. Offer the hepatitis B vaccine to employees who are at substantial risk of occupational exposure to the hepatitis B virus.
7. Provide education and follow-up care to employees who are exposed to communicable disease.

OSHA has also outlined the responsibilities of health care employees. These responsibilities include the following:

1. Use protective equipment and clothing provided by the facility whenever the employee contacts, or anticipates contact with, body fluids.
2. Dispose of waste in proper containers, applying knowledge and understanding of the handling of infectious waste, and using color-coded bags or containers.
3. Dispose of sharp instruments and needles into proper containers without attempting to recap, bend, break, or otherwise manipulate them before disposal.
4. Keep the work environment and the client care area clean.
5. Wash hands immediately after removing gloves and at any other times mandated by hospital or agency policy.
6. Immediately report any exposures such as needle sticks or blood splashes or any personal illnesses to immediate supervisor, and receive instruction about any further follow-up action.

Although it is impossible to eliminate all pathogens from an area or object, the likelihood of infection can be greatly

TABLE 9-2 | Recommendations for Application of Standard Precautions in the Care of All Patients in All Health Care Settings

Component	Recommendations
Hand hygiene	After touching blood, body fluids, secretions, excretions, contaminated items; immediately after removing gloves; between patient contacts
PERSONAL PROTECTIVE EQUIPMENT (PPE)	
Gloves	For touching blood, body fluids, secretions, excretions, contaminated items; for touching mucous membranes and nonintact skin
Gown	During procedures and patient care activities when contact of clothing/exposed skin with blood/body fluids, secretions, and excretions is anticipated
Mask, eye protection (goggles), face shield	During procedures and patient care activities likely to generate splashes or sprays of blood, body fluids, secretions, especially suctioning, endotracheal intubation
Soiled patient care equipment	Handle in a manner that prevents transfer of microorganisms to others and to the environment; wear gloves if visibly contaminated; perform hand hygiene.
Environmental control	Develop procedures for routine care, cleaning, and disinfection of environmental surfaces, especially frequently touched surfaces in patient care areas.
Textiles and laundry	Handle in a manner that prevents transfer of microorganisms to others and to the environment.
Needles and other sharps	Do not recap, bend, break, or hand-manipulate used needles; if recapping is required, use a one-handed scoop technique only; use safety features when available; place used sharps in puncture-resistant container.
Patient resuscitation	Use mouthpiece, resuscitation bag, or other ventilation devices to prevent contact with mouth and oral secretions.
Patient placement	Prioritize for single-patient room if patient is at increased risk of transmission, is likely to contaminate the environment, does not maintain appropriate hygiene, or is at increased risk for acquiring infection or developing adverse outcomes following infection.
Respiratory hygiene/cough etiquette (source containment of infectious respiratory secretions in symptomatic patients, beginning at initial point of encounter [e.g., triage and reception areas in emergency departments and physician offices])	Instruct symptomatic persons to cover mouth/nose when sneezing/coughing; use tissues and dispose of in no-touch receptacle; observe hand hygiene after soiling of hands with respiratory secretions; wear surgical mask if tolerated or maintain spatial separation >3 feet if possible.

From Siegel JD, Rhinehart E, Jackson M, Chiarello L, Healthcare Infection Control Practices Advisory Committee: 2007 guideline for isolation precautions: preventing transmission of infectious agents in healthcare settings. Available at: <http://www.cdc.gov/hicpac/pdf/isolation2007.pdf>

reduced. The largest source of preventable client infection is contamination from the hands of health care workers. Hand hygiene (Box 9-2 and Figure 9-4) and the use of gloves are the most effective barriers to the infection cycle.^{4,12} The use of gloves does not eliminate the need for hand-washing, and vice versa. Latex gloves provide the best protection from infectious materials. However, many individuals have latex allergies, so nonlatex gloves should be used for activities that are not likely to involve contact with infectious materials (e.g., food preparation, routine housekeeping, general maintenance).⁵ The CDC also recommends the use of alcohol-based hand rubs as an acceptable alternative

to hand-washing. Alcohol-based hand rubs are fast acting, cause minimal skin irritation, and significantly reduce the presence of microorganisms on the skin.⁴

In the clinic, general cleanliness and proper control of heat, light, and air are important for infection control. Spills should be cleaned up promptly. Work areas and equipment should be kept free from contamination.

To decontaminate is to “remove, inactivate, or destroy blood-borne pathogens on a surface or item to the point where they are no longer capable of transmitting infectious particles and the surface or item is rendered safe for handling, use, or disposal.”¹² Items to be sterilized or

FIGURE 9-2 Spills of body fluids must be cleaned up by a gloved employee using paper towels, which should then be placed in an infectious waste container. Afterward, 5.25% sodium hypochlorite (household bleach) diluted 1:10 should be used to disinfect the area.

(From Young AP: *Kinn's the medical assistant*, ed 11, St Louis, 2011, Elsevier, Inc.)

FIGURE 9-3 Biohazard label.

(From Young AP: *Kinn's the medical assistant*, ed 11, St Louis, 2011, Elsevier, Inc.)

decontaminated should first be cleaned thoroughly to remove any residual matter. Sterilization is used to destroy all forms of microbial life, including highly resistant bacterial spores. An **autoclave** is used to sterilize items by steam under pressure. Ethylene oxide, dry heat, and immersion in chemical disinfectants are other methods of sterilization.³

Box 9-2

Technique for Effective Hand-Washing

1. Remove all jewelry, except plain band-type rings. Remove watch or move it up. Provide complete access to area to be washed.
2. Approach the sink and avoid touching the sink or nearby objects.
3. Turn on the water and adjust it to a lukewarm temperature and a moderate flow to prevent splashing.
4. Wet your wrists and hands with your fingers directed downward, and apply approximately 1 teaspoon of liquid soap or granules.
5. Begin to wash all areas of your hands (palms, sides, and backs), fingers, and knuckles, and between fingers, using vigorous rubbing and circular motions (Figure 9-4, A). If wearing a band, slide it down the finger a bit and scrub the skin underneath it. Interlace fingers and scrub between each finger.
6. Wash for at least 15 seconds, keeping the hands and forearms at elbow level or below, with hands pointed down. Wash longer if you have treated a client known to have an infection.
7. Rinse hands well under running water.
8. Wash wrists and forearms as high as contamination is likely.
9. Rinse hands, wrists, and forearms under running water (Figure 9-4, B).
10. Use an orangewood stick or nail brush to clean under each fingernail at least once a day when starting work and each time hands are highly contaminated. Rinse nails well under running water (Figure 9-4, C).
11. Dry your hands, wrists, and forearms thoroughly with paper towels. Use a dry towel for each hand. The water should continue to flow from the tap as you dry your hands.
12. Use another dry paper towel to turn the water faucet off (Figure 9-4, D). Discard all towels in an appropriate container.
13. Use hand lotion as necessary.

Modified from Zakus SM: *Clinical procedures for medical assistants*, ed 3, St Louis, 1995, Mosby.

A variety of disinfectants may be used to clean environmental surfaces and reusable instruments. When liquid disinfectants and cleaning agents are used, gloves should be worn to protect the skin from repeated or prolonged contact. The CDC, local health department, or hospital infection control department can provide information about the best product and method to use.

Instruments and equipment used to treat a client should be cleaned or disposed of according to institutional or agency policies and procedures. Contaminated reusable equipment should be placed carefully in a container, labeled, and returned to the appropriate department for sterilization. Contaminated disposable items should be placed carefully in a container, labeled, and disposed of.

FIGURE 9-4 **A**, Hand-washing technique. Create a lather with soap. Keep hands pointed down. **B**, Rinse hands well, keeping fingers pointed down. **C**, Use a paper towel to dry hands thoroughly. **D**, After drying your hands, turn water faucet off, using a dry paper towel.
 (From Young AP: *Kinn's the medical assistant*, ed 11, St Louis, 2011, Elsevier, Inc.)

Contaminated or soiled linen should be disposed of with minimal handling, sorting, and movement. It can be bagged in an appropriate bag and labeled before transport to the laundry, or the bag can be color-coded to indicate the type or condition of linen it contains. Other contaminated items such as toys, magazines, personal hygiene articles, dishes, and eating utensils should be disposed of or disinfected. They should not be used by others until they have been disinfected.

OT Practice Note

Therapists should routinely clean and disinfect personal items such as pens, keys, and clipboards, because these objects are touched frequently and may become contaminated.

Isolation Systems

Isolation systems are designed to protect a person or object from becoming contaminated or infected by transmissible pathogens. Various isolation procedures are used in different institutions. It is important for all health care workers to understand and follow the isolation approach used in their facilities so protection can be ensured. The CDC established Transmission-Based Precautions, which are intended for patients documented or suspected of being infected with highly transmissible or epidemiologically important pathogens. “Transmission-Based Precautions are used when the route(s) of transmission is (are) not completely interrupted using Standard Precautions alone” (p. 69).¹² Three types of Transmission-Based Precautions may be used singly or in combination to control infectious transmission: contact precautions, droplet precautions, and airborne precautions. The CDC provides specific recommendations for each infection control measure. In addition, Appendix A of the 2007 guidelines provides a comprehensive list of the types

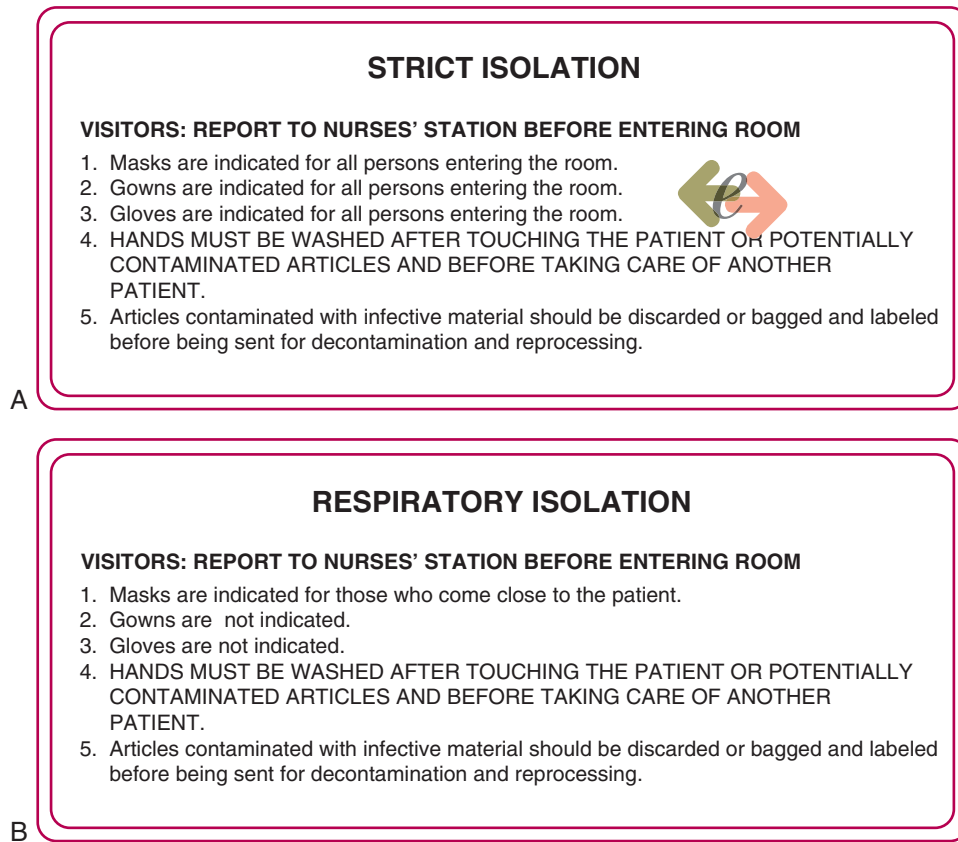

FIGURE 9-5 A, Strict isolation procedures sign. Card will be color-coded yellow and will be placed on or next to the door of the client's room. B, Respiratory isolation procedures sign. Card will be color-coded blue and will be placed on or next to the door of the client's room.

of precautions (e.g., standard, contact, airborne, droplet) recommended for selected infections and conditions.¹²

When Transmission-Based Precautions are needed, a client is usually isolated from other clients and the hospital environment because he or she has a transmissible disease. Isolation involves placing the client in a room alone or with one or more clients with the same disease to reduce the possibility of transmitting the disease to others. Specific infection control techniques must be followed by all who enter the client's room. These requirements are based on the type of infectious organism and common routes of transmission (i.e., airborne, direct or indirect physical contact, and droplets). Specific instructions are listed on a color-coded card and are placed on or next to the door of the client's room. Strict isolation and respiratory isolation procedures are shown in Figure 9-5. Protective clothing, including gown, mask, cap, and gloves, may be needed. When leaving the client, the caregiver must dispose of protective clothing before leaving the room and must dispose of it in an appropriately designated area or container for storage, washing, decontamination, or disposal. Examples of diseases that require Transmission-Based Precautions include tuberculosis, severe acute respiratory syndrome (SARS), *Clostridium difficile*, chicken pox, measles, and meningitis.¹²

Occasionally, a client's condition (e.g., burns, systemic infection) makes him or her more susceptible to infection. This client may be placed in protective isolation. In this approach, persons entering the client's room may have to wear protective clothing to prevent the transmission of pathogens to the client. The sequence and method of donning the protective garments are more important than the sequence used to remove them.

Health care-associated infections continue to be a significant problem in a variety of health care delivery settings.¹² It is critical that OT personnel be given proper education and training in infection control standards to prevent the spread of unnecessary infections.

Incidents and Emergencies

Occupational therapists should be able to respond to a variety of medical emergencies and to recognize when it is better to get assistance from the most qualified individual available, such as a doctor, emergency medical technician, or nurse. Securing such assistance should be relatively easy in a hospital but may require an extended period before response if the OT intervention is conducted in a client's home or an outpatient clinic. It is a good idea to keep emergency telephone numbers readily available. The

therapist will need to determine at the time of the incident whether it is wiser to ask for assistance before or after beginning emergency care.

Ethical Considerations

In most cases, it is best to call for assistance before initiating emergency care, unless delay is life threatening to the client.

All OTs should be certified in **cardiopulmonary resuscitation (CPR)** and should have received basic first aid training. Training and certification can be obtained through organizations such as the American Heart Association (www.americanheart.org) and the American Red Cross (www.redcross.org).

Consistently following safety measures will prevent many accidents. However, the therapist should always be alert to the possibility of an injury and should expect the unexpected to happen. Most institutions have specific policies and procedures to follow. In general, the therapist should do the following when an injury to a client occurs:

1. Ask for help. Do not leave the client alone. Prevent further injury to the client and provide emergency care.
2. When the emergency is over, document the incident according to the institution's policy. Do not discuss the incident with the client or significant others or express information to anyone that might indicate negligence.¹¹
3. Notify the supervisor of the incident and file the incident report with the appropriate person within the organization.

Falls

The risk of falling is always present when functional mobility is addressed with clients. The OT can reduce the risk of falling by carefully preparing the environment before initiating intervention. This includes use of a gait belt during mobility activities, clearing the environment of potential hazards, and having a wheelchair or chair nearby to pull into position for clients who might be prone to falling. The therapist can prevent injuries from falls by remaining alert and reacting quickly when clients lose their balance. Proper guarding techniques must be practiced. In many instances, it is wise to resist the natural impulse to keep the client upright. Instead, the therapist can carefully assist the client to the floor or onto a firm object.

If a client begins to fall forward, the following procedure should be used: Restrain the client by firmly holding the gait belt. Push forward against the pelvis and pull back on the shoulder or anterior chest. Help the client stand erect once it is determined that no injury has occurred. The client

may briefly lean against you for support. If the client is falling too far forward to be kept upright, guide the client to reach for the floor slowly. Slow the momentum by gently pulling back on the gait belt and the client's shoulder. Step forward as the client moves toward the floor. Tell the client to bend the elbows when the hands contact the floor to help cushion the fall. The client's head should be turned to one side to avoid injury to the face.

If the client begins to fall backward, the following procedure should be used: Rotate your body so one side is turned toward the client's back, and widen your stance. Push forward on the client's pelvis and allow the client to lean against your body. Then, assist the client to stand erect. If the client falls too far backward, to stay upright, continue to rotate your body until it is turned toward the client's back, and widen your stance. Instruct the client to briefly lean against your body or to sit on your thigh. You may need to lower the client into a sitting position on the floor using the gait belt and good body mechanics.

Burns

Generally, only minor, first-degree burns are likely to accidentally occur in occupational therapy. These can be treated with basic first aid procedures. Skilled personnel should be contacted for immediate care if the burn has any charred or missing skin or shows blistering. The following steps should be taken for first-degree burns in which the skin is only reddened⁷:

1. Rinse or soak the burned area in cold (not iced) water.
2. Cover with a clean or sterile dressing.
3. Do not apply any cream, ointment, or butter to the burn because this will mask the appearance and may lead to infection or a delay in healing.
4. Report the incident, so that the injury can be evaluated by a physician.

Bleeding

A laceration may result in minor or serious bleeding. The objectives of first aid treatment are to prevent contamination of the wound and to control bleeding. The following steps should be taken to stop the bleeding:

1. Wash your hands and apply protective gloves. Continue to wear protective gloves while treating the wound.
2. Place a clean towel or a sterile dressing over the wound, and apply direct pressure to the wound. If no dressing is available, use your gloved hand.
3. Elevate the wound above the level of the client's heart to reduce blood flow to the area.
4. In some instances, the wound can be cleansed with an **antiseptic** or by rinsing it with water.
5. Encourage the client to remain quiet and to avoid using the extremity.

6. If arterial bleeding occurs (demonstrated by spurting blood), it may be necessary to apply intermittent, direct pressure to the artery, above the level of the wound. The pressure point for the brachial artery is on the inside of the upper arm, midway between the elbow and the armpit. The pressure point for the femoral artery is in the crease of the hip joint, just to the side of the pubic bone.
7. Do not apply a tourniquet unless you have been trained to do so.

Shock

Clients may experience shock as a result of excessive bleeding, sepsis, and respiratory distress; as a reaction to the change from a supine to an upright position; or as a response to excessive heat or anaphylaxis (severe allergic reaction). Shock causes a drop in blood pressure and inefficient cardiac output, resulting in inadequate perfusion of organs and tissues. Signs and symptoms of shock include pale, moist, and cool skin; shallow and irregular breathing; dilated pupils; a weak or rapid pulse; dizziness or nausea; and altered level of consciousness.⁷ Shock should not be confused with fainting, which would result in a slower pulse, paleness, and perspiration. Clients who faint generally will recover promptly if allowed to lie flat. If a client exhibits symptoms of shock, the following actions should be taken:⁷

1. Get medical assistance as soon as possible, as shock can be life threatening.
2. Try to determine the cause of shock and correct it if possible. Monitor the client's blood pressure, breathing, and pulse rate.
3. Place the person in a supine position, with head slightly lower than the legs. If head and chest injuries are present, or if respiration is impaired, it may be necessary to keep the head and chest slightly elevated.
4. Do not add heat, but prevent loss of body heat if necessary by applying a cool compress to the client's forehead and covering the client with a light blanket.
5. Do not allow exertion. Keep the client quiet until emergency medical help arrives.

Seizures

Seizures may be caused by a specific disorder, brain injury, or medication. The OT should be able to recognize a seizure and should take appropriate action to keep the client from getting hurt. A client having a seizure will usually become rigid for a few seconds and then will begin to convulse with an all-over jerking motion. The client may turn blue and may stop breathing for up to 50 to 70 seconds. A client's sphincter control may be lost during or at the conclusion of the seizure, so the client may void urine or feces involuntarily.⁷ When a client shows signs of entering a seizure, the following steps should be taken:⁷

1. Place the person in a safe location, and position away from anything that might cause injury. Do not attempt to restrain or restrict the convulsions.
2. Loosen clothing around the person's neck to assist in keeping the client's airway open.
3. Do not insert any objects into the person's mouth; this can cause injury.
4. Remove sharp objects (glasses, furniture, and other objects) from around the person to prevent injury.
5. When the convulsions subside, lay the person on his or her side to maintain an open airway and to prevent the person from aspirating any secretions.
6. After the convulsions cease, have the client rest. He or she may experience confusion for a period of time. It may be helpful to cover the client with a blanket or screen to provide privacy.
7. Get medical help.

Insulin-Related Illnesses

Many clients seen in OT have insulin-related episodes. These episodes can occur as the result of severely inadequate insulin levels (hyperglycemia) or from excessive insulin (hypoglycemia).⁷ It is very important for the OT to be able to differentiate between the conditions of hypoglycemia (insulin reaction) and hyperglycemia (ketoacidosis), which can lead to diabetic coma, as shown in Table 9-1. Both conditions can result in loss of consciousness, but medical intervention for each condition is very different.

An insulin reaction (also called *insulin shock*) can be caused by too much systemic insulin, the intake of too little food or sugar, or too much physical activity.⁷ If the client is conscious, some form of sugar (e.g., candy, orange juice) should be provided. If the client is unconscious, glucose may have to be provided intravenously. The client should rest, and all physical activity should be stopped. This condition is not as serious as ketoacidosis, but the client should be given the opportunity to return to a normal state as soon as possible.

Hyperglycemia can develop when a person with diabetes fails to take enough insulin or deviates significantly from a prescribed diet. Ketoacidosis and dehydration occur, and can lead to a diabetic coma and eventual death if not treated.⁷ This should be considered a medical emergency requiring prompt action, including assistance from qualified personnel. The client should not be given any form of sugar. Usually, an injection of insulin is needed, followed by IV fluids and salt. A nurse or physician should provide care as quickly as possible.

Respiratory Distress

Dyspnea control postures may be used to reduce breathlessness in clients in respiratory distress.⁸ The client must be responsive and must have an unobstructed airway. The high-Fowler's position (Figure 9-6, A) may be used for clients in bed. The head of the bed should be in an upright

FIGURE 9-6 A, High-Fowler's position. B, Orthopneic position.

position at a 90-degree angle. If available, a footboard should be used to support the client's feet. The orthopneic position (Figure 9-6, B) may be used for clients who are sitting or standing. In either case, the client bends forward slightly at the waist and supports the upper body by leaning the forearms on a table or counter. Pursed-lip breathing, which is a breathing pattern of inhaling through the nose and slowly exhaling through pursed lips, can help decrease dyspnea and the respiratory rate⁸ (see Chapter 44 for additional suggestions).

Choking and Cardiac Arrest

All health care practitioners should be trained to treat clients who are choking or suffering from cardiac arrest. Cardiopulmonary resuscitation (CPR) "is a series of life-saving actions that improve the chance of survival following cardiac arrest" (S.676).¹⁵ CPR certification involves instruction in recognizing a cardiac arrest, activating the emergency response system, performing specific CPR techniques, and using an automatic external defibrillator (AED). In addition, training in recognizing and providing intervention when an individual is choking is provided. In 2010, the American Heart Association introduced new standards for the performance of CPR and emergency cardiovascular care. Previous guidelines comprised three basic steps to CPR: establish airway, provide mouth-to-mouth resuscitation (breathing), and provide chest compressions (e.g., A-B-C). The new guidelines advise initiating chest compressions first, followed by establishing the airway, and then breathing (e.g., C-A-B) (Figure 9-7).¹⁵ Specific certification training courses are offered by both the American Heart

Association and the American Red Cross. The following information is presented as a reminder of the basic techniques and is not meant to be substituted for training.

The urgency of choking cannot be overemphasized. Immediate recognition and proper action are essential. When assisting a conscious adult or a child who is older than 1 year, the following steps should be taken¹⁵:

1. Ask the client, "Are you choking?" If the client can speak or cough effectively, do not interfere with the client's own attempts to expel the object.
2. If the client is unable to speak, cough, or breathe, check the mouth and remove any visible foreign object.
3. If the client is unable to speak or cough, position yourself behind the client. Clasp your hands over the client's abdomen, slightly above the umbilicus but below the diaphragm.
4. Use the closed fist of one hand, covered by your other hand, to give three or four abrupt thrusts against the person's abdomen by compressing the abdomen in and up forcefully (also known as the Heimlich maneuver). Continue to apply the thrusts until the obstruction becomes dislodged or is relieved, or the person becomes unconscious. It is no longer recommended that a rescuer perform a finger sweep to remove the object.
5. Seek medical assistance.

When assisting an adult or a child who is older than 1 year who appears to be unconscious, the following steps should be taken¹⁵:

FIGURE 9-7 New guidelines from the American Heart Association (C-A-B).

1. Ensure that it is safe for you to intervene (no hazards or risky environmental conditions).
2. Activate the emergency response system (call for help, or call 9-1-1). Get an AED (defibrillator), if available. If two persons are available, one should call for help and get the AED, while the other individual initiates CPR.
3. Attempt to awaken or arouse the individual.
4. If the individual is unresponsive, place the person in a supine position on a firm surface.
5. Initiate chest compressions. Kneel next to the client, and place the heel of one hand on the inferior portion of the sternum superior to the xiphoid process (approximately in line with the nipples). Put your other hand over your first hand with the fingers interlaced. Position your shoulders directly over the client's sternum, keep your elbows extended, and press down firmly, depressing the sternum approximately 2 inches with each compression. Relax after each compression, allowing the chest to fully recoil after each compression, but do not remove your hands from the sternum. The relaxation and compression phases should be equal in duration. Compressions should be applied at a rate of approximately 100 per minute.¹⁵
6. If you are not trained in CPR, continue to perform chest compressions until help arrives or the victim awakens.
7. If you are trained in CPR, perform 30 chest compressions, then open the victim's airway using the head-tilt, chin-lift method.
8. Check for respiration by observing the chest or abdomen for movement, listen for sounds of breathing, and feel for breath by placing your cheek close to the person's mouth. If no sign of breath is present, the client is not breathing, and you should initiate breathing techniques.
9. Pinch the client's nose closed and maintain the head tilt to open the airway. Place your mouth over the client's mouth and form a seal with your lips. Perform two full breaths. Your breaths should be strong enough to make the victim's chest rise. Some persons prefer to place a clean cloth over the client's lips before initiating mouth-to-mouth respirations. If available, a plastic CPR device can be used to decrease contact between the caregiver's mouth and the client's mouth and any saliva or vomitus.
10. Evaluate for circulation by palpating the carotid artery for a pulse. Sometimes it can be difficult to locate a pulse, so also observe the client for signs of life—breathing, movement, consciousness. If no pulse or signs of consciousness are noted, you must return to performing external chest compressions.
11. If you are performing CPR procedures without assistance, you should repeat 30 chest compressions followed by 2 breaths. Continue this sequence

(30 compressions/2 rescue breaths) for 5 cycles, then stop to recheck the victim for breathing (chest rising, breath sounds) and evaluate for circulation (check carotid pulse). If the victim still is not breathing, resume CPR. Repeat this process, checking for breathing and pulse every 5 cycles, until qualified assistance arrives, or the client is able to sustain independent respiration and circulation.¹⁵ In all instances, the client will require hospitalization and evaluation by a physician.

12. If you have access to an AED, continue to perform CPR until you can attach the chest pads and turn the machine “on.” If you are alone and you observed the victim collapse, put the AED on immediately. If you did not observe the collapse, attach the AED after approximately 1 minute of CPR. The AED will analyze the victim’s heart for rhythm and will provide a shock if necessary. The AED machine provides auditory instructions for operation. After placement of the chest pads, it will analyze the victim’s heart for rhythm and will direct the rescuer to provide a shock or to continue CPR.¹⁵

(Note: Extreme care must be taken to open the airway of a person who may have experienced a cervical spine injury. In such cases, use the chin lift, but avoid the head tilt. If the technique does not open the airway, the head should be tilted slowly and gently until the airway is open.)

These procedures are appropriate to use for adults and for children 8 years of age and older. CPR is contraindicated if clients have clearly expressed their desire for “do not resuscitate” (DNR). This information should be clearly documented in the medical chart. A pamphlet or booklet containing diagrams and instructions for CPR techniques can be obtained from most local offices of the American Heart Association or from a variety of Websites.

Summary

All occupational therapy personnel have a legal and professional obligation to promote safety for self, the client, visitors, and others. The OT should be prepared to react to emergency situations quickly, decisively, and calmly. The consistent use of safe practices helps reduce accidents for both clients and workers and reduces the length and cost of treatment.

Review Questions

1. Why is it important to teach the client and significant others guidelines for handling various emergency situations?
2. Describe at least four behaviors that you can adopt to improve client safety.
3. Why is it important to review a client’s chart before initiating an intervention?

Threaded Case Study Donna, Part 2

To adequately prepare the OT clinic as a safe environment for clients and staff, clear policies and procedures pertaining to client safety, medical emergencies, client safety, infection control, and precautions with special equipment need to be developed and implemented. In the case study presented at the beginning of this chapter, Donna, the Director of OT Services, was responsible for developing such policies and procedures. It should be mandatory for all OT personnel to become certified in CPR and first aid. Employee manuals can be produced that orient staff to general safety procedures and infection control standards. Furthermore, in-service education should be developed for newly hired personnel that familiarizes them with the types of specialized medical equipment that occupational therapy personnel are likely to encounter in their interventions with clients.

Many resources are available that can assist Donna in establishing these policies and procedures. The Centers for Disease Control and Prevention (www.cdc.gov), the Occupational Safety and Health Administration (www.OSHA.gov), and the National Institutes of Health (www.NIH.gov) are government organizations that provide the most current information pertaining to health standards, infection control, medical research, and workplace safety. Information on first aid, choking, and CPR can be obtained from most local offices of the American Heart Association and from the American National Red Cross. In addition, information on emergency procedures may be found at a variety of Websites.

4. What types of activities are appropriate when providing an intervention to a client who is ventilator dependent? What precautions must be taken during such activities?
5. Define the following: IV line, A line, NG tube, TPN or hyperalimentation, and catheter.
6. Describe Standard Precautions.
7. Why is it important to follow Standard Precautions with all clients?
8. Demonstrate the proper technique for hand-washing.
9. How should you respond to a client emergency?
10. Distinguish between an insulin reaction and ketoacidosis (diabetic coma). What is the appropriate medical intervention for each condition?
11. Describe how you would help a client who is falling forward and one who is falling backward.
12. Which emergency situations might require getting advanced medical assistance, and which situations could a therapist handle alone?

Client-centered approach

Levels of independence

Home evaluation

Accessibility

■ **Learning Objectives** *After studying this chapter, the student or practitioner will be able to do the following:*

1. Describe activities of daily living (ADLs) and instrumental activities of daily living (IADLs), and explain how ADLs and IADLs relate to the OTPF-2.
2. Explain why it is important to consider the cultural, personal, temporal and virtual contexts when performing ADL and IADL assessments and training. Give examples of specific cultural, personal, temporal, and virtual contexts that an individual, a community, or a population may have that can affect ADLs and IADLs.
3. Describe a client-centered approach to evaluation, and explain why it is an important consideration in ADL and IADL training.
4. Explain the usual procedures for ADL and IADL assessments.
5. Explain how to record levels of independence and summarize the results of an ADL/IADL evaluation.
6. Explain the purpose of performing a home evaluation and when it may be indicated.
7. Give at least five examples of client factors that may have limitations that can impact performance in occupations and how each can affect an ADL and IADL (e.g., if someone has shoulder range of motion limitations, he or she may have difficulty donning a shirt (ADL) and reaching for object on a shelf when cooking a meal (IADL)).
8. Give examples of how difficulties in performance skills (motor and praxis skills, sensory-perceptual skills, emotional regulation skills, cognitive skills, communication and social skills) can affect specific ADL and IADL abilities.
9. Discuss considerations for selecting adaptive equipment for performance of ADLs and IADLs. Describe at least five pieces of adaptive equipment that may be used to increase independence and the conditions for which it may be indicated.
10. Describe, perform, and teach specific ADL techniques for individuals with limited range of motion (ROM) and strength, incoordination, paraplegia, tetraplegia, low vision, and for the exceptionally large client.

Threaded Case Study | Anna, Part 1

Anna is a 29-year-old woman who was diagnosed with a T4 spinal cord injury (SCI) from a car accident. She has complete sensory and motor loss below the level of injury. She is currently in an inpatient rehabilitation program. Prior to her injury, Anna lived in a recently purchased house with two bedrooms and one bathroom with her husband and 2-year-old daughter. In addition to caring for her daughter, Anna spent much of her time performing household chores such as cooking, doing laundry, and grocery shopping. Anna also took care of her family's finances and enjoyed being in a Bible study with her friends. Anna dropped their daughter off at a daycare center while she worked part-time as a bookkeeper at her church. Her husband picked up their daughter after spending a full day at his job as an auto mechanic. The family depended on Anna's part-time income to pay for some of the bills. Anna's mother, Martha, has been caring for her granddaughter since Anna's accident. Martha agreed to temporarily live with Anna and her husband and granddaughter after Anna's discharge home until Anna can independently take care of her child.

Anna currently requires minimal assistance with basic transfers, bed mobility, and lower body dressing because of decreased endurance, pain in her back, and decreased trunk control. She requires minimal assistance with verbal cues for proper techniques for weight shifts in her wheelchair and skin checks to ensure skin integrity. Anna reports she has been overwhelmed with all the new things she has had to learn. She requires moderate assistance with bowel and bladder care and showering/bathing tasks. She is independent with wheelchair mobility on indoor flat surfaces but requires standby assistance to propel in tight areas and corners and while

propelling up ramps because of fatigue, decreased trunk control, and reduced upper body strength. She is independent with seated-level activities such as hygiene and grooming at the sink and light kitchen tasks in the rehabilitation unit's kitchen.

Anna and her husband are concerned about the amount of assistance she may require when Anna is discharged from the rehabilitation program. Their home is also not wheelchair accessible at this time. Though they appreciate Martha and her offer to live with them after Anna's discharge home from the hospital, they have concerns about Anna's father living alone because he is quite dependent on his wife for meals and taking care of household tasks.

Anna wants to be as independent as possible in her basic self-care and wants to be able to take care of her home and her daughter. She would also like to eventually return to work and resume driving. She wants to return to her Bible study and church soon to thank all the people who have supported her through this time. She also knows at some point she should resume her part-time job to contribute to the household finances.

Critical Thinking Questions

1. What ADL and IADL tasks will Anna need to master in order to be more independent and to return home safely with her family?
2. What is the role of occupational therapy in helping Anna to return home safely and to eventually reach her goals of independence?
3. With all the occupational performance areas that need to be addressed, how can an occupational therapist prioritize which areas to address?

The American Occupation Therapy Association (AOTA), the U.S. national professional organization of occupational therapy practitioners, recognizes the Occupational Therapy Practice Framework: Domain and Process, Second Edition (OTPF-2),³ an official document intended for internal and external audiences.³ This chapter describes both the aspects of the domain and process of occupational therapy (OT) in regard to activities of daily living (ADLs) and instrumental activities of daily living (IADLs) as well as focuses on specific intervention strategies for assisting clients to optimize occupational functioning.

According to the OTPF, ADLs and IADLs are considered two of eight broad categories of “areas of occupation” in which clients engage.³ ADLs and IADLs include, but are not limited to, routine tasks of personal care, functional mobility, communication, home management, and community mobility.^{3,12} Evaluation and training in the performance of these important life tasks have long been important aspects of OT programs in virtually every type of health and wellness practice area. Loss of ability to care for personal needs and to manage the environment can result in loss of self-esteem and a deep sense of dependence. Family roles are also disrupted, as partners are frequently required to assume the function of caregiver when one loses the ability to perform ADLs or IADLs independently.

In the broadest sense, service delivery in the areas of occupation begins with the OT receiving a referral for service, performing an evaluation, then forming an intervention plan and assessing the outcome of the process. The OT practitioner and client collaborate to identify which areas of occupation, such as ADLs and IADLs, the client wants or needs to participate in to optimize health and wellness. The need to learn new methods, use assistive devices to perform daily tasks, or modify the environment may be temporary or permanent, depending on the particular dysfunction, the environment, the prognosis for recovery, and a multitude of other factors.

Definitions of ADLs and IADLs

Daily living activities can be separated into two areas: activities of daily living (ADLs) (also called personal activities of daily living [PADLs] and basic activities of daily living [BADLs]) and instrumental activities of daily living (IADLs). ADLs require basic skills and focus on activities to take care of one’s own body. ADLs include self-care tasks such as bathing/showering, bowel and bladder management, dressing/undressing, eating (or swallowing), feeding, functional mobility such as transfers and bed mobility, sexual activity, toilet hygiene, and the care of personal devices such as hearing aids, orthotics, and splints.¹

IADLs require more advanced level skills in all performance areas. IADLs generally require use of executive functions, social skills, and more complex environmental interactions than ADLs. IADL tasks include care of others and of pets; child rearing; communication management

■ Box 10-1

ADL and IADL Categories

Activities of daily living (ADLs)
 Functional mobility
 Self-feeding
 Eating (swallowing)
 Dressing
 Personal hygiene and grooming
 Bathing and showering
 Bowel and bladder management/toilet hygiene
 Sexual activity
 Sleep/rest
 Personal device care
 Instrumental activities of daily living (IADLs)
 Care of others/pets/child rearing
 Communication management
 Community mobility
 Financial management
 Health management and maintenance
 Religious observance
 Safety and emergency maintenance
 Shopping
 Home establishment and management
 Meal preparation and cleanup

such as use of telephones; use of personal digital assistants and computers; community mobility such as driving and use of public transportation; and financial management, such as use of cash and check writing, most of which Anna reported as areas to be addressed. Other IADLs include the category health management and maintenance, such as Anna performing regular weight shifts while up in the wheelchair and remembering her therapy appointments. Home establishment and management, a category that includes housecleaning and meal preparation and cleanup, are two other IADLs that Anna was responsible for completing in her home. Religious observance occupations (such as Anna’s ability to participate in her Bible study), safety and emergency maintenance (such as Anna’s ability to appropriately notify authorities in case of emergencies), and shopping are other important IADLs (Box 10-1).

Considerations in ADL and IADL Occupational Analysis and Training

The overall goal of any ADL and IADL training program is for the client and family to learn to adapt to the life changes or situations and to participate as fully as possible in those occupations that are meaningful. The following are important considerations when analyzing ADLs/IADLs. A comprehensive evaluation includes assessing client factors, performance skills, performance patterns, the physical and social environment, and the client’s contextual framework. Each of these areas is defined here in relationship to an ADL/IADL evaluation and intervention plan.

Definition of “Client”

According to the OTPF-2,³ the term *clients* refers to persons, organizations, and populations who receive occupational therapy services. Persons include the actual person receiving services, such as Anna, her husband, her family, and her employers and other significant relations. Organizations refer to businesses, industries, or agencies, such as Anna’s church, which may receive general consultation or referral by an occupational therapist on accessibility. Populations refer to larger people groups in communities such as refugees and survivors of particular natural or manmade disasters. Most of the intervention strategies in this chapter will relate to providing such intervention to persons or individuals as clients—such as Anna—though it is acknowledged that occupational therapists also provide services to organizations and populations in the area of ADLs and IADLs.

Client Factors

The analysis of occupational performance in ADLs and IADLs includes observing the client’s performance and noting skills and patterns and the factors that support them.¹ Client factors are specific abilities, characteristics, or beliefs including strength, range of motion (ROM), coordination, sensation, a belief that one has potential to improve, and balance. These client factors are important to consider for Anna’s functioning. Is her ROM and strength intact in her upper body? How is her trunk control and balance?

Client factors can be assessed to determine the potential for remediation and restoration or possible need for adaptive equipment or other modifications. In Anna’s case, it would be important to know whether the spinal cord injury is complete and whether she has potential for muscle return to determine an appropriate approach to treatment. Other client factors include cognitive functions such as memory, attention, and problem solving. These are assessed in relation to ADLs and IADLs. Emotional functioning for coping strategies and behavior management also need to be considered when assessing and treating ADLs and IADLs.¹ The OT questions, “Is Anna requiring cues to perform her weight shifts and skin checks because she has a memory deficit? Or is she having difficulties learning new techniques and strategies because of issues surrounding coping with the disability?”¹ How is her sleep quality? Sleep deficits can severely hamper performance in terms of memory and attention (see [Chapter 13](#)). Specific assessments to identify and measure activity demands and client factors contribute information influencing ADL and IADL performance.

Performance Skills

The OTPF describes performance skills as “abilities clients demonstrate in the actions they perform” (p. 639)³ and include motor/praxis skills, sensory/perceptual skills, emotional regulation skills, cognitive skills, communication, and social skills. Whereas client factors reside within a person, performance skills are those that are observable and

demonstrable. Examples of a motor/praxis skill for IADLs may be Anna’s ability to reach and bend down to retrieve a pot from a low cupboard or maintain balance while performing the ADL of transferring to a low soft surface. A client with difficulty in sensory/perceptual skills may have difficulty with the ADL of dressing to properly orient his T-shirt. A client with difficulty with the cognitive skill of sequencing the steps of a task may have difficulty taking a shower. Should he turn on the water first or transfer into the shower first? Should he start drying himself off first or rinse the soap off first?

Performance Patterns

Habits, routines, roles, and rituals are all performance patterns according to the OTPF-2.³ All can be helpful or detrimental to occupational performance. As cited in the OTPF-2 (p. 641),³ habits are “specific, automatic behaviors that can be useful, dominating, or impoverished.”^{13,32} An example of an ADL habit may be automatically placing a napkin on one’s lap before starting to eat or placing the right leg into pant legs first, then the left leg. Routines are “established sequences of occupations or activities that provide a structure for daily life” (p. 641).³ An example of a routine ADL may be Anna’s routine of waking up at the same time every day and completing the sequence of toileting, showering, dressing, hygiene and grooming, and eating breakfast on a regular basis. Anna’s IADL routine may have been to help her daughter to get ready for the day by completing such activities as changing her diaper, getting her dressed and cleaned, making her breakfast, packing her lunch, and driving her to daycare. Roles are “expected by society, shaped by culture, and may be further conceptualized and defined by the client” (p. 641).³ Examples of roles might include a husband of a wife with severe rheumatoid arthritis or a college student who lives independently in an apartment with a roommate. Important roles for Anna are those of wife, mother, daughter, worker, and Bible study member. Rituals are “symbolic actions with spiritual, cultural, or social meaning that contribute to the client’s identity and reinforce the client’s values and beliefs.”¹⁷ Examples of rituals that are in the realm of ADLs and IADLs include praying or saying grace before every meal or celebrating particular holidays with foods that are only served on that date and have special cultural meanings. Understanding performance patterns including habits, routines, roles, and rituals will allow the OT practitioner to identify performance deficits, set priorities with goal setting, and help the client reestablish continuity in daily living. For example, with her new functional status, Anna may not be able to perform all of the previous morning IADL routines with her daughter. She may have to establish new routines with her daughter and learn to perform those activities differently. Or others, at least in the early stages, may have to assume responsibility for those tasks. Anna may need to redefine her role in the family, an important undertaking for an occupational therapist to help facilitate.

Environment

The environment to which the client will be discharged after treatment is an important consideration. The OTPF-2 describes the environment as the “external physical and social environments that surround the client and in which the client’s daily life occupations occur” (p. 642).³ A physical environment includes the natural and the built environment and the objects in them. A few of the external environments for Anna are her home and the contents in it, her place of work, and her church. The social environment includes relationships by persons, groups, and organizations. Anna’s social environment includes her husband, daughter, parents, coworkers, and friends. Given Anna’s circumstances, questions abound such as who will be her primary caregiver when she goes home, her mother or her husband? How long will Anna’s mother live with her family? Will Anna plan to return to work and community activities? Does Anna’s family own or rent their home? Will Anna be alone at home at times? How important are her friendships to her for social support? The answers to the questions about the physical and social environment will strongly influence the treatment priorities.

Cultural, Personal, Temporal, and Virtual Contexts

The terms *context* and *environment* have been used interchangeably in the literature but are defined separately in the OTPF-2, though they are considered to be interrelated.³ Context can refer to situations or conditions within and around the client. The OTPF-2 describes context as cultural, personal, temporal, and virtual.

A cultural context includes “customs, beliefs, activity patterns, behavior standards, and expectations accepted by the society” in which one is a member (p. 642).³ Cultures can differ vastly in terms of ADLs/IADLs. For example, one culture may view bathing as a private event, whereas another may consider it a communal event.

Cultural context is also important to consider in understanding differences in how independence is defined and valued. The AOTA Position Paper on the construct of independence supports the view that independence is “defined by the individual’s culture, values, support systems, and ability to direct his or her life.”²³ A thorough evaluation will allow the OT practitioner to understand what activities are critical to each client in order to reestablish the client’s sense of directing his or her own life. An example of differing cultural values frequently occurs when an occupational therapist raised in a more Westernized culture considers it important to foster independence in ADLs and IADLs but a client from a different cultural view may not see independence in ADL tasks as highly valued. The OT practitioner may unfairly label the client as unmotivated. For the individual whose culture does not value ADL or IADL independence, the occupational therapist may focus primarily on teaching the client and family to adapt. The focus would be on family training and

identifying the activities of highest value to the client and family.

The ultimate goal of any ADL and IADL training program is for the client and family to learn to adapt to the life changes that necessitated a referral to the occupational therapist. For the individual who values independence, the goal may be to achieve the maximal level of independence. It is important to note that this level is different for each client. For the client with mild muscle weakness in one arm, complete independence in ADLs may be the maximum. In contrast, for the individual with a high-level quadriplegia, self-feeding, oral hygiene, and communication activities with devices and assistance may be the maximal level of independence that can be expected. The potential for independence depends on each client’s unique personal needs, values, capabilities, limitations, and social and environmental resources.

Personal context includes a person’s demographic features, such as age, gender, and educational level, which also need to be considered in ADLs and IADLs. The ADL/IADL tasks and routines may differ based on any one of many demographic factors. For example, a young adult female may consider it important to regain the ability to shave her legs, whereas an elderly female may not. Temporal context includes contexts that refer to time, such as time of year, time of day, or stages of life. An example of how temporal context can be important in ADLs is determining when certain tasks, such as dressing and eating a meal, occur during the day. Virtual context refers to interactions in “simulated, real-time, or near-time situations, absent of physical contact” (p. 646).¹ An example of virtual context for Anna is her ability to contact friends using her computer or cell phone. It would be important for an occupational therapist to recognize the significance of this virtual context in order for Anna to be connected socially and otherwise.

Finances

Financial resources available for potential expenses such as assistant care, special equipment, and home modifications are other important considerations for ADL and IADL performance. For example, consider a client who is a new full-time wheelchair user and can no longer stand to take showers, requiring significant assistance of a caregiver to perform the task. If the client has unlimited financial resources, owns his own home, has an able-bodied committed caregiver, a desire to take showers daily, and an eagerness to fully remodel his home for accessibility, an OT may recommend a fully remodeled bathroom by a licensed contractor. Anna has fewer financial resources but has reliable caregivers and owns her home. She also desires to shower regularly but an occupational therapist may make recommendations for less costly modifications such as removing the sliding glass door from the bathtub/shower and a replacing it with a shower curtain or obtaining a bath bench and other equipment.

Occupational Justice

As cited in the OTPF-2,³ the term *occupational justice* was coined by Townsend in 2003 to describe the occupational therapy profession's concerns with the ability of all people to be given the opportunity to engage in occupations, including the ADLs and IADLs that are important to them. Many times occupational therapists are the first to recognize the disparity in abilities to meet occupational needs because of social, economic, and other factors. Occupational therapists can assist in supporting social policies, actions, and laws that allow all persons to engage in occupations that are important to them.³ An example of applying this principle of occupational justice to the most basic of ADLs involves Anna's roommate in the inpatient rehabilitation unit who does not have the resources to bring in clothes to practice dressing skills. The only clothes Anna's roommate had were destroyed in the accident that brought her into the hospital. Anna's roommate has only her hospital-issued gown and pants to practice dressing skills. On a small scale the OT can help to equalize this disparity by working with social services to allow Anna's roommate access to clothes she can use in order to increase her independence in this important ADL. A common situation for an OT is one where a piece of adaptive equipment such as a transfer bath bench is neither covered by insurance nor within the client's ability to purchase. Creative, compassionate, and resourceful OTs can help to bridge this disparity to help all clients to perform ADLs and IADLs that are important to them.

Evaluation of Areas of Occupation

According to the OTPF-2, occupational therapy's overarching goal for both the domain and the process is "supporting health and participation in life through engagement in occupation."³ A comprehensive evaluation of occupational performance involves collaborating with the client to determine what he or she wants and needs to do to support to health and participation.³ According to the OTPF-2, areas of occupation include ADLs, IADLs, rest and sleep, education, work, play, leisure, and social participation.

The process of how occupational therapy services are delivered to a client as outlined by the OTPF-2 is via evaluation, intervention, and outcomes. The "client" in this process may be defined as a person, those in an organization, or those in a population (community). The process may seem linear but is actually dynamic, allowing the OT practitioner to continually assess the process toward reaching goals.³

In a client-centered approach, the therapist collaborates with the client or the family/caregivers, centering the occupational therapy process on the client's priorities and fostering an active participation toward the outcome. Evaluation consists of creating an occupational profile and a performance analysis of skills and patterns and the factors that influence performance. An occupational profile describes the client's occupational history, patterns of daily living, interests, values, and needs.³

ADL and IADL Performance

An occupational performance analysis of ADLs and IADLs may include using a checklist as a guide for questioning and the selection of specific activities to perform as identified during the interview for the occupational profile. For example, in Anna's case the occupational therapist may select to have Anna perform lower-extremity dressing and transfer to the commode as two key activities. The OT can then determine strategies to promote independence and provide caregiver instruction regarding how to provide Anna with the appropriate level of assistance.

Many types of ADL and IADL checklists and standardized tests are available. They all cover similar categories and performance tasks.⁷ The use of a standardized test will ensure a more objective assessment and provide a standard means of measurement. A standardized assessment tool can be used at a later time for reevaluation, and some assessments allow for comparison to a norm group. Both Asher⁷ and Law²⁶ have developed resources on assessments that can be used as a resource for selecting appropriate tools for evaluation. The occupational therapist should review the literature periodically to learn about new assessments developed by occupational therapists and about those that have been developed as interdisciplinary assessments, such as the Assessment of Motor and Process Skills¹⁸ and the Functional Independence Measure (FIM).^{26,40}

General Procedure

When data have been gathered about the client's physical, psychosocial, and environmental resources, the feasibility of ADL assessment or ADL training should be determined by the occupational therapist in concert with the client, supervising physician, and other members of the rehabilitation team. In some instances, ADL training should be delayed because of the client's limitations or in favor of more immediate intervention objectives that require the client's energy and participation.

The interview may serve as a screening device to help determine the need for further assessment by observation of performance. This need is determined by the therapist based on knowledge of the client, the dysfunction, and previous assessments. A partial or complete performance analysis is invaluable in assessing ADL performance. The interview alone can lead to inaccurate assumptions. The client may recall performance before the onset of the dysfunction, may have some confusion or memory loss, and may overestimate or underestimate his or her abilities because there has been little opportunity to perform routine ADLs since the onset of the physical dysfunction.

Ideally, the occupational therapist assesses the performance of activities in the environment and context where they usually take place.⁵ For example, a dressing assessment could be arranged early in the morning in the treatment facility, when the client is dressed by nursing personnel, or in the client's home. A self-feeding assessment should occur at regular meal hours. If this timing is not possible, the assessment may be conducted during regular treatment

sessions in the OT clinic under simulated conditions. Requiring the client to perform routine self-maintenance tasks at irregular times in an artificial environment may contribute to a lack of carryover, especially for clients who have difficulty generalizing learning.

The therapist should select relatively simple and safe tasks from the ADL and IADL checklist and should progress to more difficult and complex items, including some that involve safety measures. For example, with Anna, transfer training would likely start with transfers from her wheelchair to her bed and then progress to commode transfers, which are more difficult. The ADL assessment should not be completed at one time because this approach would cause fatigue and create an artificial situation. Tasks that would be unsafe or that obviously cannot be performed should be omitted and the appropriate notation made on the assessment form.

During the performance analysis, the therapist should observe the methods the client is using or attempting to use to accomplish the task and try to determine causes of performance problems. Common causes include weakness, spasticity, involuntary motion, perceptual deficits, cognitive deficits, and low endurance. If problems and their causes can be identified, the therapist has a good foundation for establishing training objectives, priorities, methods, and the need for assistive devices.

Other important aspects of this analysis that should not be overlooked are the client's need for respect and privacy and the ongoing interaction between the client and the therapist. The client's feelings about having his or her body viewed and touched should be respected. Privacy should be maintained for toileting, grooming, bathing, and dressing tasks. The therapist with whom the client is most familiar and comfortable may be the appropriate person to conduct ADL assessment and training. As the therapist interacts with the client during the performance of daily living tasks, it may be possible to elicit the client's attitudes and feelings about the particular tasks, priorities in training, dependence and independence, and cultural, family, and personal values and customs regarding performance of ADLs.

Recording Results of ADL Assessment

During the interview and performance analysis, the therapist makes appropriate notations on the checklists. If a standardized assessment is used, the standard terminology identified for that assessment is used to describe or measure performance. Nonstandardized tests may include separate checklists for self-care, home management, mobility, and home environment assessments. When describing levels of independence, occupational therapists often use terms like *maximum*, *moderate*, and *minimal assistance*. These quantitative terms have little meaning to healthcare professionals unless they are defined or unless supporting statements are included in progress summaries to give specific meanings for each. It also should be specified whether the level of independence refers to a single activity, a category of activities such as dressing, or all ADLs. In designating levels of

independence, an agreed-upon performance scale should be used to mark the ADL checklist. The following general categories and their definitions are suggested:

1. *Independent*. Client can independently perform the activity without cuing, supervision, or assistance, with or without assistive devices, at normal or near normal speeds. Task is completed safely. If the client requires assistive devices or performs the activity at a slower than customary speed, the term *modified independence* may be used.
2. *Supervised*. Client requires general supervision (not hands-on) and may require a verbal cue for safety. The OT feels comfortable being greater than arm's length away at all times.
3. *Standby assistance (SBA)/contact guard assistance (CGA)*. Client requires caregiver or someone to provide hands-on guarding to perform a task safely. Note: OTs may tend to use the term *SBA*, whereas other disciplines may use *CGA*.
4. *Minimal assistance*. Client requires 25% physical or verbal assistance of one person to complete a task safely. (Client performs 75% or more of the task.)
5. *Moderate assistance*. Client requires 50% physical or verbal assistance of one person to complete a task safely. (Client performs 50% to 74% of the task.)
6. *Maximal assistance*. Client requires physical or verbal assistance for 51% to 75% of an activity by one person. (Client performs 25% to 49% of the task.) The helper is doing more than half the work or task, while client is performing less than half.
7. *Dependent*. Client requires more than 75% physical or verbal assistance. Client does less than 25% of the task. For example, she or he can perform only one or two steps of the activity or very few steps of the activity.

These definitions are broad and general. They can be modified to suit the approach of the particular treatment facility.

As stated previously, the AOTA²³ published a position paper on a definition of *independence* that differs from the relatively narrow definition noted earlier. Hinojosa²³ stated: "Independence is a self-directed state of being characterized by an individual's ability to participate in necessary and preferred occupations in a satisfying manner, *irrespective of the amount or kind of external assistance desired or required*" (p. 660). This means that an individual's independence is not related to whether an individual performs the activity or not or in a modified fashion or with assistance.

Information from the ADL assessment is summarized succinctly for inclusion in the client's permanent record so that interested professional coworkers can refer to it. A sample case study (Mrs. Hayes) with resulting ADL evaluation summaries of an initial assessment and progress report are included in Figure 10-1, A. Two evaluation forms are being included to show Mrs. Hayes's progress, a detailed ADL checklist (see Figure 10-1, A), and an abbreviated

Text continued on p. 173

OCCUPATIONAL THERAPY DEPARTMENT
Activities of Daily Living Evaluation/Progress Form

Name: Mrs. Hayes Age: 72 Onset Date: 2/3 Today's Date: 4/3
 Medical Diagnosis: Lt. CVA Treatment Diagnosis: dysphagia, mild right hemiparesis; ↓'d independence ADL/IADL
 Past Medical History: Unremarkable per pt. report and chart
 Precautions: Soft foods, thick liquids
 Mode of Ambulation: Mod A 20' with FWW, primarily uses w/c Hand Dominance: Right
 Social / Home environment: Married 45 years, was primary caregiver to husband, lives in one-story house which they own; four adult children live out of area; has 24 hour caregivers to assist in home since CVA
 Occupational Profile/Previous Level of Function: Prior to the CVA, pt. was I with ADL, IADL, volunteering at thrift store, going for walks with friends, paying bills, driving and caring for husband who has ↓'d vision and diabetes but who is otherwise ambulatory and cognitively intact. Pt. was a homemaker while she raised her four children and highly values her independence, community involvement and volunteering. Pt. enjoyed spending time with friends, potted gardening and entertaining her family including many grandchildren when they visit from out of town. Her goals are to be as independent as possible in her ADL/IADL, to be able to help her husband and to be able to enjoy previous leisure activities.

ADL checklist (Figure 10-1, B). The detailed form with Mrs. Hayes’s information incorporated into it will help the novice OT practitioner appreciate the details of many ADLs and IADLs that may be taken for granted by an able-bodied individual. The abbreviated form is more likely to be used in actual practice. A third form, also included, is a home management checklist (Figure 10-2). When reviewing these, the reader should keep in mind that the assessment and progress summaries relate only to the ADL and IADL portions of the intervention program.

Instrumental Activities of Daily Living

Home Management Assessment

Home management tasks are assessed similarly to self-care tasks. First, the client should be interviewed to elicit a description of the home and of former and present home management responsibilities and the significance of the role. Tasks the client needs to perform when returning home, as well as those that he or she would like to perform, should be determined during the interview. If the client has a communication disorder or a cognitive deficit, aid from friends or family members may be enlisted to get the information needed. The client may also be questioned about his or her ability to perform each task on the activities list. The assessment is much more meaningful and accurate if the interview is followed by a performance assessment in the ADL kitchen or apartment of the treatment facility or, if possible, in the client’s home. An example of a standardized assessment to evaluate the executive skills required to perform IADLs is the Executive Function Performance Test.⁸ Examples of specific IADL tasks to evaluate for home

management can be found in the home management checklist (see Figure 10-2).

The therapist should select tasks and exercise safety precautions consistent with the client’s capabilities and limitations. The initial tasks should be simple one- or two-step procedures that are not hazardous, such as wiping a dish, sponging a tabletop, and turning the water on and off. As the assessment progresses, tasks graded in complexity and involving safety precautions should be performed, such as making a sandwich and a cup of coffee and vacuuming the carpet. For example, with Anna, initial tasks may include making a sandwich and using the microwave, as using a manual wheelchair in her own home is new for her and requires working from a seated versus a standing position. As Anna performs these simple tasks using her wheelchair, the OT will be able to observe and make suggestions about modification to her kitchen, reorganization, safety techniques, or methods to transport items and simplify tasks.

Home management skills apply to women, men, and sometimes adolescents and children. Individuals may live independently or share home management responsibilities with their partners. In some homes, it is necessary for a role reversal to occur after the onset of a physical disability, and the partner who usually stays at home may seek employment outside the home, whereas the individual with a disability remains at home. In Anna’s case, she has stated she would like to participate in previous home management activities and eventually return to work. Anna’s occupational therapist will collaborate with her on home tasks to be completed by her so that interventions can be prioritized. Until Anna can perform the tasks more independently,

Suggestions for home modification: _____

FIGURE 10-2, cont'd

Anna's mother or husband may be available to perform some of these tasks with direction from Anna.

If a client will be home alone, several basic ADL and IADL skills are needed for safety and independence. The most basic IADL skills required to stay at home alone include the ability to³ prepare or retrieve a simple meal,^{1a} employ safety precautions and exhibit good judgment,³ take medication, get emergency aid⁶ if needed, have a system for managing toileting, and have a method to allow for rest periods. The occupational therapist can assess the potential for remaining at home alone through the activities of home management assessment. An evaluation such as the Executive Function Performance Test can be used to assist in determining whether a person is safe to remain at home or how much assistance is required for some IADL tasks.⁸ A child with a permanent disability also needs to be considered for assessment and training for IADL skills as he or she develops and matures with a growing need for independence.

Home Assessment

To help with the transition from a treatment facility to home, a home evaluation may be performed. A home evaluation can serve several functions, including assessing a home for safety and accessibility, offering a way for an OT to assess client functioning at home, and determining a time when caregiver training can occur. From the initial meeting with a client or caregivers, the occupational therapist must have an idea about the home environment to which the client will return. For example, the OT treating Anna or Mrs. Hayes should know from early on whether they live in second story apartment without an elevator or in a one-story house. When discharge from the treatment facility is imminent, a home assessment may be carried out to facilitate the client's maximal independence in the living environment.

As will be described here, not all clients who are seen by an occupational therapist in a facility will need or receive a home evaluation. The home assessment will provide the

Case Study | Mrs. Hayes

Mrs. Hayes is a 72-year-old woman who incurred a cerebral thrombosis resulting in a left cerebrovascular accident (CVA) 2 months ago. She lives in a modest home with her husband of 45 years. Mrs. Hayes was active before her CVA, volunteering 10 hours a week at a local charity thrift store with her friends and caring for her husband who has diabetes and poor vision. Outside of needing help with his medications and with cooking, her husband is ambulatory, cognitively intact, and independent with ADLs. She was independent with all of the indoor home management activities and paid the bills for herself and her husband. She and her husband have a gardener, but Mrs. Hayes enjoyed gardening with potted plants.

Following her CVA, Mrs. Hayes spent 3 weeks in acute rehabilitation. Before Mrs. Hayes was discharged from the acute rehabilitation facility, the OT performed a home evaluation. (See the “Home Assessment” section that follows.) Following through with the OT’s recommendations, the client’s family made simple home modifications to increase safety and independence in the home.

The CVA resulted in an ataxic gait, mild dysarthria (slurred speech), dysphagia (swallowing deficit), and mild right hemiparesis (weakness). She was referred to outpatient OT for evaluation and training in ADLs and IADLs and for treatment of dysphagia.

The initial evaluation process involved an interview with the client and her husband to create an occupational profile. Mrs. Hayes expressed concern about how she and her husband will manage, as her four adult children live five hours away. Her children have hired caregivers through an agency who are with the couple in shifts for 24 hours a day. Mrs. Hayes and her husband are anxious to be on their own again and do not want to be a financial burden on their children. Based on the priorities and problems identified by the client and her husband, the occupational performance analysis included the use of the Executive Function Performance Test (EFPT)⁹ and an ADL performance evaluation. The initial performance evaluation was completed during the first 1-hour session, whereas the EFPT was completed on the second visit.

During the initial evaluation, Mrs. Hayes became restless after 15 minutes, but with minimal redirection she continued to attend to the tasks. She also demonstrated decreased frustration tolerance during the assessment and required minimal encouragement to continue with fine motor tasks, which were difficult for her. Mrs. Hayes is independent with eating (as long as she is in compliance with soft diet for swallowing problems), hygiene, and grooming while seated and with toileting tasks. Mrs. Hayes requires supervision with transfers from her wheelchair to the bed and the toilet but requires minimal assistance to transfer onto the bath bench because of occasional loss of balance, setup, and cues for safety. She requires minimal assistance with upper-body dressing and bathing and moderate assistance for lower-body dressing. She has difficulty with handwriting, use of the telephone, and handling keys. She requires moderate assistance to walk 20 feet using a front-wheeled walker (FWW) but is independent with manual wheelchair mobility on indoor flat surfaces. Her visual fields are intact and she has no

visual-spatial deficit. Her left upper-extremity (UE) strength and active range of motion (AROM) are within normal limits (WNL). Her right UE strength is WNL proximally, but testing by use of a dynamometer demonstrates mild weakness in her hand. Right UE AROM is WNL. Her muscle tone in her bilateral UEs is WNL. Her right hand coordination is mildly impaired, as demonstrated with moderate difficulty pushing buttons on the phone and tying her shoes. She is able to stand while holding on to a stable surface but cannot use her hands for a task while standing because of mild balance impairments.

Results of the EFPT demonstrated significant deficits in organization of cooking and bill-paying tasks requiring moderate assistance to complete both. The EFPT results indicated that Mrs. Hayes required minimal assistance with medication management and phone management.

A swallow assessment demonstrated moderately impaired tongue coordination and minimal delay with a swallow. Mrs. Hayes has already modified her diet by selecting very soft foods and slightly thickened liquids.

Mrs. Hayes tolerated the full occupational therapy evaluation but reported, “I’m tired” at the end of the session. She reported that her endurance is diminished since the CVA, especially toward the end of the day. She admitted that in the later afternoon hours, “I have hard time remembering things and concentrating.” When queried about her sleep, Mrs. Hayes reports she has difficulty falling asleep and that she wakes up in the middle of the night and cannot fall back asleep because of “too much on my mind” and discomfort in her legs. She reports having sleep difficulties prior to the CVA. Mrs. Hayes is highly motivated and has the potential to prepare simple hot meals and perform basic self-care independently, except for showering, for which she may require supervision. Mrs. Hayes would like to be as independent as possible in her ADLs and IADLs and would like to resume caring for her husband. She acknowledges that her right hand has gotten stronger, but she reports frustration that it is taking longer than she expected. She would like to eventually resume her leisure activities.

Progress Report

Mrs. Hayes has attended OT two times a week for 6 weeks. She is generally cooperative and motivated, although periodically she becomes discouraged as she continues to have an ataxic gait and requires the use of the manual wheelchair for independent mobility. Treatment has focused on lower-extremity (LE) dressing, tub transfers, oral-motor exercises to improve swallowing, instruction in sleep hygiene techniques, and simple meal preparation. Because the caregiver drives Mrs. Hayes and her husband to the OT appointments, the OT has also trained the caregiver in how to assist the client to be more independent in her ADLs.

Mrs. Hayes has made significant progress in the treatment program. She has progressed from requiring moderate assistance with lower-extremity dressing to being independent while seated. She has improved from chair-level grooming to standing with one-hand stabilization while using the other to brush her hair and teeth. Progress has been made from

requiring minimal assistance with bathing to requiring supervision only with bathing on a shower bench. Initially requiring supervision with bed to wheelchair transfers, she is now independent. From requiring minimal assistance with transfers onto the shower bench, she now requires supervision, mainly for setup of the environment. From moderate difficulty with use of the phone, she has progressed to using the phone independently; from requiring moderate assistance with bill-paying activities and medication management, she has progressed to the supervised level. From being dependent with oral-motor exercises, she has progressed to supervised. Mrs. Hayes is now independent in cold meal preparation after initially requiring moderate assistance. Mrs. Hayes has expressed some improvement in her sleep at night and reports following through with two sleep hygiene strategies but that she still has difficulties and does not wake up refreshed.

Mrs. Hayes continues to require a soft diet and slightly thickened liquids because of swallowing difficulties. She consistently follows through with the use of safety techniques for swallowing and is safe and independent to do so. She continues to have impaired hand function but is learning compensatory techniques to adapt her method of performing various ADLs. She is also strengthening her right hand with exercises provided by the occupational therapist to restore as much function as possible to that hand.

The occupational therapist has coordinated treatment and goals with the physical therapist and social worker. The therapist has recommended that the social worker refer the client's husband to a low-vision center for evaluation, as he was dependent on his wife and never received instruction in

low-vision training. His independence will relieve some of Mrs. Hayes's burden of care giving. Mrs. Hayes has also been referred to the National Sleep Foundation for more information and to her primary physician who referred her to a physician specializing in sleep medicine. The sleep specialist evaluated Mrs. Hayes and scheduled her for an overnight sleep study in 4 weeks. See Chapter 13 for more information on the occupation of sleep and rest.

Mrs. Hayes and her husband are pleased with her increased independence. With input provided by the occupational therapist, the family will decrease the hours needed for a hired caregiver to 16 hours. For 8 hours a day during the day the hired caregiver will assist Mrs. Hayes with bathing, meals, driving to appointments, shopping, and housekeeping. Occupational therapy will now focus on hot meal preparation, bed making, and exploring leisure interests, along with continuing to work toward improvement of oral-motor and hand function and improving sleep hygiene techniques.^{8,9,24}

Critical Thinking Questions

1. What deficits is Mrs. Hayes experiencing, and what compensatory strategies can she be taught to improve her ADLs and IADLs?
2. What role does the occupational therapist have in helping Mrs. Hayes to meet her goals for ADLs and IADLs?
3. With all the areas that Mrs. Hayes needs to work on with the occupational therapist, how can the OT prioritize the goals that are most important for Mrs. Hayes to accomplish so that she can continue to live in her home safely with her husband?

family with a list of modifications and durable medical equipment needed to maximize safety and independence in the home and help the therapists understand the physical, cultural, and social environment the client will be returning to so that realistic treatment methods and goals related to mobility, ADLs, and IADLs are established. Insufficient or incorrect information regarding accessibility can lead to costly mistakes in ordering equipment that may lead to impairing the client's safety and potential for greater independence.

The home evaluation should be performed when the client's mobility status is stabilized with status close to where you anticipate it will be at discharge. Collaboration with the physical therapist regarding a client's ambulatory status and potential is essential to determine the timing and necessity of the evaluation. For example, if the physical therapist reports that a client will be primarily walking at discharge, recommendations for home modifications may be very different than if the primary mode of mobility will be a wheelchair.

Ideally, the occupational and physical therapists could perform the home assessment together. During the home visit, the client and essential caregivers/family members or

housemates should be present. However, if it is not feasible to take the client, a wheelchair and other necessary equipment may be taken. Budget, time factors, and reimbursement issues may not allow two professionals to go to the client's home or may prohibit a home visit altogether.

If a home evaluation is not possible prior to discharge, the rehabilitation team along with the client and family members should identify the most serious concerns and develop a plan to address them. Figure 10-3 shows a home safety checklist that can be completed by the client or client's family. Family members or housemates could take pictures and measurements of the home or draw floor plans. Figure 10-4 depicts an occupational therapy home evaluation checklist, which is completed by the OT practitioner.

Much of the information can also be gained by interviewing the client and family member(s) following a trial home visit with the client. The family member or caregiver may be instructed to complete the home visit checklist and provide photographs or sketches of the rooms and their arrangements. Problems encountered by the client during a

Home Safety Checklist

Help prevent falls: Use this list to prioritize work tasks. Leave a copy of this list with the family so they can make further improvements.
Note: 32 inch doorway recommendations are for average size person. If overall width of wheelchair or equipment is greater than 28" need 34 to 36" wide door

1. Exterior entrances and exits

- Increase lighting at entry area
- Install stair rails on both sides
- Install door lever handles; double-bolt lock
- Install bevelled, no step, no trip threshold
- Remove screen or storm door if needed
- Create surface to place packages when opening door
- Install peephole on exterior door at level needed for mobility device
- Repair holes, uneven joints on walkway
- Provide non-slip finish to walkway surface/ramps
- Add ramp
 - Length _____
 - Width _____
 - Rails _____
 - Platform size _____

2. Interior doors, halls, stairs

- Create clear pathways between rooms
- Apply color contrast or texture change at top and bottom stair edges
- Install door lever handle
- Install swing-clear/off set hinges to widen doorway. Minimum width: 32 inches
- Install bevelled thresholds (max ½ inch)
- Replace or add non-slip surface on steps
- Repair or install stair handrails on both sides
- Clear clutter

3. Bathroom

- Install swing-clear/off set hinges to widen doorway. Minimum width: 32 inches
- Install secure wall reinforcement and place grab bars at toilet, bath and shower
- Install adjustable-height shower head
- Install non-slip strips in bath/shower
- Secure floor bathmat with non-slip, double-sided rug tape
- Elevate toilet height by adding portable seat or raising toilet base on a pedestal
- Adapt flush handle or install flush sensor
- Adapt or relocate toilet paper dispenser
- Round counter corners to provide safety
- Insulate hot water pipes if exposed
- Create sitting knee clearance at basin by removing vanity door and shelves underneath
- Install mirror for sitting or standing view
- Install good-quality non-glare lighting
- Install shower with no threshold if bathing abilities are severely limited
- Install bidet

Recommend :

---	--	--

4. Kitchen

- Increase task lighting at sink, stove, etc.
- Install D-type cupboard door handles
- Install adjustable shelving to increase access to upper cabinets
- Increase access to under counter storage space by installing pull-out units
- Insulate hot water pipes if exposed
- Install hot-proof surface near oven
- Install switches and outlets at front of counter
- Install pressure-balanced, temperature-regulated, lever faucets
- Create sitting knee clearance under work sites by removing doors or shelves
- Improve color contrast of cabinet and counters surface edges for those with low vision
- Add tactile and color-contrasted controls for those with low vision
- Move microwave to reachable work surface
- Arrange frequently stored items within easy reach given current mobility device and function

Davies Medical Center; and *Occupational therapy home evaluation form*, Albany, CA, 1993, Alta Bates Hospital.)

5. Living, dining, bedroom

- Widen or clear pathways within each room by rearranging furniture
- Secure area rug edges with double-sided tape
- Remove throw rugs
- Improve access to and from chairs and beds by inserting risers under furniture legs
- Use side bed rail or chairs with armrests
- Install telephone jack near chair or bed
- Enlarge lamp switch or install touch-control lamp at bedside
- Install adjustable closet rods, shelving and light source for better storage access
- Install vertical pole adjacent to chair and sofa
- Raise furniture to appropriate height using leg extender products
- Install uniform level floor surfaces using wood, tile or low-pile rugs

6. Laundry

- Build a counter for sorting and folding clothes
- Adjust clothesline to convenient height
- Relocate laundry appliances
- Use reacher

7. Telephone and door

- Install phone jacks near bed, sofa, and chair
- Install flashing light or sound amplifier to indicate ringing doorbell for those with visual or hearing problems
- Install mailbox at accessible height

8. Storage space

- Install lights inside closet
- Install adjustable closet rods and shelves
- Install bi-fold or pocket doors

9. Windows

- Install handles and locks that are easy to grip, placed at appropriate heights

10. Electrical outlets and controls

- Install light fixtures or outlet for lamps
- Install switches at top and bottom of stairs

11. Heat, air, light, security, water temp, carbon monoxide controls

- Install smoke/CO detectors, fire extinguishers
- Increase residents' access to environmental control systems
- Ensure water temperature is set at safe temperature (120 degrees Fahrenheit, 49 degrees Celsius) to prevent burns (U.S. Consumer Product Safety Commission, Tap water scalds, Document # 5098 retrieved from <http://www.cpsc.gov/cpsc/pub/pubs/5098.html> on August, 26, 2010)

trial home visit should be discussed and the necessary recommendations for their solution made, as described earlier. If a home evaluation is not possible while the client is in the hospital, the home assessment may also be referred to the home health agency that will provide home care services to the client.

The client and a family member should be interviewed prior to the home evaluation to determine the client and family's expectations and the roles the client will assume in the home and community. A culture's or family's values regarding people with disabilities may influence role expectations and whether independence will be encouraged. Willingness and financial ability to make modifications in the home can also be determined. The purposes and procedure of the home assessment should also be clearly explained to the client and caregiver(s) prior to the actual visit.

Understandably, the first time home (which may be at the home evaluation) after an illness or injury can be potentially emotion-filled for everyone concerned, especially for the client. Before performing a home evaluation, especially with the client present, it is important for the occupational therapist to know whether the home being evaluated is new for the client or whether drastic home changes have already had to be made. For example, if Anna lived in a second-story apartment prior to her accident, her family may have had to move to a first-story home. Or if Anna's mother was going to move into her home to help care for her daughter and granddaughter, rooms may have been switched, furniture moved, belongings displaced. Knowing this ahead of time can help the occupational therapist to be ready to provide emotional support to the client as needed.

If the client is present during the home visit, sufficient time should be scheduled so that the client can demonstrate the required functional mobility skills. The occupational therapist may have the client demonstrate selected self-care and home management tasks in the home environment. During the assessment, the client should use the mobility aid and any assistive devices that he or she is accustomed to using. For example, Anna and Mrs. Hayes would be asked to propel their manual wheelchairs throughout the home to determine what access issues they will encounter. The therapist should bring a sturdy tape measure to measure the width of doorways, the height of stairs, the height of the bed, and other dimensions. A digital camera can be useful to record arrangement of furniture, placement of bathroom fixtures, and other architectural structures/possible barriers for later reference when problem solving solutions.

The therapist can proceed to take the required measurements while surveying the general arrangement of rooms, furniture, and appliances. [Figure 10-4](#) provides a format to document critical measurements. It may be helpful to sketch the size and arrangement of rooms for later reference and attach these sketches to the home assessment checklist (see [Figure 10-4](#)). For more information on a variety of checklists, see Letts²⁷ and Anemaet.⁴ Next, the client demonstrates functional mobility skills and essential

self-care and home management tasks. The client's ability to use the entrance to the home and to transfer to and from an automobile, if it is to be used, should be included in the home assessment if time permits.

During the performance assessment, the therapist should observe safety factors, ease of mobility and performance, and limitations imposed by the environment. If the client needs assistance for transfers and other activities, the caregiver should be instructed in the methods that are appropriate. The client may also be instructed in methods to improve maneuverability and simplify the performance of tasks in a small space.

Access into the bathroom and maneuvering with a wheelchair or walker are common problems. Frequently, a bedside commode is recommended until a bathroom can be made accessible or modified to allow independence with toileting ([Figure 10-5](#)). Shower seats can be used in the tub if a client can transfer over the edge of the tub and also may be used in a shower. A transfer tub bench ([Figure 10-6](#)) is recommended for individuals who cannot safely or independently step over the edge of the tub. Installation of a handheld shower hose increases access to the water and also eliminates risky turns and standing while bathing.

The Americans with Disability Act (ADA) Accessibility Guidelines for Buildings and Facilities are available at its website.¹⁵ Not all modifications recommended will necessarily meet the ADA guidelines, as the home will be modified to suit the individual and to compensate for that specific disability. The ADA is meant to apply to public areas and to meet the needs of people with a variety of disabilities. For example, grab bar placement in ADA guidelines indicates a bar should be placed at the back of the toilet. In the case of Mrs. Hayes, who had a stroke, a grab bar placed on both sides of the toilet may be sufficient. Although this recommendation does not meet ADA guidelines, it does allow for safety and independence at the toilet for Mrs. Hayes. A generalist OT practitioner is not expected to know all of the building codes within a city but should have some familiarity with guidelines when making recommendations. The OT should recommend the family only use licensed contractors who are aware of building code requirements in their area. (See [Chapter 15](#) for ADA Guidelines.)

When the home assessment is completed, the therapist should write a report summarizing the information on the form and describe the client's performance in the home. The report should conclude with a summary of the environmental barriers and the functional limitations that the client encountered. Recommendations should include additional safety equipment and assistive devices that are needed. Modification recommendations should include specific details about size, building specifications, costs, and sources. Recommendations may also include further functional goals to improve independence in the individual's home environment. Team members should be notified about the client's performance in the home and accessibility problems so that they can practice skills or be made aware

FIGURE 10-5 Three-in-one commode.
(Courtesy North Coast Medical Inc.)

of issues prior to discharge. For example, the OT may report to the physical therapist that a client such as Mrs. Hayes will eventually need to negotiate a step down into the living room to be more independent. The OT may report to the psychologist that Anna had a difficult time emotionally handling her visit to home in her new functional status.

The therapist should carefully review all recommendations with the client and family. The family should receive a written report with recommendations clearly written. This review should be done with tact and diplomacy in a way that gives the client and family options and the freedom to

decline them or consider alternative possibilities. Family finances may limit the implementation of needed changes. The social worker may be involved in working out funding for needed equipment and alterations, and the client should be made aware of this service when cost is discussed.

The therapist should include recommendations regarding the feasibility of the client's discharge to the home environment or remaining in or managing the home alone, if applicable. If there is a question regarding the client's ability to return home safely and independently, the home assessment summary should include the functional skills the client needs to return home.

FIGURE 10-6 Transfer tub bench.
(Courtesy North Coast Medical Inc.)

Box 10-2

Most Common Modifications Recommended

1. Installation of a ramp or railings at the entrance to the home
2. Removal of scatter rugs, extra furniture, and bric-a-brac
3. Removal of door thresholds (if not level) and the doorjamb
4. Addition of safety grab bars around the toilet and bathtub
5. Rearrangement of furniture to accommodate a wheelchair
6. Rearrangement of kitchen storage
7. Lowering of the clothes rod in the closet

See [Box 10-2](#) for the most common modifications recommended and [Box 10-3](#) for a list of supplies to take on a home evaluation.

Financial Management

If the client is to resume management of money and financial matters independently, a cognitive and perceptual assessment that accurately tests these skills should be implemented. Because some persons with physical disabilities also have concurrent involvement of cognition and perception, the level of impairment should be determined. The OT evaluates the methods and routines the client typically implements for financial management. For example, one client may pay each bill as it arrives by writing a check, whereas another client may pay bills once a month online. The skills needed for each are different and require different

Box 10-3

Supplies to Take on a Home Evaluation

- Measuring tape: Use heavy duty (at least 30 feet long).
 - Clipboard, notepad, laptop
 - Pen
 - Home evaluation checklist
 - Digital camera, video
 - Maps or GPS
 - All important emergency phone numbers (of the nursing station, your supervisor, physician, etc.)
 - Durable medical equipment you think the patient will need (wheelchair, walker, commode, bath bench)
 - Tool kit for quick fixes
 - Cell/mobile phone
- If taking client on the home evaluation:
- Urinal, as appropriate
 - Blood pressure cuff, stethoscope, gloves

levels of organization. Like any other performance area, the OT will break down the activity into small tasks and focus treatment on building skills for each component of the task. Caregivers may require training if the role of financial manager is new and must be assumed. In the case of Mrs. Hayes, she is having slight cognitive deficits and handwriting difficulties. She may need to teach her husband how to manage bill paying or they may choose to work together. The client may be capable of handling only small amounts of money or may need retraining in activities that require money management, such as shopping, balancing a checkbook, or making a budget. If a physical limitation is involved, the therapist may introduce adaptive writing devices to allow the client to handle the paperwork aspects of money management.

Community Mobility

The occupational therapist also evaluates the client's potential to participate in the community where some type of community mobility is required. Zahoransky⁴⁵ identified community mobility in the following categories:

- Walking with or without the use of an ambulation aid, such as a cane or walker
- Using wheeled mobility devices (i.e., bicycle, motorcycle)
- Using a powered device, such as a power wheelchair or scooter
- Riding as a passenger, with a family, friend, or caregiver as primary transport
- Driving oneself in a vehicle that may or may not be adapted [see [Chapter 11](#)]
- Using public transportation, such as taxi, bus, van, subway, airplane, and other transit systems

The occupational therapist must assess the client's physical, perceptual, cognitive, functional, and social capabilities

to be independent and safe with community mobility. The OT should also be familiar with the environment where the client lives and accesses the community. It is not always possible to know about the client's community or neighborhood from an inpatient or outpatient setting. In this case, the OT has the opportunity to teach the client and caregiver about how to evaluate access and environmental obstacles to help prepare for return to community participation. The OT may also inform the family of needed resources that will help the client resume or learn community access skills.

Physical capabilities to be considered are (1) whether the client has the endurance to be mobile in the community without fatigue and (2) whether the client is sufficiently independent with the walker, cane, crutch, or wheelchair skills and transfers needed to go beyond the home environment. These skills include managing uneven pavement, curbs, and inclines and crossing the street. Other functional skills to be evaluated before considering community mobility are how to (1) handle money, (2) carry objects in a wheelchair or with a walker, and (3) manage toileting in a public restroom.

Cognitive skills include the ability to be geographically and topographically oriented; if taking a bus, to know how to read a schedule and map or know how to get directions; and to have good problem-solving skills if a problem should occur in the community.

If the disability is new, the client may need to develop new social skills or relearn them. At first, these skills will be stretched to the limit once the client is out in the community—for example, learning how to be assertive to get an accessible table at a restaurant, obtaining assistance with unreachable items in the grocery store, and becoming comfortable with a new body image within the able-bodied community.

Visual spatial skills are critical to safety in judging distance stepping down from a curb, driving a car, maneuvering a wheelchair on a narrow sidewalk. The visual spatial skills are identified during an evaluation, considered in relationship to the cognitive, physical, and functional deficits the client exhibits. Some individuals have awareness of their deficits and compensate well. Others are not aware of the deficits or have difficulty with compensatory strategies and therefore will require greater supervision with community mobility than others.

The therapist should also assess the client's community environment. For example, is the neighborhood safe enough for an individual who might be vulnerable because of physical limitations? What is the terrain like? Are there curb cutouts? Are the sidewalks smooth and even? How far away are the closest store and bus stop? Are the traffic lights long enough for the client to negotiate safely given mobility limitations?

Accessibility of community transportation should also be considered. Some communities have door-to-door cab and van service, which have certain restrictions. Some of these restrictions include the need to arrange transportation a

week in advance, the ability to get out the front door and to the curb independently, and the ability to transfer independently into the vehicle. If the client is to use a public bus, he or she must learn how to use the electric lifts and how to lock a wheelchair into place. Because not all bus stops are wheelchair accessible, the neighboring bus stops should be surveyed.

Community mobility requires preplanning by the occupational therapist and the client; accurate assessment of the client's abilities; and knowledge of potential physical, cognitive, visual perceptual, and social barriers that the client may encounter. Armstrong and Lauzen's Community Integration Program⁶ is a valuable resource for providing practical treatment protocols to establish a community-living skills program. Attaining independence in community mobility allows the client to expand life tasks beyond those in the home and allows participation in the community.

Health Management and Maintenance

Health management and maintenance include the client's ability to understand the medical condition and make decisions to maintain good health and avoid behaviors that compromise health.³ The client's ability to handle medications, know when to call a physician, and know how to make a medical appointment are practical aspects of health management. The evaluation of the client's ability to perform these activities may be completed solely by the occupational therapist but will probably include other team members such as the nurse and the physician. The information provided by the occupational therapist's skilled evaluation of the client's cognition, visual perception, and physical abilities can greatly enhance the skilled nurse's ability to use appropriate interventions and teaching strategies when teaching medication management to the client.

Performance skills and patterns must be assessed in light of the skills required for each task. The OT assessment can be helpful in determining which aspects of the task need to be modified for the client to be independent. For example, the occupational therapist can work jointly with a nurse to ensure that a client with hemiplegia and diabetes can manage insulin shots. The OT evaluation considers the client's cognitive and perceptual abilities to make judgments about drawing the insulin out of the bottle, measuring the insulin, and injecting the insulin. Physical concerns include how to stabilize the insulin bottle, accurately see the measurement, and handle the syringe with one hand. Other medication management may involve how the client is able to open the medication and measure it, if the medication is a liquid. The occupational therapist may also evaluate and train the client in other skills that affect health management. Examples include using the phone, finding the appropriate phone numbers, and providing the needed information to make a medical appointment.

Because she has paraplegia, Anna's new health management and maintenance routine may be to perform regular skin checks and weight shifts to prevent decubiti (pressure

sores) from developing. An occupational therapist can help Anna to obtain necessary adaptive aids and strategies to ensure good skin health.

Health maintenance is an issue for the client and entire healthcare team. The occupational therapist plays an important role because of the scope of the ADL and IADL assessments, which may identify and help resolve problems related to health maintenance.

ADL and IADL Training

If it is determined after an assessment that ADL and IADL training are to be initiated, it is important to establish appropriate short- and long-term goals, based on the assessment and on the client's priorities and potential for independence. The following sequence of training for self-care activities is suggested: feeding, grooming, continence management, transfer skills, toileting, undressing, dressing, and bathing. This sequence is based on the normal development of self-care independence in children. It provides a good guide but may have to be modified to accommodate the specific dysfunction and the capabilities, limitations, and personal priorities of the client.

The occupational therapist should estimate which ADL and IADL tasks are possible and which are not within the client's potential to achieve. The therapist should explore with the client the use of alternative methods of performing the activities, environmental modifications to support safety and independence, and the use of any assistive devices that may be helpful. He or she should determine for which tasks the client requires assistance and how much should be given. It may not be possible to estimate these factors until training is under way.

The ADL and IADL training program may be graded by beginning the intervention with a few simple tasks and gradually increasing the number and complexity of tasks taught. Training should progress from dependent to assisted to supervised to independent, with or without assistive devices. The rate at which grading can occur depends on the client's potential for recovery, endurance, skills, and motivation.⁴

Methods of Teaching ADLs

The therapist must tailor methods of teaching the client to perform daily living tasks to suit each client's learning style and ability. The client who is alert and grasps instructions quickly may be able to perform an entire process after a brief demonstration and oral instruction. Clients who have perceptual problems, poor memory, and difficulty following instructions of any kind need a more concrete, step-by-step approach, reducing the amount of assistance gradually as success is achieved. For these clients it is important to break down the activity into small steps and progress through them slowly, one at a time. A slow demonstration of the task or step by the therapist in the same plane and in the same manner in which the client is expected to perform is

helpful. Oral instructions to accompany the demonstration may or may not be helpful, depending on the client's receptive language skills and ability to process and integrate two modes of sensory information simultaneously. See [Chapter 7](#) for further discussion of teaching activities in occupational therapy.

Touching body parts to be moved, dressed, bathed, or positioned; passive movement of the part through the desired pattern to achieve a step or a task; and gentle manual guidance through the task are helpful tactile and kinesthetic modes of instruction (see [Chapter 7](#)). These techniques can augment or replace demonstration and oral instruction, depending on the client's best avenues of learning. It is necessary to perform a step or complete a task repeatedly to achieve skill, speed, and have a task that is currently declarative learning (consciously knowing what to do) become automatic/procedural learning (unconsciously knowing how to do it). Tasks may be repeated several times during the same training session if time and the client's physical and emotional tolerance allow, or they may be repeated daily until the desired retention or level of skill is achieved.

The process of backward chaining can be used in teaching ADL skills. In this method, the therapist assists the client until the last step of the process is reached. The client then performs this step independently, which affords a sense of success and completion. When the last step is mastered, the therapist assists until the last two steps are reached and the client then completes these two steps. The process continues, with the therapist offering less and less assistance and the client performing successive steps of the task, from last to first, independently.

Before beginning training in any ADL, the occupational therapist must prepare by providing adequate space and arranging equipment, materials, and furniture for maximal convenience and safety. The occupational therapy practitioner should be thoroughly familiar with the task to be performed and any special methods or assistive devices that will be used in its performance. The occupational therapist should be able to perform (or know how to perform) the task as skillfully as he or she expects the client to perform it. After preparation, the activity is presented to the client, usually in one or more of the modes of guidance, demonstration, and oral instruction described earlier. The OT ensures appropriate environmental set up for success and safety. For example, a chair with arms or safely locked wheelchair may be provided to start. The client's feet are placed flat on the floor or, at times if using a wheelchair, on the footplates. Personal care items are located within safe reaching distance when initially learning an activity. The client then performs the activity either along with the occupational therapist or immediately after being shown, with the required amount of supervision and assistance. Performance is modified and corrected as needed and the process is repeated to ensure learning.

Because other staff or family members are frequently reinforcing the newly learned skills, staff and family training

is critical to reinforce learning and ensure that the client carries over the skills from previous treatment sessions. In the final phase of instruction, when the client has mastered one or more tasks, he or she is asked to perform them independently. The therapist should check performance in progress and later arrange to check on the adequacy of performance and carryover of learning with the client, the nursing personnel, the caregiver, or the supervising family members.

Recording Progress in ADL Performance

The ADL checklists used to record performance on the initial assessment usually have one or more spaces for recording changes in abilities and the results of reassessment during the training process. The sample checklist given earlier in this chapter is so designed and completed for illustration purposes using Mrs. Hayes's information (see Figure 10-1). If a standardized assessment is used during the initial evaluation, it should be used in the reevaluation process to objectively measure the level of progress the client has made.

Progress is usually summarized for inclusion in the medical record. The progress record should summarize changes in the client's abilities and current level of independence and should also estimate the client's potential for further independence, attitude, motivation for ADL training, and future goals for the ADL program. The information about the client's level of assistance needed for ADLs and IADLs will help with the discharge planning. For example, if a client continues to require moderate assistance with self-care, he or she may need to hire an attendant, or the occupational therapist may justify ongoing treatment when the client has potential for further independence.

Assistive Technology and Adaptive Equipment

Assistive technology is defined as any item, piece of equipment, or product system, whether acquired commercially, off the shelf, modified, or customized, that is used to increase or improve functional capabilities of individuals with disabilities. This is a definition provided in Public Law (PL) 100-47, the Technical Assistance to the States Act.³⁰ The terms *assistive technology*, *adaptive equipment*, and *assistive devices* are generally used interchangeably throughout the profession. Adaptive equipment is used to compensate for a physical limitation, to promote safety, and to prevent joint injury. Electronic aids to daily living (EADLs) provide a bridge between an individual with limited function and an electrical device such as a telephone or door operator.³⁰ Physical limitations may include a loss of muscle strength, loss of range of motion (ROM), incoordination, or sensory loss. An example of using adaptive equipment to improve safety is the use of a bed or door alarm to alert a caregiver that a patient with impaired cognition and poor balance is wandering. The use of adaptive equipment to prevent joint injury is indicated for the person with rheumatoid arthritis, such as a built-up handled eating utensil.

Before recommending a piece of adaptive equipment, the OT practitioner must complete a thorough assessment to determine the client's functional problems and causes of the problems. The OT practitioner may also consider practical solutions first, before settling on adaptive equipment as the solution. Some practical solutions would be to avoid the cause of the problem, use a compensatory technique or alternative method, get assistance from another person, or modify the environment. Typical of these considerations is the case example of Ms. Robins (who will be discussed in the case that follows) where the environment was adapted, wheelchair positioning/setup adapted, and a compensatory strategy of propping her elbows on the table was used instead of adaptive equipment.

Other factors to consider when selecting adaptive equipment are whether the disability is short or long term, the client's tolerance for gadgets, the client's feelings about the device, and the cost and upkeep of the equipment.

Case Study Ms. Robins

Ms. Robins is 75 years old and living in a nursing home. The occupational therapist received a referral for a self-feeding assessment because she has recently lost weight and the nursing aides have reported that she needs assistance with eating. The nurse mentioned that she thought Ms. Robins needed a utensil with a built-up handle to feed herself.

The OT assessment included an interview with Ms. Robins, observation of her eating lunch in her usual location (in her room with the use of an over-bed table), physical assessment (including strength, ROM, sensation, coordination), and gross cognitive and perceptual assessments. Ms. Robins stated that she would like to be able to feed herself because she likes to eat her food when it is hot and she likes to be as independent as possible. The results indicated that Ms. Robins had problems with sitting properly in her wheelchair. The over-bed table was too high and limited her ability to reach the plate. Her strength, ROM, coordination, and sensation were within normal limits, except that bilateral shoulder flexors and abductors were F- (3-). Ms. Robins's cognition and perception were adequate to relearn simple self-care tasks.

Treatment involved working on wheelchair positioning, lowering the over-bed table, and then teaching the client how to use a compensatory technique of elbow propping to bring her hand to her mouth during eating. The OT assessment did not indicate a need for adaptive equipment at this time; instead, the environment was adapted, wheelchair positioning modified, and a compensatory method taught.

If the results of the assessment had indicated that Ms. Robins had a weak grasp or hand incoordination, a utensil with a built-up handle and plate guard might have been used to promote independence with self-feeding.

Specific ADL and IADL Techniques

In many instances, specific techniques to solve specific ADL problems are not possible. Sometimes the occupational therapist has to explore a variety of methods or assistive devices to reach a solution. It is occasionally necessary for the therapist to design a special device, method, splint, or piece of equipment to make a particular activity possible for the client to perform. Many of the assistive devices available today through rehabilitation equipment companies were first conceived and made by occupational therapists and clients. Many of the special methods used to perform specific activities also evolved through the trial-and-error approaches of therapists and their clients. Clients often have good suggestions for therapists, because they live with the limitation and are confronted regularly with the need to adapt the performance of daily tasks.

The purpose of the following summary of techniques is to give the reader some general ideas about how to solve ADL and IADL problems for specific classifications of dysfunction. The focus is on compensatory strategies involving changing the method in which an activity is performed, changing the environment, or using an assistive device. If the client has the potential for improvement of specific deficits, treatment that includes remediation and restoration should be considered. For example, if a client has hand weakness as a result of a fracture of his hand, the therapist may offer alternative methods and adaptive equipment to manage until strength improves, but hand strengthening should also be a component of the treatment program. The references at the end of this chapter provide more specific instruction in ADL and IADL methods. The following categories of physical deficits are addressed in this chapter for the person with the following conditions:

- Limited ROM or strength
- Incoordination
- Hemiplegia or use of only one upper extremity
- Paraplegia
- Quadriplegia
- Low vision
- Exceptionally large size body (bariatric population)

The following ADLs and IADLs are addressed with each of the physical deficits previously listed:

- Dressing activities
- Feeding activities (eating and swallowing are addressed in [Chapter 27](#))
- Personal hygiene and grooming activities
- Communication management and environmental adaptations
- Functional mobility (transfers and wheelchair mobility are addressed in [Chapter 11](#))
- Home management, meal preparation, and cleanup activities

ADLs for the Person with Limited ROM or Strength

The major problem for persons with limited joint ROM is compensating for the lack of reach and joint excursion through such means as environmental adaptation and assistive devices. Individuals who lack muscle strength may require some of the same devices or techniques to compensate and to conserve energy. Some adaptations and devices are outlined here.^{22,36}

Lower-Extremity Dressing Activities

1. Use dressing sticks with a neoprene-covered coat hook on one end and a small hook on the other ([Figure 10-7](#)) for pushing and pulling garments off and on feet and legs.

FIGURE 10-7 Collapsible dressing stick.
(Courtesy North Coast Medical Inc.)

FIGURE 10-8 Easy pull sock aid.
(Courtesy North Coast Medical Inc.)

FIGURE 10-9 Extended handle reacher.
(Courtesy North Coast Medical Inc.)

2. For socks, use a commercially available sock aid (Figure 10-8).
3. Eliminate the need to bend to tie shoelaces or to use finger joints in this fine motor activity by using elastic shoelaces or other adapted shoe fasteners such as Velcro-fastened shoes or secure slip-on shoes.
4. Use reachers (Figure 10-9) for picking up socks and shoes, arranging clothes, removing clothes from hangers, picking up objects on the floor, and donning pants.

FIGURE 10-10 Button hook with built-up handle.
(Courtesy North Coast Medical Inc.)

Upper-Extremity Dressing Activities

1. Use front-opening garments that are one size larger than needed and made of fabrics that have some stretch.
2. Use dressing sticks (see Figure 10-7) to push a shirt or blouse over the head.
3. Use larger buttons or zippers with a loop on the pull-tab.
4. Replace buttons, snaps, hooks, and eyes with Velcro or zippers (for those clients who cannot manage traditional fastenings).
5. Use one of several types of commercially available buttonhooks (Figure 10-10) if finger ROM is limited.

Feeding Activities

1. Use built-up handles on eating utensils that can accommodate limited grasp or prehension (grip or pinch pattern) (Figure 10-11).
2. Elongated or specially curved handles on spoons and forks may be needed to reach the mouth. A swivel spoon or spoon-fork combination can compensate for limited supination (see Figure 10-11).
3. Long plastic straws and straw clips on glasses or cups can be used if neck, elbow, or shoulder ROM limits hand-to-mouth motion or if grasp is inadequate to hold the cup or glass.

FIGURE 10-11 Fork with built-up handle and swivel.
(Courtesy North Coast Medical Inc.)

4. Universal cuffs or utensil holders can be used if grasp is very limited and built-up handles are not sufficient (Figure 10-12).
5. Plate guards or scoop dishes may be useful to prevent food from slipping off the plate.

Personal Hygiene and Grooming Activities

1. A handheld flexible shower hose for bathing and shampooing hair can eliminate the need to stand in the shower and offers the user control of the direction of the spray. The handle can be built up or adapted for limited grasp.
2. A long-handled bath brush or sponge with a soap holder (Figure 10-13) or long cloth scrubber can allow the user to reach legs, feet, and back. A wash mitt (Figure 10-14) and soap on a rope can aid limited grasp. If reach is limited to wash hair, a soft rubber brush with extended handle or specially designed long-handled adaptive aid can be used to shampoo hair.
3. A wall-mounted hair dryer may be helpful. This device is useful for clients with limited ROM, upper-extremity weakness, incoordination, or use of just one upper extremity. The dryer is mounted (wall or stand) to allow the user to manage his or her hair with one arm or position himself or herself to compensate for limited ROM.
4. Long handles on a comb, brush, toothbrush, lipstick, mascara brush, and safety or electric razor may be useful for clients with limited hand-to-head or hand-to-face movements. Extensions may be constructed from inexpensive wooden dowels or pieces of PVC pipe found in hardware stores. The handles can be built up or adapted for limited grasp.
5. Spray deodorant, hair spray, and spray powder or perfume can extend the reach by the distance the material sprays.

FIGURE 10-12 Universal cuff.
(Courtesy North Coast Medical Inc.)

6. Electric toothbrushes and a Water-Pik may be easier to manage than a standard toothbrush; each may need to be adapted for limited grasp.
7. A short reacher can extend reach for using toilet paper. Several types of toilet aids are available in catalogs that sell assistive devices.
8. Dressing sticks can be used to pull garments up after using the toilet. An alternative is the use of a long piece of elastic or webbing with clips on each end that can be hung around the neck and fastened to pants or panties, preventing them from slipping to the floor during use of the toilet.
9. Safety rails (Figure 10-15) can be used for bathtub transfers, and safety mats or strips can be placed in the bathtub bottom to prevent slipping.

FIGURE 10-13 Long-handed brush.
(Courtesy Patterson Medical.)

FIGURE 10-14 Bath mitt.
(Courtesy North Coast Medical Inc.)

10. A transfer tub bench (see [Figure 10-6](#)), shower stool, or regular chair set in the bathtub or shower stall can eliminate the need to sit on the bathtub bottom or stand to shower, thus increasing safety.
11. Grab bars can be installed to prevent falls and ease transfers.
12. Pump dispensers for shampoo, conditioners, and lotions are easier to manage than containers that require lifting and pouring contents. If using containers that require lifting and pouring, use smaller containers and transfer contents from larger containers to smaller ones.

FIGURE 10-15 Tub safety rail.
(Courtesy North Coast Medical Inc.)

Communication and Environmental Hardware Adaptations

1. Extended built-up or lever handles on faucets can accommodate limited grasp.
2. Telephones should be placed within easy reach, or portable phones can be used and kept with the client. A speakerphone or headset may be necessary. A dialing stick is or use of phones with large push buttons may be helpful if individual finger movements are difficult or not possible.
3. Built-up pens and pencils can be used to accommodate limited grasp and prehension. A Wanchik writer and several other commercially available or custom-fabricated writing aids are available ([Figure 10-16](#)).
4. Personal computers, word processors, voice recognition computer software, book holders, and electronic books can facilitate communication for those with limited or painful joints.
5. Lever-type doorknob extensions ([Figure 10-17](#)), commercially available lever-style doorknobs, car door openers, and adapted key holders can compensate for hand limitations.

Functional Mobility

The individual who has limited ROM without significant muscle weakness may benefit from the following assistive devices:

1. A glider chair that is operated by the feet can facilitate transportation if hip, hand, and arm motion is limited.

FIGURE 10-16 Wanchik writer.
(Courtesy North Coast Medical Inc.)

2. Platform crutches can prevent stress on hand or finger joints and can accommodate limited grasp. Confer with the physical therapist about this option as platform crutches may increase the weight and size of the walking aid and may actually be a detriment to the client's gait or may increase pressure on the shoulder.
3. Enlarged grips on crutches, canes, and walkers can accommodate limited grasp. Confer with the physical therapist about this option.
4. A raised toilet seat can be used if hip and knee motion is limited.
5. A walker with padded grips and forearm troughs can be used if marked hand, forearm, or elbow joint limitations are present. Confer with the physical therapist about this option.
6. A walker or crutch bag, tray, or basket can facilitate the carrying of objects.

Home Management, Meal Preparation, and Cleanup Activities

Home management activities can be facilitated by a wide variety of environmental adaptations, assistive devices, energy conservation methods, and work simplification techniques.^{8,36} The principles of joint protection are essential for those with rheumatoid arthritis. These principles are discussed in [Chapter 38](#). The following are suggestions to facilitate home management for persons with limited ROM:

FIGURE 10-17 Door knob extension.
(Courtesy North Coast Medical Inc.)

1. Store frequently used items on the first shelves of cabinets, just above and below counters or on counters where possible. Eliminate unnecessary items.
2. Use a high stable stool to work comfortably at counter height with feet firmly placed on the ground, or attach a drop-leaf table to the wall for planning and meal preparation area if a wheelchair is used. Pull out breadboards can also serve as a wheelchair accessible countertop workspace.
3. Use a utility cart of comfortable height to transport several items at once.
4. Use reachers to get lightweight items (e.g., a cereal box) from high shelves. Place frequently used items on shelves in cabinets and refrigerator where items are easily accessible and reachable.
5. Stabilize mixing bowls and dishes with nonslip mats.

A

B

FIGURE 10-18 A, Round-tip scissors. B, Loop scissors. (Courtesy North Coast Medical Inc.)

6. Use lightweight utensils, such as plastic or aluminum bowls and aluminum pots. Use lightweight plates, cups, and other serving containers.
7. Use an electric can opener and an electric mixer.
8. Use electric scissors or adapted loop scissors to open packages (Figure 10-18). Avoid using teeth to rip open packages, as this may wear down, weaken, or break teeth.
9. Eliminate bending by using extended and flexible plastic handles on dust mops, brooms, and dustpans.
10. Use adapted knives for cutting (Figure 10-19), or consider using precut vegetables and meat for cooking.

FIGURE 10-19 Right-angle rocker knife. (Courtesy Sammons Preston.)

11. Use pullout shelves or lazy Susans to organize cupboards or refrigerator to eliminate bending and to ease access to items.
12. Eliminate bending by using a wall oven, countertop broiler, microwave oven, and convection oven. When remodeling the kitchen, consider elevating the dishwasher to a convenient height for wheelchair use or for those who have difficulty bending.
13. Use pump dispensers for dish soap instead of dish soap containers with pour spouts, which require lifting and pouring of contents. Single-use, premeasured water-soluble dishwasher detergent packets eliminate numerous steps.
14. Use piece of Dycem or other nonslip materials such as piece of puffy shelf liner or thick rubber band around jar lid or jar openers to open containers. Keep these handy in multiple locations.
15. Eliminate leaning and bending by using a top-loading automatic washer and elevated dryer. Wheelchair users or people of shorter stature can benefit from front-loading appliances. Use a reacher or other extended tool to reach to obtain clothes from the washer or dryer.
16. Use an adjustable ironing board to make it possible to sit while ironing, or eliminate ironing with the use of permanent press clothing.
17. Elevate the playpen and diaper table and use a bathinette (portable folding baby bath tub) or a plastic tub on the kitchen counter for bathing to reduce the amount of bending and reaching by the ambulatory parent during child care. The crib mattress can be in a raised position until the child is 3 or 4 months of age.
18. Use slightly larger and looser fitting garments with Velcro fastenings on children.
19. Use a reacher to pick up items from floor.
20. Use a comforter instead of a top sheet and blanket to increase the ease of making the bed.

ADLs for the Person with Incoordination

Incoordination in the form of tremors, ataxia, athetoid, or choreiform movements can be caused by a variety of central nervous system (CNS) disorders, such as Parkinson's disease, multiple sclerosis, cerebral palsy, Freidrich's ataxia, and head injuries. The major problems encountered in ADL performance are safety and adequate stability of gait, body parts, and objects to complete the tasks.^{22,31}

Fatigue, stress, emotional factors, and fear may influence the severity of incoordinated movement.²² The client must be taught appropriate energy conservation and work simplification techniques along with appropriate work pacing and safety methods to prevent the fatigue and apprehension that could increase incoordination and affect performance.

Stabilizing the arm reduces some of the incoordination and may allow the individual to accomplish gross and fine motor movements without assistive devices. A technique that can be used throughout all ADL tasks is the stabilization of the involved upper extremity. This technique is accomplished by propping the elbow on a counter or tabletop, pivoting from the elbow, and only moving the forearm, wrist, and hand in the activity. When muscle weakness is not a major deficit for the individual with incoordination, the use of weighted devices can help with stabilization of objects. A Velcro-fastened weight can be attached to the client's arm or to the back of the client's hand to decrease ataxia, or the device being used (e.g., eating utensils, pens, and cups) can be weighted.³¹

Dressing Activities

To avoid balance problems, the client should attempt to dress while sitting on or in bed or in a wheelchair or chair with arms and feet planted firmly on floor. The following adaptations can reduce dressing difficulties:

1. Use of front-opening garments that fit loosely can facilitate their donning and removal.
2. Use of large buttons, Velcro, or zippers with loops on the tab can facilitate opening and closing fasteners. A buttonhook with a large, weighted handle may be helpful.
3. Elastic shoelaces, Velcro closures, other adapted shoe closures, and slip-on shoes eliminate the need for bow tying.
4. Slacks with elastic tops for women or Velcro closures for men are easier to manage than slacks with hooks, buttons, and zippers.
5. Using bras with front openings or Velcro replacements for the usual hook and eye may make it easier to don and remove these garments. A slipover elastic-type bra or bra-slip combination also may eliminate the need to manage bra fastenings. Regular bras may be fastened in front at waist level, then slipped around to the back and the arms put into

the straps, which are then worked up over the shoulders.

6. Men can use clip-on ties.^{1,31}

Feeding Activities

Feeding can be a challenge for clients with problems of incoordination. A lack of control during eating is not only frustrating, but can also cause embarrassment and social rejection. It is important to make eating safe, pleasurable, and as neat as possible. The following are some suggestions for achieving this goal:

1. Use plate stabilizers, such as nonskid mats (Dycem), suction bases, or even damp dishtowels.
2. Use a plate guard or scoop dish to prevent pushing food off the plate. The plate guard can be carried away from home and clipped to any ordinary dinner plate (Figure 10-20).
3. Prevent spills during the plate-to-mouth excursion by using weighted or swivel utensils to offer stability. Weighted cuffs may be placed on the forearm or glove with weights on the back of the hand to decrease involuntary movement).
4. Use long plastic straws with a straw clip on a glass, or use a cup with a weighted bottom to eliminate the need to carry the glass or cup to the mouth, thus avoiding spills. Plastic cups with covers and spouts may be used for the same purpose^{22,31} (Figure 10-21).
5. Use a resistance or friction feeder similar to a mobile arm support to help control patterns of involuntary movement during feeding activities of adults with cerebral palsy and athetosis. These devices may help many clients with severe incoordination to achieve some degree of independence in feeding. The device is available in adaptive equipment catalogs and is listed as a Friction Feeder MAS (Mobile Arm Support) Kit.

FIGURE 10-20 Plate guard.

(Courtesy Patterson Medical.)

FIGURE 10-21 Cup adaptors.
(Courtesy Patterson Medical.)

6. Use a mechanical self-feeding device that turns the plate, scoops the food, and brings it to the mouth. There are several models available.

Personal Hygiene and Grooming Activities

Stabilization and handling of toilet articles may be achieved by the following suggestions:

1. Articles such as a razor, lipstick, and a toothbrush may be attached to a cord if frequent dropping is a problem. An electric toothbrush may be more easily managed than a regular one. It is important to check the weight, operating mechanisms, and other properties of recommended devices to determine if the client can manage.

FIGURE 10-22 Suction denture brush.
(Courtesy North Coast Medical Inc.)

2. Weighted wrist cuffs may be helpful during the finer hygiene activities, such as hair care, shaving, and applying makeup.³¹
3. A wall-mounted (or stand-mounted) hair dryer described earlier for clients with limited ROM can also be useful for clients with incoordination.
4. An electric razor, rather than a blade razor, offers stability and safety.³¹ A strap around the razor and hand can prevent dropping.
5. A suction brush attached to the sink or counter can be used for nail or denture care (Figure 10-22).
6. Soap should be on a rope. It can be worn around the neck or hung over a bathtub or shower fixture during bathing to keep it within easy reach. A bath mitt with a pocket to hold the soap can be used for washing to eliminate the need for frequent soaping and rinsing and wringing a washcloth. A leg from a pair of light-colored panty hose with a bar of soap in the toe may be tied over a faucet or on a bath chair to keep soap within reach and will stretch for use. Liquid soap with a soft nylon scrubber may be used to minimize the handling of soap. Bath gloves can be worn and liquid soap that is not too slippery applied to eliminate the dropping of the soap and washcloth.³¹
7. An emery board or small piece of wood with fine sandpaper glued to it can be fastened to the tabletop for filing nails.³¹ A nail clipper can be stabilized in the same manner.
8. Large roll-on deodorants are preferable to sprays or creams.³¹

9. Sanitary pads that stick to undergarments may be easier to manage than tampons.³¹
10. Nonskid mats should be used inside and outside the bathtub during bathing. Their suction bases should be fastened securely to the floor and bathtub before use. Safety grab bars should be installed on the wall next to the bathtub or fastened to the edge of the bathtub. A bathtub seat or shower chair provides more safety than standing, while the individual is showering or transferring to a bathtub bottom.³¹ Many clients with incoordination require supervisory assistance during this hazardous activity. Sponge bathing while seated at a bathroom sink may be substituted for bathing or showering several times a week.

Communication and Environmental Hardware Adaptations

1. Doorknobs may be managed more easily if adapted with lever-type handles or covered with rubber or friction tape (see Figure 10-17).
2. Large button phones, speakerphones, or a holder for a telephone receiver may be helpful. Operator assistance services for dialing may be implemented.
3. Mobile phones or personal digital assistants should be selected based on need for larger key pads and voice dialing capabilities.
4. Writing may be managed by using a weighted, enlarged pencil or pen. A personal computer with a keyboard guard is a helpful aid to communication. A computer mouse may frequently be substituted for the keyboard.³¹ A voice-recognition program may be used with a personal computer to minimize use of the keyboard or mouse. Most computers have “accessibility” features as a choice on the control panels. These features allow for adjustments such as decreasing sensitivity of the keys to eliminate redundancy of keystrokes and sensitivity of the mouse.
5. Keys may be managed by placing them on an adapted key holder that is rigid and offers more leverage for turning the key. Inserting the key in the keyhole may be difficult, however, unless the incoordination is relatively mild. Locks to cars and homes can be modified with keypads or electronic door openers.
6. Extended lever-type faucets are easier to manage than knobs that turn and push-pull spigots. In order to prevent burns during bathing and kitchen activities, the person with incoordination should turn cold water on first and add hot water gradually.
7. Lamps that can be turned on and off with a wall switch, a light, a signal-type device, or by touch can eliminate the need to turn a small switch.

Functional Mobility

Clients with problems of incoordination may use a variety of ambulation aids, depending on the type and severity of incoordination. Clients with degenerative diseases sometimes need help to recognize the need for and to accept ambulation aids. This problem may mean moving gradually from a cane to crutches to a walker, and finally to a wheelchair for some persons. The following suggestions can improve stability and mobility for clients with incoordination:

1. Instead of lifting objects, slide them on floors or counters.
2. Use suitable ambulation aids.
3. Use a utility cart, preferably a heavy, custom-made cart that has some friction on the wheels.
4. Remove doorsills or thresholds, throw rugs, and thick carpeting.
5. Install banisters on indoor and outdoor staircases.
6. Substitute ramps for stairs wherever possible.

Home Management, Meal Preparation, and Cleanup Activities

It is important for the occupational therapist to carefully assess performance of homemaking activities to determine (1) which activities can be done safely, (2) which activities can be done safely if modified or adapted, and (3) which activities cannot be done adequately or safely and should be assigned to someone else. The major problems are stabilization, handling and moving hot items, and use of sharp tools. These problems need to be addressed to prevent spilling and accidents, cuts, burns, bruises, electric shock, and falls. The following are suggestions for facilitating home management tasks:^{17,22,31}

1. Use a wheelchair and wheelchair lapboard, even if ambulation is possible with devices. The wheelchair saves energy and increases stability if balance and gait are unsteady.
2. If possible, use convenience and prepared foods to eliminate as many processes (e.g., peeling, chopping, slicing, and mixing) as possible.
3. Use easy-opening containers or store foods in plastic containers once opened. A jar opener is also useful.
4. Use heavy utensils, mixing bowls, and pots and pans to increase stability.
5. Use nonskid mats on work surfaces.
6. Use electrical appliances such as crock pots, electric fry pans, toaster ovens, and microwave or convection ovens because they are safer than using a range-top stove.
7. Use a blender and countertop mixer because they are safer than handheld mixers and easier than mixing with a spoon or whisk.
8. If possible, adjust work heights of counters, sink, and range to minimize leaning, bending, reaching, and

FIGURE 10-23 Cutting board.
(Courtesy Patterson Medical.)

lifting, whether the client is standing or using a wheelchair.

9. Use long oven mitts, which are safer than potholders.
10. Use pots, pans, casserole dishes, and appliances with bilateral handles because they may be easier to manage than those with one handle.
11. Use an adapted cutting board with side rails ([Figure 10-23](#)) to stabilize meats and vegetables while cutting. The bottom of the board should have suction cups or should be covered with stair tread, or the board should be placed on a nonskid mat to prevent slippage when in use.
12. Use heavy dinnerware, which may be easier to handle because it offers stability and control to the distal part of the upper extremity. On the other hand, unbreakable dinnerware may be more practical if dropping and breakage are problems.
13. Cover the sink, utility cart, and countertops with protective rubber mats or mesh matting to stabilize items.
14. Use a serrated knife for cutting and chopping because it is easier to control.
15. Use a steamer basket or deep-fry basket for preparing boiled foods to eliminate the need to carry and drain pots containing hot liquids.
16. Use tongs to turn foods during cooking and to serve foods because tongs may offer more control and stability than a fork, spatula, chopsticks, or serving spoon.
17. Use blunt-ended loop scissors to open packages.
18. Vacuum with a heavy upright cleaner, which may be easier for the ambulatory client. The wheelchair user may be able to manage a lightweight tank-type vacuum cleaner or electric broom.
19. Use dust mitts for dusting.

20. Eliminate fragile knickknacks, unstable lamps, and dainty doilies.
21. Eliminate ironing by using no-iron fabrics or a timed dryer or by assigning this task to other members of the household. Lower ironing board so that the task can be accomplished from a seated position.
22. Use a front-loading washer, a laundry cart on wheels, and premeasured detergents, bleaches, and fabric softeners.
23. Sit when working with an infant and use foam-rubber bath aids, an infant bath seat, and a wide, padded dressing table with Velcro safety straps to offer enough stability for bathing, dressing, and diapering an infant. Childcare tasks may not be possible unless the incoordination is mild.
24. Use disposable diapers with tape or Velcro fasteners, because they are easier to manage than cloth diapers and pins.
25. Do not feed the infant with a spoon or fork unless the incoordination is very mild or does not affect the upper extremities. This task may need to be performed by another household member.
26. Children's clothing should be large, loose, and made of nonslippery stretch fabrics, and should have Velcro fastenings.
27. Use front infant carriers or strollers for carrying.

ADLs for the Person with Hemiplegia or Use of Only One Upper Extremity

Suggestions for performing daily living skills apply to persons with hemiplegia, unilateral upper-extremity amputations, and temporary disorders such as fractures, burns, and peripheral neuropathic conditions that can result in the dysfunction of one upper extremity.

The client with hemiplegia needs specialized methods of teaching, and many such clients have greater difficulty learning and performing one-handed skills than do those with orthopedic or lower motor neuron dysfunction. Because the trunk and leg are involved, as well as the arm, ambulation and balance difficulties may exist. Sensory, perceptual, cognitive, and speech disorders may be present in a mild to severe degree. These disorders affect the ability to learn and retain learning and performance. Finally, the presence of apraxia (or difficulty with motor planning) sometimes seen in this group of clients can have a profound effect on the potential for learning new motor skills and remembering old ones. Therefore, the client with normal perception and cognition and the use of only one upper extremity may learn the techniques quickly and easily. The client with hemiplegia needs to be assessed for sensory, perceptual, and cognitive deficits to determine the potential for ADL performance and to establish appropriate teaching methods to facilitate learning. The following are primarily adaptive techniques versus restorative techniques. However, it is

important to incorporate the upper extremity with hemiplegia to assist in returning functional to the extremity.

The major problems for the one-handed worker are reduction of work speed and dexterity and stabilization to substitute for the role normally assumed by the nondominant arm.²² The major problems for the individual with hemiplegia are balance and precautions relative to sensory, perceptual, and cognitive losses.

Dressing Activities

General Setup

If balance is a problem, the client should dress while seated in a locked wheelchair or sturdy armchair. Clothing should be within easy reach. A reacher may be helpful for securing articles and assisting in some dressing activities. Assistive devices should be used minimally for dressing and other ADLs. Compensatory techniques are preferable to using unnecessary devices. For the client with hemiplegia, dressing techniques that employ neurodevelopmental treatment (NDT or Bobath) principles are discussed in [Chapter 31](#). The following one-handed dressing techniques can facilitate dressing for persons with use of only one upper extremity. A general rule is to begin with the affected arm or leg first when donning clothing. Start with the unaffected extremity when doffing (removing) clothing. The following list summarizes the general setup:

- Sturdy chair or wheelchair (and progress to more difficult surfaces)
- Clothing within easy reach; adaptive equipment set up and within reach
- Feet (or foot) supported on floor or sturdy surface
- Body usually in upright and in midline position depending on task
- Therapist usually positioned on affected side or in midline

Shirts

One of the three following methods can be used to manage front-opening shirts. The first method can also be used for jackets, robes, and front-opening dresses.

Method I

Donning Shirt

1. Grasp the shirt collar with normal hand and shake out twists ([Figure 10-24, A](#)).
2. Position shirt on lap with inside up and collar toward chest ([Figure 10-24, B](#)).
3. Position sleeve opening on affected side so opening is as large as possible and close to affected hand, which is resting on lap ([Figure 10-24, C](#)).

FIGURE 10-24 Steps in donning a shirt: method I.

(Courtesy Christine Shaw, Metro Health Center for Rehabilitation, Metro Health Medical Center, Cleveland, Ohio.)

4. Using stronger hand, place affected hand in sleeve opening and work sleeve over elbow by pulling on garment (Figure 10-24, D1 and D2).
5. Put stronger arm into its sleeve and raise arm to slide or shake sleeve into position past elbow (Figure 10-24, E).
6. With stronger hand, gather shirt up middle of back from hem to collar and raise shirt over head (Figure 10-24, F).
7. Lean forward, duck head, and pass shirt over head (Figure 10-24, G).
8. With stronger hand, adjust shirt by leaning forward and working shirt down past both shoulders. Reach in back and pull shirttail down (Figure 10-24, H). Adjust shirt so that shirt is smooth, wrinkles removed, and sleeve is properly placed on shoulders and arms. Someone with hemiplegia may not feel that his or her shirt is not positioned properly on his or her body.
9. Line up shirt fronts for buttoning and begin with bottom button (Figure 10-24, I). Button sleeve cuff of affected arm. Sleeve cuff of stronger arm may be prebuttoned if cuff opening is large. Button may be sewn on with elastic thread or sewn onto a small tab of elastic and fastened inside shirt cuff; also, commercially available button extenders can be found in the adaptive equipment catalogs. A small button attached to crocheted loop of elastic thread is another option. Slip button on loop through buttonhole in garment so that elastic loop is inside. Stretch elastic loop to fit around original cuff button. This simple device can be transferred to each garment and positioned before shirt is put on. Loop stretches to accommodate width of hand as it is pushed through end of sleeve.

Removing Shirt

1. Unbutton shirt.
2. Lean forward.
3. With stronger hand, grasp collar or gather material up in back from collar to hem.
4. Lean forward, duck head, and pull shirt over head.
5. Remove sleeve from stronger arm and then from affected arm.

Method II

Donning Shirt Clients who get their shirts twisted or have trouble sliding the sleeve down onto the stronger arm can use method II.

1. Position shirt as described in method I, steps 1 to 3.
2. With stronger hand, place involved hand into the sleeve opening and work sleeve onto hand, but do not pull up over elbow.
3. Put stronger arm into sleeve and bring arm out to 180 degrees of abduction. Tension of fabric from stronger arm to wrist of affected arm will bring sleeve into position.

4. Lower arm and work sleeve on affected arm up over elbow.
5. Continue as in steps 6 through 9 of method I.

Removing Shirt (One Sleeve off at a Time)

1. Unbutton shirt.
2. With stronger hand, push shirt off shoulders, first on affected side, then on stronger side.
3. Pull off cuff of stronger side with stronger hand.
4. Work sleeve off by alternately shrugging shoulder and pulling down on cuff.
5. Lean forward, bring shirt around back, and pull sleeve off affected arm.

Method III

Donning Shirt

1. Position shirt and work onto arm as described in method I, steps 1 to 4.
2. Pull sleeve on affected arm up to shoulder (Figure 10-25, A).
3. With stronger hand, grasp tip of collar that is on stronger side, lean forward, and bring arm over and behind head to carry shirt around to stronger side (Figure 10-25, B).
4. Put stronger arm into sleeve opening, directing it up and out (Figure 10-25, C).
5. Adjust and button as described in method I, steps 8 and 9.

Removing Shirt The shirt may be removed using the procedure described previously for method II.

Variation for Donning Pullover Shirt

1. Position shirt on lap, bottom toward chest and label facing down.
2. With stronger hand, roll up bottom edge of shirt back up to sleeve on affected side.
3. Position sleeve opening so it is as large as possible, and use stronger hand to place affected hand into

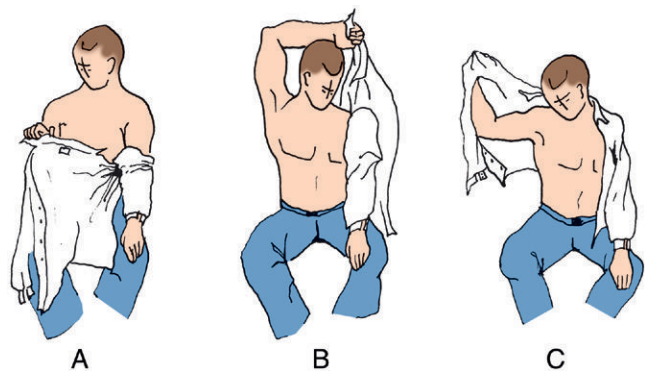

FIGURE 10-25 Steps in donning a shirt: method III.

(Courtesy Christine Shaw, Metro Health Center for Rehabilitation, Metro Health Medical Center, Cleveland, Ohio.)

sleeve opening. Pull shirt up onto weaker arm past the elbow.

4. Insert stronger arm into sleeve.
5. Adjust shirt on affected side up and onto shoulder.
6. Gather shirt back with stronger hand, lean forward, duck head, and pass shirt over head.
7. Adjust shirt. Make sure shirt is adjusted properly on shoulders and in the front and back.

Variation for Removing Pullover Shirt

1. Gather shirt up with stronger hand, starting at top back.
2. Lean forward, duck head, and pull gathered back fabric over head.
3. Remove from stronger arm and then affected arm.

Trousers

Trousers may be managed by one of the following methods, which may be adapted for shorts and women's panties as well. It is recommended that trousers have a well-constructed button fly front opening, which may be easier to manage than a zipper. Velcro may be used to replace buttons and zippers. Trousers should be worn in a size slightly larger than worn previously and should have a wide opening at the ankles. They should be put on after the socks have been

put on but before the shoes are put on. If the client is dressing in a wheelchair, feet should be placed flat on the floor, not on the footrests of the wheelchair.

Method I

Donning Trousers

1. Sit in sturdy armchair or in locked wheelchair (Figure 10-26, A).
2. Position stronger leg in front of midline of body with knee flexed to 90 degrees. Using stronger hand, reach forward and grasp ankle of affected leg or sock around ankle (Figure 10-26, B1). Lift affected leg over stronger leg to crossed position (Figure 10-26, B2).
3. Slip trousers onto affected leg up to position where foot is completely inside trouser leg (Figure 10-26, C). Do not pull up above knee or it will be difficult to insert the stronger leg.
4. Uncross affected leg by grasping ankle or portion of sock around ankle (Figure 10-26, D).
5. Insert stronger leg and work trousers up onto hips as far as possible (Figure 10-26, E1 and E2).
6. To prevent trousers from dropping when pulling pants over hips, place affected hand in pocket or place one finger of affected hand into belt loop.

FIGURE 10-26 Steps in donning trousers: method I.

(Courtesy Christine Shaw, Metro Health Center for Rehabilitation, Metro Health Medical Center, Cleveland, Ohio.)

If able to do so safely, stand and pull trousers over hips (Figure 10-26, F1 and F2).

7. If standing balance is good, remain standing to pull up zipper or button (Figure 10-26, F3). Sit down to button front (Figure 10-26, G).

Removing Trousers

1. Unfasten trousers and work down on hips as far as possible while seated.
2. Stand, letting trousers drop past hips, or work trousers down past hips.
3. Remove trousers from stronger leg.
4. Sit and cross affected leg over stronger leg, remove trousers, and uncross leg.

Method II

Donning Trousers Method II is used for clients who are in wheelchairs with brakes locked and footrests swung away; for clients who are in sturdy, straight armchairs positioned with the back against the wall; and for clients who cannot stand independently:

1. Position trousers on legs as in method I, steps 1 through 5.
2. Elevate hips by leaning back against chair and pushing down against the floor with stronger leg. As hips are raised, work trousers over hips with stronger hand.
3. Lower hips back into chair and fasten trousers.

Removing Trousers

1. Unfasten trousers and work down on hips as far as possible while sitting.
2. Lean back against chair, push down against floor with stronger leg to elevate hips, and with stronger arm work trousers down past hips.
3. Proceed as in method I, steps 3 and 4.

Method III

Donning Trousers Method III is for clients who are in a recumbent position. It is more difficult to perform than those methods done while sitting. If possible, the bed should be raised to a semireclining position for partial sitting:

1. Using stronger hand, place affected leg in bent position and cross over stronger leg, which may be partially bent to prevent affected leg from slipping.
2. Position trousers and work onto affected leg first, up to the knee. Then uncross leg.
3. Insert stronger leg and work trousers up onto hips as far as possible.
4. With stronger leg bent, press down with foot and shoulder to elevate hips from bed. With stronger arm, pull trousers over hips or work trousers up over hips by rolling from side to side.
5. Fasten trousers.

Removing Trousers

1. Hike hips by bridging as in putting trousers on in method III, step 4.
2. Work trousers down past hips by rolling side to side; remove pants from unaffected leg and then affected leg.

Brassiere

Donning Brassiere

1. Tuck one end of brassiere into pants, girdle, or skirt waistband and wrap other end around waist (wrapping toward affected side may be easiest). Hook brassiere in front at waist level and slip fastener around to back (at waistline level).
2. Place affected arm through shoulder strap, and then place stronger arm through other strap.
3. Work straps up over shoulders. Pull strap on affected side up over shoulder with stronger arm. Put stronger arm through its strap and work up over shoulder by directing arm up and out and pulling with hand.
4. Use stronger hand to adjust breasts in brassiere cups.

Note: It is helpful if the brassiere has elastic straps and is made of stretch fabric. If there is some function in the affected hand, a fabric loop may be sewn to the back of the brassiere near the fastener. The affected thumb may be slipped through the loop to stabilize the brassiere while the stronger hand fastens it. All elastic brassieres, prefastened or without fasteners, may be put on by adapting method I for pullover shirts described previously. Front-opening bras may also be adapted with a loop for the affected hand with some gross arm function.

Removing Brassiere

1. Slip straps down off shoulders, stronger side first.
2. Work straps down over arms and off hands.
3. Slip brassiere around to front with stronger arm.
4. Unfasten and remove.

Necktie

Donning Necktie

Clip-on neckties are convenient. If a conventional tie is used, the following method is recommended:

1. Place collar of shirt in “up” position and bring necktie around neck and adjust so that smaller end is at desired length when tie is completed.
2. Fasten small end to shirt front with tie clasp or spring clip clothespin.
3. Loop long end around short end (one complete loop), and bring up between “V” at neck. Then bring tip down through loop at front and adjust tie, using ring and little fingers to hold tie end, and thumb and forefingers to slide knot up tightly.

Removing Necktie

Pull knot at front of neck until small end slips up enough for tie to be slipped over head. Tie may be hung up in this state and replaced by slipping it over head around upturned collar and knot tightened as described in step 3 of the donning phase.

Socks or Stockings**Donning Socks or Stockings**

1. Sit in straight armchair or in wheelchair with brakes locked, feet on the floor, and footrest swung away.
2. With stronger leg directly in front of midline of body, cross affected leg over stronger leg.
3. Open top of stocking by inserting thumb and first two fingers near cuff and spreading fingers apart.
4. Work stocking onto foot before pulling over heel. Care should be taken to eliminate wrinkles.
5. Work stocking up over leg. Shift weight from side to side to adjust stocking around thigh.
6. Thigh-high stockings with an elastic band at the top are often an acceptable substitute for panty hose, especially for the nonambulatory individual.
7. Panty hose may be donned and doffed as a pair of slacks, except that the legs would be gathered up one at a time before placing feet into the leg holes.

Removing Socks or Stockings

1. Work socks or stockings down as far as possible with stronger arm.
2. Cross affected leg over stronger one as described in step 2 of process of putting on socks or stockings.
3. Remove sock or stocking from affected leg. Dressing stick may be required by some clients to push sock or stocking off heel and off foot.
4. Lift stronger leg to comfortable height or to seat level and remove sock or stocking from foot.

Shoes

If possible, select slip-on shoes to eliminate lacing and tying. If an individual uses an ankle-foot orthosis (AFO) or short leg brace, shoes with fasteners are usually needed:

1. Use elastic laces and leave shoes tied.
2. Use adapted shoe fasteners.
3. Use one-handed shoe-tying techniques (Figure 10-27).
4. It is possible to learn to tie a standard bow with one hand, but this requires excellent visual, perceptual, and motor planning skills along with much repetition.

Ankle-Foot Orthosis

The individual with hemiplegia who lacks adequate ankle dorsiflexion to walk safely and efficiently frequently uses an AFO. The following is one technique that may be used.

FIGURE 10-27 One-hand shoe-tying method.

(Courtesy Christine Shaw, Metro Health Center for Rehabilitation, Metro Health Medical Center, Cleveland, Ohio.)

Donning an AFO**Method I**

1. Sit in straight armchair or wheelchair with brakes locked and feet on the floor (Figure 10-28, A). The fasteners are loosened and the tongue of the shoe is pulled back to allow the AFO to fit into the shoe (Figure 10-28, B).
2. AFO and shoe are placed on the floor between the legs but closer to the affected leg, facing up (Figure 10-28, C).
3. With the unaffected hand, lift the affected leg behind the knee and place toes into the shoe (Figure 10-28, D).
4. Reach down with unaffected hand and lift AFO by the upright. Simultaneously use the unaffected foot against the affected heel to keep the shoe and AFO together (Figure 10-28, E).
5. The heel will not be pushed into the shoe at this point. With the unaffected hand, apply pressure directly downward on the affected knee to push the heel into the shoe, if leg strength is not sufficient (Figure 10-28, F).
6. Fasten Velcro calf strap and fasten shoes (Figure 10-28, G). The affected leg may be placed on a footstool to assist with reaching shoe fasteners.
7. To fasten shoes, one-handed bow tying may be used; elastic shoelaces, Velcro-fastened shoes, or other commercially available shoe fasteners may be required if the client is unable to tie shoes.

Method II Steps 1 and 2 are the same as the positioning required for donning pants.

1. Sit in sturdy armchair or in locked wheelchair.
2. Position stronger leg in front of midline of body with knee flexed to 90 degrees. Using stronger hand, reach forward and grasp ankle of affected leg or sock around ankle. Lift affected leg over stronger leg to crossed position.

FIGURE 10-28 Steps in donning ankle-foot orthosis (AFO).

3. The fasteners are loosened and the tongue of the shoe is pulled back to allow the AFO to fit into the shoe; Velcro fastener on AFO is unfastened.
4. Using stronger hand, hold heel of shoe and work over toes of affected foot and leg. Once toes are in shoe, work top part of AFO around the calf.
5. Pull heel of shoe onto foot with hand or place foot on floor, place pressure on knee, and push heel down into shoe.
6. Fasten Velcro calf strap and fasten shoes.

Removing an AFO

Variation I

1. While seated as for donning an AFO, cross affected leg over stronger leg.
2. Unfasten straps and laces with stronger hand.
3. Push down on AFO upright until shoe is off foot.

Variation II

1. Unfasten straps and laces.
2. Straighten affected leg by putting stronger foot behind heel of shoe and pushing affected leg forward.
3. Push down on AFO upright with hand and at same time push forward on heel of AFO shoe with stronger foot.

Feeding Activities

A primary problem encountered by an individual with only one functional hand is the inability or difficulty using one hand to stabilize an object while using that same hand to perform another task. An example in feeding is a person with one functional hand trying to cut food such as meat using a knife while stabilizing the food at the same time. This problem can be resolved by the use of a rocker knife for cutting meat and other foods (Figure 10-29). This knife cuts with a rocking motion rather than a back-and-forth slicing action. Use of a rocking motion with a standard table knife or a sharp paring knife may be adequate to cut tender meats and soft foods. If such a knife is used, the client is taught to hold the knife handle between the thumb and the third, fourth, and fifth fingers, and the index finger is extended along the top of the knife blade. The knife point is placed in the food in a vertical position, and then the blade is brought down to cut the food. The rocking motion, using wrist flexion and extension, is continued until the food is cut. To stabilize a plate or bowl, a product such as foam-padded shelf liner can be used under it to stabilize it. There are many other adaptive devices such as a plate guard (see Figure 10-20) that the person who eats with only one fully functional hand can utilize. Another feeding issue that

FIGURE 10-29 Rocker knife.
(Courtesy Patterson Medical.)

may arise for the individual is opening packages and containers such as margarine containers and milk cartons while dining. These tasks require practice and should occur with incorporation of the less functional hand in the task if appropriate.

Personal Hygiene and Grooming Activities

Clients with the use of one hand or one side of the body can accomplish personal hygiene and grooming activities by using assistive devices and alternative methods. The following are suggestions for achieving hygiene and grooming with one hand:

1. Use an electric razor rather than a safety razor.
2. Use a shower seat in the shower stall or a transfer tub bench in a bathtub-shower combination. Also use a bath mat, a wash mitt, a long-handled bath sponge, safety rails on the bathtub or wall, soap on a rope or a suction soap holder, and a suction brush for fingernail care.
3. Sponge bathe while sitting at the lavatory using the wash mitt, suction brush, and suction soap holder. The uninvolved forearm and hand may be washed by placing a soaped washcloth on the thigh and rubbing the hand and forearm on the cloth.
4. Use a wall-mounted hair dryer. This device frees the unaffected upper extremity to hold a brush or comb to style the hair during blow-drying.¹²
5. Care for fingernails as described previously for clients with incoordination.
6. Use a suction denture brush for care of dentures. The suction fingernail brush may also serve this purpose (see Figure 10-22).

Toileting

Clients with the use of one hand or one side of the body can accomplish toileting activities by using assistive devices and alternative methods. The following are suggestions for achieving independent and safe toileting with one hand:

1. Use bedside commode with or without drop arms if unable to get to bathroom quickly or safely (Figure 10-30).
2. Use urinal instead of transferring to toilet. Female- and male-designed urinals are available, but the female urinals are not always effective depending on the client's body size.
3. Grab bars strategically placed.
4. Toilet paper placed on unaffected side.

Communication and Environmental Hardware Adaptations

1. The primary problem with writing is stabilization of the paper or tablet. This problem can be overcome by using a clipboard, paperweight, or nonskid surface such as Dycem, or by taping the paper to the writing

FIGURE 10-30 Drop-arm commode.
(Courtesy North Coast Medical.)

surface. In some instances, the affected arm may be positioned on the tabletop to stabilize the paper.

2. If dominance must be shifted to the nondominant extremity, writing practice may be necessary to improve speed and coordination. One-handed writing and keyboarding instruction manuals are available.
3. Book holders may be used to stabilize a book while reading or holding copy for typing and writing practice. A soft pillow placed on one's lap will easily stabilize a book while the person is seated in an easy chair. Clients who enjoy reading as an occupation may want to consider an electronic book reader, such as the Kindle, which allows touch page turning as well as options to enlarge the reading font to the reader's preference.
4. Dialing numbers on a telephone with one hand requires several motions including lifting the receiver to listen for the dial tone, setting it down, pressing the keys, and lifting the receiver to the ear. To write while using the telephone, a stand or shoulder telephone receiver holder can be used. A speakerphone or headset can also leave hands free to take messages. One-touch dialing using preprogrammed phone numbers eliminates pressing as many keys, simplifies sequencing, and may help compensate for memory deficits.

FIGURE 10-31 Zim jar opener.

Functional Mobility

Principles of transfer techniques for clients with hemiplegia are described in Chapter 11.

Home Management, Meal Preparation, and Cleanup Activities

Many assistive devices are available to facilitate home management and meal activities. Various factors determine how many home management and meal activities can realistically be performed, which methods can be used, and how many assistive devices can be managed. These factors include (1) whether the client is disabled by the loss of function of one arm and hand, as in amputation or a peripheral neuropathic condition, or (2) whether both arm and leg are affected along with possible visual, perceptual, and cognitive dysfunctions, as in hemiplegia. The references listed at the end of this chapter provide details of home-making with one hand. The following are some suggestions for home management and meal activities for the client with the use of one hand:¹⁷

1. Stabilizing items is a major problem for the one-handed homemaker. Stabilize foods for cutting and peeling by using a cutting board with two stainless steel or aluminum nails in it. A raised corner on the board stabilizes bread for making sandwiches or spreading butter. Suction cups or a rubber mat under the board will keep it from slipping. A nonskid surface or rubber feet may be glued to the bottom of the board.
2. Use sponge cloths, nonskid mats or pads, wet dishcloths, or suction devices to keep pots, bowls, and dishes from turning or sliding during food preparation.
3. To open a jar, stabilize it between the knees or in a partially opened drawer while leaning against the drawer. Break the air seal by sliding a pop bottle opener under the lid until the air is released, then use a Zim jar opener (Figure 10-31).

4. Open boxes, sealed paper, and plastic bags by stabilizing between the knees or in a drawer as just described, and cut open with household shears. Special box and bag openers are also available from ADL equipment vendors.
5. Crack an egg by holding it firmly in the palm of the hand. Hit it in the center against the edge of the bowl. Then using the thumb and index finger, push the top half of the shell up and use the ring and little finger to push the lower half down. Separate whites from yolks by using an egg separator, funnel, or large slotted spoon.
6. Eliminate the need to stabilize the standard grater by using a grater with suction feet, or use an electric countertop food processor instead.
7. Stabilize pots on the counter or range for mixing or stirring by using a pan holder with suction feet (Figure 10-32).
8. Eliminate the need to use hand-cranked or electric can openers, which necessitate the use of two hands, by using a one-handed electric can opener.
9. Use a utility cart to carry items from one place to another. For some clients, a cart that is weighted or constructed of wood may be used as a minimal support during ambulation.
10. Transfer clothes to and from the washer or dryer by using a clothes carrier on wheels.
11. Use electrical appliances—such as a lightweight electrical hand mixer, emersion blender wand, blender, and food processor—that can be managed with one hand and save time and energy. Safety factors and judgment need to be evaluated carefully when electrical appliances are considered.
12. Floor care becomes a greater problem if, in addition to one arm, ambulation and balance are affected. For clients with involvement of only one arm, a standard dust mop, carpet sweeper, or upright vacuum cleaner

should present no problem. A self-wringing mop may be used if the mop handle is stabilized under the arm and the wringing lever operated with the stronger arm. Clients with balance and ambulation problems may manage some floor care from a sitting position. Dust mopping or using a carpet sweeper may be possible if gait and balance are fairly good without the aid of a cane. Some people may benefit from a programmable robotic vacuum cleaner such as the ROOMBA from iRobot (<http://store.irobot.com/home/index.jsp>). However, careful consideration must be made, as the device can also be a safety/tripping hazard if for some reason it does not return to its docking station.

These are just a few of the possibilities for solving homemaking problems for one-handed individuals. The occupational therapist must evaluate each client to determine how the dysfunction affects the performance of homemaking activities. One-handed techniques take more time and may be difficult for some clients to master. Activities should be paced to accommodate the client's physical endurance and tolerance for one-handed performance and use of special devices. Work simplification and energy conservation techniques should be employed. New techniques and devices should be introduced on a graded basis as the client masters first one technique and device and then another. Family members need to be oriented to the client's skills, special methods used, and work schedule. The therapist, with the family and client, may facilitate the planning of homemaking responsibilities to be shared by other family members and the supervision of the client, if that is needed. If special equipment and assistive devices are needed for ADL, it is advisable for the client to practice using the devices in the clinic if possible. The therapist can then train the client and demonstrate use of the equipment to a family member before these items are purchased and used at home. After training, the occupational therapist should provide the client with sources to replace items independently, such as a consumer catalog of adaptive equipment.

FIGURE 10-32 Pan stabilizer.

ADLs for the Person with Paraplegia

Clients who must use a wheelchair for mobility need to find ways to perform ADLs from a seated position, to transport objects, and to adapt to an environment designed for standing and walking. Given normal function in the upper extremities and otherwise good health, the wheelchair user can probably perform ADL independently. The client should have a stable spine or use an appropriate orthotic or stabilization device, and the physician should clearly identify mobility precautions.

Dressing Activities¹

It is recommended that clients who must use wheelchairs put on clothing in this order: stockings, undergarments, braces (if worn), slacks, shoes, shirt or dress. Underwear

may be eliminated as it is an extra step, has the potential to contribute to skin breakdown, and results in greater difficulty when toileting. During initial rehabilitation the person with paraplegia will likely begin dressing training in bed, and as strength, endurance, and balance improve, the patient will progress to dressing in the wheelchair. The ability to dress in the wheelchair will simplify toileting by eliminating the need to go back to bed to manage clothing.

Slacks

Donning Slacks

Slacks are easier to fasten if they button or zip in front. If braces are worn, zippers in side seams may be helpful. Wide-bottom slacks of stretch fabric are recommended. The procedure for putting on shorts, slacks, and underwear is as follows:

1. Use side rails or a trapeze to pull up to sitting position, back supported with pillows or headboard of the bed.
2. Sit on bed and reach forward to feet, or sit on bed and pull knees into flexed position.
3. Holding top of pants, flip pant leg down to feet.
4. Work pant legs over feet and pull up to hips. Crossing ankles may help get pants on over heels.
5. In a semireclining position, roll from hip to hip and pull up garment.
6. A long-handled reacher may be helpful for pulling garment up or positioning garment on feet if there is impaired balance or range of motion in the lower extremities or trunk.

Removing Slacks

Remove pants or underwear by reversing the procedure for putting them on. Dressing sticks may be helpful for pushing pants off feet.

Socks or Stockings

Soft stretch socks or stockings are recommended. Pantyhose that are slightly large may be useful. Elastic garters or stockings with elastic tops should be avoided because of potential skin breakdown. Dressing sticks or a stocking device may be helpful to some clients.

Donning Socks or Stockings

1. Put on socks or stockings while seated (long sitting) on bed.
2. Pull one leg into flexion with one hand and cross over the other leg.
3. Use other hand to slip sock or stocking over foot and pull sock or stocking on.

Removing Socks or Stockings

Remove socks or stockings by flexing leg as described for donning, pushing sock or stocking down over heel. Make sure any wrinkles or creases are removed from socks to

prevent pressure skin breakdown. Dressing sticks may be needed to push sock or stocking off heel and toe and to retrieve sock.

Slips and Skirts

Slips and skirts slightly larger than usually worn are recommended. A-line, wraparound, and full skirts are easier to manage and look better on a person seated in a wheelchair than narrow skirts.

Donning Slips and Skirts

1. Sit on bed, slip garment over head, and let it drop to waist.
2. In semireclining position, roll from hip to hip and pull garment down over hips and thighs.

Removing Slips and Skirts

1. In sitting or semireclining position, unfasten garment.
2. Roll from hip to hip, pulling garment up to waist level.
3. Pull garment off over head.

Shirts

Fabrics should be wrinkle-resistant, smooth, and durable. Roomy sleeves and backs and full shirts are more suitable styles than closely fitted garments.

Donning Shirts

Shirts, pajama jackets, robes, and dresses that open completely down the front may be put on while the client is seated in a wheelchair. If it is necessary to dress while in bed, the following procedure can be used:

1. Balance body by putting palms of hands on mattress on either side of body. If balance is poor, assistance may be needed or bed backrest/head of bed may be elevated. (If backrest cannot be elevated, one or two pillows may be used to support back.) With backrest elevated, both hands are available.
2. If difficulty is encountered in customary methods of applying garment, open garment on lap with collar toward chest. Put arms into sleeves and pull up over elbows. Then hold on to shirt tail or back of dress, pull garment over head, adjust, and button.

Removing Shirts

1. Sitting in wheelchair or bed, open fastener.
2. Remove garment in the usual manner.
3. If the usual manner is not feasible, grasp collar with one hand while balancing with other hand. Gather material up from collar to hem.
4. Lean forward, duck head, and pull shirt over head.
5. Remove sleeves, first from supporting arm and then from working arm.

Shoes**Donning Shoes**

If an individual has sensory loss and is at risk for bruising during transfers, shoes should be donned in bed.

Variation I

1. In sitting position on bed, edge of bed, or in wheelchair for back support, pull one knee at a time into flexed position with hands.
2. While supporting leg in flexed position with one hand, use free hand to put on shoe.

Variation II

1. Sit on edge of bed or in wheelchair for back support.
2. Cross one leg over the other and slip shoe onto foot.
3. Put foot on footrest and push down on knee to push foot into shoe.

Removing Shoes

1. Flex or cross leg as described for appropriate variation.
2. For variation I, remove shoe with one hand while supporting flexed leg with other hand.
3. For variation II, remove shoe from crossed leg with one hand while maintaining balance with other hand, if necessary.

Feeding Activities

Eating activities should present no special problem for the person who uses a wheelchair but has good to normal arm function. Wheelchairs with desk-style armrests and footrests that fit under tabletops are recommended so that it is possible to sit close to the table. Footrests on the wheelchair may be detachable or fixed but need to function within the client's environment for maximum independence.

Personal Hygiene and Grooming

Facial and oral hygiene and arm and upper body care should present no problem. Reachers may be helpful for securing towels, washcloths, makeup, deodorant, and shaving supplies from storage areas, if necessary. Special equipment is needed for using tub baths or showers. Transfer techniques for toilet and bathtub are discussed in [Chapter 11](#). The following are suggestions for facilitating safety and independence during bathing activities:

1. Use a handheld shower hose and keep a finger over the spray to determine sudden temperature changes in water. Make sure water heater is set at a safe temperature (120° Fahrenheit, 49° Celsius) to prevent scald burns.⁴¹
2. Use long-handled bath brushes with soap insert for ease in reaching all parts of the body.
3. Use soap bars attached to a cord around the neck, or use liquid soap.

4. Use padded shower chair or padded transfer tub bench. Consider commode cutout if bowel program is performed in the shower.
5. Increase safety during transfers by installing grab bars on wall near bathtub or shower and on bathtub to provide balance point when during transfers and when bending to wash legs and buttocks.
6. Fit bathtub or shower bottom with nonskid mat or adhesive material.
7. Remove doors on the bathtub and replace with a shower curtain to increase safety and ease of transfers.

Skin Integrity and Hygiene

Because sensory loss increases the risk of skin breakdown, regular skin checks and weight shifts should be considered a normal part of the ADL routine. Clients should be instructed in the following:

1. Potential areas on the body for possible skin breakdown, signs of developing skin problems, and ways to maintain good skin integrity.
2. How and when to perform proper weight shifts while up in the wheelchair and how to position oneself in bed to prevent skin breakdown.
3. Frequency of skin checks and how to perform them. The client can use a long-handled mirror ([Figure 10-33](#)) to see areas that are otherwise difficult to observe.
4. Need for maintenance on all equipment to assure disrepair is not contributing to skin breakdown. For example, a tear in a padded tub bench could potentially tear skin on the buttocks, resulting in skin breakdown.

Bowel and Bladder Management

An occupational therapist along with nursing staff may both be involved in instructing the client about digital stimulation or use of intermittent catheterization for elimination. Helping the client to establish a routine for this ADL is also important, as ineffective bowel and bladder management may lead to significant limitations in other activities if the client is experiencing accidents or infections. An occupational therapist may recommend appropriate equipment, help with the establishment of routines, and problem solve as issues arise. An interdisciplinary approach is critical for health maintenance regarding bowel and bladder care:

1. Use padded commode or raised toilet seat.
2. Keep needed items within reach.
3. Develop strategies to manage intermittent catheterizations in public bathrooms, such as using a waist pack to hold items, and establish methods to sanitize hands.

FIGURE 10-33 Long-handled mirror.
(Courtesy North Coast Medical.)

Communication and Environmental Hardware Adaptations

With the exception of reaching difficulties in some situations, use of the telephone should present no problem. Short-handled reachers may be used to grasp the receiver from the cradle. A cordless telephone can eliminate reaching, except when the phone needs recharging. A mobile phone or other smart phones can also be used. The use of writing implements and a personal computer should be possible. Managing doors may present some difficulties. If the door opens toward the person, it can be opened by the following procedure:

1. If doorknob is on the right, approach door from right and turn doorknob with left hand.
2. Open door as far as possible, and move wheelchair close enough so that it helps keep door open.
3. Holding door open with left hand, turn wheelchair with right hand and wheel through door.
4. Start closing door when halfway through.

If the door is very heavy and opens out or away from the person, the following procedure is recommended:

1. Back up to door so knob can be turned with right hand.
2. Open door and back through so that big wheels keep it open.
3. Also use left elbow to keep door open.
4. Wheel backward with right hand.

Functional Mobility

Principles of transfer techniques are discussed in Chapter 11.

Home Management, Meal Preparation, and Cleanup Activities

When homemaking activities are performed from a wheelchair, the major problems are work heights, adequate space for maneuverability, access to storage areas, and transfer of supplies, equipment, and materials from place to place. If funds are available for kitchen remodeling, lowering counters and opening space under counters and range to a comfortable height for wheelchair use is recommended. Such extensive adaptation is often not feasible, however. The following are some suggestions for homemaking activities:¹⁷

1. Remove cabinet doors to eliminate the need to maneuver around them for opening and closing. Frequently used items should be stored toward the front of easy-to-reach cabinets above and below the counter surfaces.
2. If entrance and inside doors are not wide enough, make doors slightly wider by removing strips along the doorjambs. Offset hinges can replace standard door hinges and increase the doorjamb width by 2 inches (Figure 10-34).
3. Use a wheelchair cushion to increase the user's height so that standard height counters may be used.
4. Use detachable desk-style armrests and swing-away detachable footrests to allow the wheelchair user to get as close as possible to counters and tables and also to stand at counters, if that is possible.
5. Transport items safely and easily with a wheelchair lapboard. The lapboard may also serve as a work surface for writing, preparing food, or drying dishes (Figure 10-35). It also protects the lap from injury from hot pans and prevents utensils from falling into the lap. Use silicone pads as nonslip surfaces and to prevent burning.
6. Fasten a drop-leaf board to a bare wall, or install a slide-out board under a counter to provide a work surface that is a comfortable height in a kitchen that is otherwise standard. Place a cutting board on an open drawer to set up a workstation. The drawer should be stable when pulled out and be at a height that allows the wheelchair user to roll under it and reach with a comfortable arm position.

FIGURE 10-34 A, Offset door hinges. B, Offset hinges widen doorway for wheelchair user.
(Courtesy Sammons Preston.)

FIGURE 10-35 Wheelchair with lapboard.
(Courtesy North Coast Medical.)

7. Fit cabinets with custom- or ready-made lazy Susans or pullout shelves to eliminate the need to reach to rear space.
8. Ideally, ranges should be at a lower level than standard height. If this arrangement is not possible,

place the controls at the front of the range, and hang a mirror angled at the proper degree over the range so that the cook can see contents of pots.

9. Substitute small electric toaster oven with a microwave oven, or use microwave convection oven for the range if the range is not safely manageable.
10. Use front-loading washers and dryers. Use a reacher for items that are difficult to reach in the washer and dryer.
11. Vacuum carpets with a carpet sweeper or tank-type cleaner that rolls easily and is lightweight or self-propelled. A retractable cord may prevent the cord from tangling in the wheels.
12. Sweep and mop floors with lightweight swivel head cleaners that allow easier reach.

ADLs for the Person with Quadriplegia/Tetraplegia

To develop an overview of functional outcomes for each level of SCI, refer to [Chapter 36](#), which provides extensive tables relating ADLs and IADLs to specific levels of SCI. Persons with C1-4 will require assist for all ADLs except communication and mobility, if appropriate equipment is available. Levels C5 will require considerable special equipment and assistance. Externally powered splints and arm braces or mobile arm supports are recommended for C3, C4, and C5 levels of muscle function and are discussed in [Chapters 30 and 36](#). Individuals with muscle function from C6 can be relatively independent with adaptations and assistive devices and may benefit from the use of a

wrist-driven flexor hinge hand splint (also known as tenodesis hand splint).

Dressing Activities

Training in dressing can be commenced when the spine is stable.^{7,28} Minimum criteria for upper-extremity dressing are as follows:

1. Fair to good muscle strength in deltoids, upper and middle trapezii, shoulder rotators, rhomboids, biceps, supinators, and radial wrist extensors.
2. ROM of 0 degrees to 90 degrees in shoulder flexion and abduction, 0 degrees to 80 degrees in shoulder internal rotation, 0 degrees to 30 degrees in external rotation, and 15 degrees to 140 degrees in elbow flexion.
3. Sitting balance in bed or wheelchair, which may be achieved with the assistance of bed rails, an electric hospital bed, or a wheelchair safety belt.
4. Finger prehension achieved with adequate tenodesis grasp or wrist-driven flexor-hinge splint.

Additional criteria for dressing the lower extremities are as follows:²⁸

1. Fair to good muscle strength in pectoralis major and minor, serratus anterior, and rhomboid major and minor.
2. ROM of 0 degrees to 120 degrees in knee flexion, 0 degrees to 110 degrees in hip flexion, and 0 degrees to 80 degrees in hip external rotation.
3. Body control for transfer from bed to wheelchair with minimal assistance.
4. Ability to roll from side to side, turn from supine position to prone position and back, and balance in side-lying.
5. Vital capacity must be greater than 50%.¹⁰

Dressing is contraindicated if any of the following factors are present:^{7,28}

1. Unstable spine at site of injury.
2. Pressure sores or tendency for skin breakdown during rolling, scooting, and transferring.
3. Uncontrollable muscle spasms in legs.
4. Less than 50% vital capacity.

Sequence of Dressing

The recommended sequence for training to dress is to put on slacks while still in bed, then transfer to a wheelchair and put on shirts, socks, and shoes.²⁸ Some clients may wish to put the socks on before the pants because socks may help the feet slip through the pant legs more easily.

Expected Proficiency

Clients with spinal cord lesions at C7 and below can achieve independence with dressing for both the upper and lower extremities. Clients with lesions at C6 can also achieve

independence with dressing, but lower-extremity dressing may be difficult or impractical in terms of time and energy for these clients. Clients with lesions at C5 to C6 can achieve upper-extremity dressing, with some exceptions. It is difficult or impossible for these clients to put on a bra, tuck a shirt or blouse into a waistband, or fasten buttons on shirt fronts and cuffs. Factors such as age, physical proportions, coordination, secondary medical conditions, and motivation will affect the degree of proficiency in dressing skills that any client can achieve.⁷ McBearson demonstrated how to dress with his abilities with C6 quadriplegia.³¹

Types of Clothing

Clothing should be loose and have front openings. Slacks need to be a size larger than usually worn to accommodate the urine collection device or leg braces if worn. Wrap-around skirts and incontinence pads are helpful for women. The fasteners that are easiest to manage are zippers and Velcro closures. Because the client with quadriplegia often uses the thumb as a hook to manage clothing, loops attached to zipper pulls, undershorts, and even the back of the shoes can be helpful. Belt loops on slacks are used for pulling and should be reinforced. Bras should have stretch straps and no wires in them. Front-opening bra styles can be adapted by fastening loops and adding Velcro closures; back-opening styles can have loops added at each side of the fastening. Underwear may be eliminated as it is an extra step, has the potential to contribute to skin breakdown, and results in greater difficulty when toileting.

Shoes can be one-half size to one size larger than normally worn to accommodate edema and spasticity and to avoid pressure sores. Shoe fasteners can be adapted with Velcro, elastic shoelaces, large buckles, or flip-back tongue closures. Loose woolen or cotton socks without elastic cuffs should be used initially. Nylon socks, which tend to stick to the skin, may be used as skill is gained. If neckties are used, the clip-on type or a regular tie that has been preknotted and can be slipped over the head may be manageable for some clients.^{7,28}

Slacks

Donning Slacks, SCI Level C6-7

1. Long sit on bed with bed rails up. Slacks are positioned at foot of bed with pant legs over end of bed and front side up.²⁸
2. Sit up and lift one knee at a time by hooking right hand under right knee to pull leg into flexion, then put pants over right foot. Return right leg to extension or semiextended position while repeating procedure with left hand and left knee.⁷ If unable to maintain leg in flexion by holding with one arm or through advantageous use of spasticity, use a dressing band. This device is a piece of elasticized webbing that has been sewn into a figure-eight pattern, with one small loop and one large loop. The small loop is hooked around the foot and the large hoop is

anchored over the knee. The band is measured for the individual client so that its length is appropriate to maintain desired amount of knee flexion. Once slacks are in place, knee loop is pushed off knee and dressing band is removed from foot with dressing stick.

3. Work slacks up legs, using patting and sliding motions with palms of hands.
4. While still sitting, with pants to midcalf height, insert dressing stick in front belt loop. Dressing stick is gripped by slipping its loop over wrist. Pull on dressing stick while extending trunk, returning to supine position. Return to sitting position and repeat this procedure, pulling on dressing sticks and maneuvering slacks up to thigh level.²⁸ If balance is adequate, an alternative is for client to remain seated, lean on left elbow, and pull slacks over right buttock, then reverse process for other side. Another alternative is for client to remain in supine position and roll to one side; throw opposite arm behind back; hook thumb in waistband, belt loop, or pocket; and pull slacks up over hips. These maneuvers can be repeated as often as necessary to get slacks over buttocks.⁷
5. Using palms of hands in pushing and smoothing motions, straighten the slack legs.
6. In supine position, fasten slacks by hooking thumb in loop on zipper pull, patting Velcro closed or using hand splints and buttonhooks if there are buttons or a zipper pull for zippers.^{7,28}

Variation Substitute the following for step 2: Sit up and lift one knee at a time by hooking right hand under right knee to pull leg into flexion, then cross the foot over the opposite leg above the knee. This position frees the foot to place the slacks more easily and requires less trunk balance. Continue with all other steps.

Removing Slacks, SCI Level C6-7

1. Lying supine in bed with bed rails up, unfasten belt and fasteners.
2. Placing thumbs in belt loops, waistband, or pockets, work slacks past hips by stabilizing arms in shoulder extension and scooting body toward head of bed.
3. Use arms as described in step 2 and roll from side to side to get slacks past buttocks.
4. Coming to sitting position and alternately pulling legs into flexion, push slacks down legs.²⁸
5. Slacks can be pushed off over feet with dressing stick or by hooking thumbs in waistband.

Front Opening or Pullover Garments, SCI Level C5-7

Front opening and pullover garments include blouses, jackets, vests, sweaters, skirts, and front-opening dresses.^{7,28} Upper-extremity dressing is frequently performed in the

wheelchair for greater trunk stability. The procedure for putting on these garments is as follows.

Donning Front Opening or Pullover Garments, SCI Level C5-7

1. Position the garment across thighs with back facing up and neck toward knees.
2. Place both arms under back of garment and in armholes.
3. Push sleeves up onto arms, past elbows.
4. Using a wrist extension grip, hook thumbs under garment back and gather material up from neck to hem.
5. To pass garment over head, adduct and externally rotate shoulders and flex elbows while flexing head forward.
6. When garment is over head, relax shoulders and wrists and remove hands from back of garment. Most of material will be gathered up at neck, across shoulders, and under arms.
7. To work garment down over body, shrug shoulders, lean forward, and use elbow flexion and wrist extension. Use wheelchair arms for balance, if necessary. Additional maneuvers to accomplish this task are to hook wrists into sleeves and pull material free from underarms, or lean forward, reach back, and slide hand against material to aid in pulling garment down.
8. Garment can be buttoned from bottom to top with aid of buttonhook and wrist-driven flexor hinge splint if hand function is inadequate.

Removing Front Opening or Pullover Garments, SCI Level C5-7

1. Sit in wheelchair and wear wrist-driven flexor hinge splints. Unfasten buttons (if any) while wearing splints and using buttonhook. Remove splints for remaining steps.
2. For pullover garments, hook thumb in back of neckline, extend wrist, and pull garment over head while turning head toward side of raised arm. Maintain balance by resting against opposite wheelchair armrest or pushing on thigh with extended arm.
3. For stretchy front opening style clothing, hook thumb in opposite armhole and push sleeve down arm. Elevation and depression of shoulders with trunk rotation can be used to get garment to slip down arms as far as possible.
4. Hold one cuff with opposite thumb while elbow is flexed to pull arm out of sleeve.

Bra (Back-Opening)

Donning Bra, SCI Level C5-7

When worn, this bra style fastens at the back with a hook and eye. The bra is adapted and has loop extenders attached on both the right and left side of fasteners. Procedurally, the

bra is attached in front first around the body, then twisted around into position. Arms are placed in strap last. Here are the step-by-step directions:

1. Place bra across lap with straps toward knees and inside facing up.
2. Using a right-to-left procedure, hold end of bra closest to right side with hand or reacher and pass bra around back from right to left side. Lean against bra at back to hold it in place while hooking thumb of left hand in a loop that has been attached near bra fastener. Hook right thumb in a similar loop on right side, and fasten bra in front at waist level.
3. Hook right thumb in edge of bra. Using wrist extension, elbow flexion, shoulder adduction, and internal rotation, rotate bra around body so that front of bra is in front of body.
4. While leaning on one forearm, hook opposite thumb in front end of strap and pull strap over shoulder, then repeat procedure on other side.^{7,28}

Removing Bra

1. Hook thumb under opposite bra strap and push down over shoulder while elevating shoulder.
2. Pull arm out of strap and repeat the procedure for other arm.
3. Push bra down to waist level and turn around as described previously to bring fasteners to front.
4. Unfasten bra by hooking thumbs into the adapted loops near the fasteners.

Alternatives for a back-opening bra are (1) a front-opening bra with loops for using a wrist extension grip or (2) a fully elastic bra that has no fasteners, such as a sports bra, and can be donned like a pullover sweater.

Socks

Donning Socks, SCI Level C6-7

Method I

1. Sit in wheelchair, or on bed if balance is adequate, in cross-legged position with one ankle crossed over opposite knee.
2. Pull sock over foot using wrist extension and patting movements with palm of hand.^{7,28} To prevent pressure areas, check to make sure there are no creases or thickened areas on socks.

Method II

1. Sitting in a wheelchair with seat belt fastened, hook one arm at the elbow around the wheelchair upright. This allows for improved stability while reaching.
2. Position foot on stool, chair, or open drawer to elevate the foot easily enough to reach.
3. Pull sock over foot using wrist extension and patting movements with palm of hand.^{7,28} To prevent pressure

areas, check to make sure there are no creases or thickened areas on socks.

Method III

1. Use stocking aid or sock cone (see Figure 10-8) to assist in putting on socks while in this position. Powder sock cone (to reduce friction) and apply sock to cone by using thumbs and palms of hands to smooth sock out on cone.
2. With the cord loops of sock cone around the wrist or thumb, throw cone beyond foot.
3. Maneuver cone over toes by pulling cords using elbow flexion. Insert foot as far as possible into cone.
4. To remove cone from sock after foot has been inserted, move heel forward off wheelchair footrest. Use wrist extension (of hand not operating sock cone) behind knee and continue pulling cords of cone until it is removed and sock is in place on foot. Use palms to smooth sock with patting and stroking motion.²⁸
5. Two loops can also be sewn on either side of the top of the sock so that thumbs can be hooked into the loops and the socks pulled on.

Removing Socks, SCI Level C6-7

Method I

1. While sitting in wheelchair or long sitting in bed and hips flexed forward, use a dressing stick or long-handled shoehorn to push sock down over heel. Cross the legs if possible. If adaptive device is not used, hook thumb in socks and use wrist extension to slide socks off.
2. To protect skin, use dressing stick with coated end to push sock off toes.

Method II

1. While long sitting in bed and hips flexed forward, slide hands into socks with wrist extended gradually working sock off of feet and toes.

Shoes

Donning Shoes, SCI Level C6-7

1. Use same position for donning socks as for putting on shoes.
2. Use long-handled dressing stick and insert aid into tongue of shoe. Place shoe opening over toes. Remove dressing aid from shoe and dangle shoe on toes.
3. Using palm of hand on sole of shoe, pull shoe toward heel of foot. One hand is used to stabilize leg while other hand pushes against sole of shoe to work shoe onto foot. Use palms and sides of hand to push shoe on.
4. With feet flat on floor or on wheelchair footrest and knees flexed 90 degrees, place a long-handled shoehorn in heel of shoe and press down on top of flexed knee until heel is in the shoe.
5. Fasten shoes.²⁸

Removing Shoes, SCI Level C6-7

1. Sitting in wheelchair with legs crossed as described previously, unfasten shoes.
2. Use shoehorn or dressing stick to push on heel counter of shoe, dislodging it from heel. Shoe will drop or can be pushed to floor with dressing stick.²⁸

Feeding Activities

Feeding may be assisted by a variety of devices, depending on the level of the client's muscle function.¹ Someone with an injury from C1-4 will likely need assistance to eat unless an electrical self-feeding device is used. These devices allow independence once set up by using head movement to hit a switch that turns the plate and brings the spoon down to the plate and back up to mouth level.

An injury at C5 may require mobile arm supports or externally powered splints and braces. A wrist splint and universal cuff may be used together if a wrist-driven flexor hinge splint is not used. The universal cuff holds the eating utensil, and the splint stabilizes the wrist. A nonskid mat and a plate with a plate guard may adequately stabilize the plate for pushing and picking up food (C5-7) (see Figure 10-12).

A regular or swivel spoon-fork combination with a universal cuff can be used when there is minimal muscle function (C5). A long plastic straw with a straw clip to stabilize it in the cup or glass eliminates the need for picking up the cups. A bilateral or unilateral clip-type holder on a glass or cup makes it possible for many persons with hand and arm weakness to manage liquids without a straw.

Built-up utensils may be useful for those with some functional grasp or tenodesis grasp. Food may be cut with an adapted knife if arm strength is adequate to manage the device. Food may also be cut using a sharp knife if a wrist-driven flexor hinge splint is used.

Personal Hygiene and Grooming

1. Use a padded shower seat or padded transfer tub bench and transfer board for transfers (SCI Level C1-7).
2. Extend reach by using long-handled bath sponges with loop handle or built-up handle (SCI Level C6-7).
3. Eliminate need to grasp washcloth by using bath mitts or bath gloves (SCI Level C5-7).
4. Hold comb and toothbrush with a universal cuff² (SCI Level C5-7).
5. Use a wall-mounted hair dryer. Use a universal cuff to hold brush or comb for hair styling while using this mounted hair dryer¹⁰ (SCI Level C5-7) (Figure 10-36).
6. Use a clip-type holder for electric razor (SCI Level C5-7).
7. Persons with quadriplegia can use suppository inserters to manage bowel care independently (SCI Level C6-7).

FIGURE 10-36 Hair dryer holder.

(Courtesy Patterson Medical.)

8. Use skin inspection mirror with long stem and looped handle for independent skin inspection (see Figure 10-33). Devices and methods selected must be adapted according to the degree of weakness of each client (SCI Level C6-7).
9. Adapted leg-bag clamps to empty catheter leg-bags are also available for individuals with limited hand function. Elastic leg-bag straps may also be replaced with Velcro straps (SCI Level C5-7).
10. If the client is unable to reach the leg back clamp, a commercially available electric leg bag clamp allows the individual to drive up to a urinal and empty the leg bag with the switch of a button (Richardson Products) (SCI Level C1-7).

Communication and Environmental Hardware Adaptations

1. Turn pages with an electric page-turner, mouth stick, or head wand if hand and arm function are inadequate (Figure 10-37) (SCI Level C4-5).
2. For keyboarding, writing, and painting, insert pen, pencil, typing stick, or paintbrush in a universal cuff that has been positioned with the opening on the ulnar side of the palm (Figure 10-38) (SCI Level C5-7).
3. Touch telephone keys with the universal cuff and a pencil positioned with eraser down (SCI Level C5-7). The receiver may need to be positioned for listening. For clients with no arm function, a speakerphone can be used along with a mouth stick to push the button to initiate a call. Set for speed-dial any frequently used numbers. An operator can also assist with dialing (SCI Level C1-C5).

FIGURE 10-37 Mouth wand.
(Courtesy Patterson Medical.)

FIGURE 10-38 Typing with keyboard aid.
(Courtesy Patterson Medical.)

4. Mobile phones allow many functions with voice activation including, calling out, automatic answering that goes to an ear piece, music functions, web searches, calendar programs, contact directories, and global positioning systems (GPSs). A touch-screen phone with multiple functions can eliminate the need for multiple devices to organize information (SCI Level C1-C7).
5. Use personal computers or personal digital assistants (PDAs). A computer mouse or voice-recognition program may be substituted for use of the keyboard. A variety of different mouse and keyboard designs, and sizes, are available (SCI Level C1-7).
6. Clients with hand weakness can use built-up pencils and pens or special pencil holders. The Wanchik

writer is an effective adaptive writing device (see Figure 10-16) (SCI Level C5-7).

7. Sophisticated electronic communications devices operated by mouth, pneumatic controls, and head controls are available for clients with no function in the upper extremities. Other communication devices are available that rely on eye blinks and gazes (SCI Level C1-5).
8. MP3 (a digital audio recording format) players are capable of playing digitally available music and podcasts and can be used with universal cuff and a pencil positioned with eraser down or other adapted pointer to press buttons (SCI Level C5-7).
9. Environmental controls allow for easy operation from a panel designed to run multiple devices such as televisions, radios, lights, telephones, intercoms, and hospital beds (see Chapter 17) (SCI Level C1-7).

Functional Mobility

Principles of wheelchair transfer techniques for the individual with quadriplegia are discussed in Chapter 11. Mobility depends on degree of weakness. Electric wheelchairs operated by hand, chin, head, or pneumatic controls have greatly increased the mobility of persons with severe upper- and lower-extremity weakness. Vans fitted with wheelchair lifts and stabilizing devices permit these clients to be transported to pursue community, vocational, educational, and leisure activities with an assistant. In addition, adaptations for hand controls have made it possible for many clients with function of at least C6 level to drive independently.

Home Management, Meal Preparation, and Cleanup Activities

Clients with muscle function of C6 or better may be independent for light homemaking with appropriate devices, adaptations, and safety awareness. Many of the suggestions for wheelchair maneuverability and environmental adaptation outlined for someone with paraplegia apply here as well. In addition, clients with upper-extremity weakness need to use lightweight equipment and special devices. A classic book, *The Mealtime Manual for People with Disability and the Aging*, compiled by Klinger²⁵ contains many excellent specific suggestions that apply to homemakers with weak upper extremities. Specialty suppliers for cooking devices to make meal preparation and cooking easier and more efficient are an excellent source for new ideas. The kitchen and home sections of general national and international stores are other good resources for ideas and products. In this age of digital information-sharing, many people with various disabilities post themselves online performing ADL and IADL such as a woman with C6 quadriplegia who demonstrates many techniques and types of adaptations possible:⁴²

1. For faucets, use extended lever type faucets for easier reach and control or motion sensor faucets (SCI Level C5-7).
2. To eliminate the need for grasp and release, use pump bottles for cleaners and soaps or motion sensor dispensers (SCI Level C5-7).
3. For cooking utensils, see universal cuff adaptations or tenodesis splint or adapted long-handled utensils (SCI Level C5-7).
4. For opening cans, use one-touch can openers.
5. For opening jars, use electric jar openers.
6. To wash dishes, use a combination soap dispenser/sponge.
7. To wash and rinse lettuce, use a salad spinner with a push-button center.

ADLs for the Person with Low Vision

Many people with physical disabilities also have low vision as a result of advancing age, age-related eye diseases, or as a complication of diabetes. As part of a comprehensive OT evaluation, visual changes are considered. Evaluation of the person with low vision should initially involve understanding the specific condition that has caused the low vision such as whether visual acuity is affected or whether a specific field of vision is impaired. For more information on visual loss for the aging individual, please see [Chapter 46](#). The type of visual loss along with any other physical or cognitive deficits will influence treatment choices and adaptive equipment choices. Acquisition of low-vision assistive devices or services such as occupational therapy that address everyday activities has been shown to be highly valued by the client.¹⁵

In addition to assistive technology, adaptive equipment and environmental modifications, reorganization and task restructuring may be needed. Weiser-Pike provides a framework of intervention strategies to consider when addressing functional activities for the person with low vision. This framework has been modified to nine categories with some examples in each category ([Box 10-4](#)). The OT may use this model in combination with interventions under the specific functional activity as follows.

Adequate training and choice of appropriate intervention and adaptive equipment is essential. Consider [Box 10-4](#) as an activity analysis method to determine how the equipment might function for the person with low vision and how to implement training. This allows the OT practitioner to perform an activity analysis using the equipment prior to implementing instruction. Allow the client to touch and explore the piece of adaptive equipment before beginning practical teaching, break the steps down into small chunks of information, have the client practice a few days before doing the functional activity with the adaptive equipment, and request a return demonstration after the client has practiced.²²

The environmental modifications described in the following section are appropriate when performing ADLs for all persons with low vision.

Lighting and Magnifiers

1. Improve lighting by aiming light at the work area, not into the eyes.
2. Reduce glare by having adjustable blinds, sheer curtains, or tinted windows. Wearing dark glasses indoors may also reduce glare.

Box 10-4

Framework for Low-Vision Interventions

Use of Corrective Lenses

Have client wear glasses for activities as needed. Ask about most recent eye examination to make sure patient has most recent prescription.

Adequate Lighting

Examples include adding light that shines from behind the client onto the work area, avoiding glare, using natural light behind work area.

Good Ergonomic Positioning

Examples include raising reading material within field of vision and moving closer to an object such as the television or person.

Increase Contrast Enhancement

Examples include using black ink on white or yellow paper in an easy-to-read font, such as Times New Roman or Arial, if providing printed materials. Mark edges of doorways or stairs with contrasting strip.

Simplification of Environment

An example includes eliminating many pill bottles that create clutter and require numerous steps to manage by substituting a pill organizer.

Resize Written Materials

Larger print, larger television, larger label on pill bottles

Provide Sensory Substitutes

Use tactile or auditory cues such as rubber bands on doorknobs, rubber bands on frozen meals to indicate how many minutes an item should be cooked, talking books, and TV ears.

Restructure Routines

Utilize time of day when vision is the best to perform difficult activities, use pill organizer.

Visual Skills/Referrals

Refer to vision specialist or low-vision rehab specialist.

3. Maximize contrast by providing a work surface that is in contrast to the task. For example, serve a meal on a white plate if the table is dark. Paint a white edge on a dark step. Replace white wall switches with black to contrast with the wall.
4. Simplify figure-ground perception by clearing pathways and eliminating clutter.
5. Work in natural light by placing a chair by a window with the back toward the window.^{26,35}
6. Use magnifiers with lights. These come in a variety of sizes and degrees of magnification. Specialists in low vision can determine the appropriate degree of magnification needed. Some magnifiers are portable, others are attached to stands to do needlework or fine work, and others are sheets of plastic used to magnify an entire page of print.²¹

Dressing Activities

1. Light closet to improve acuity. Hang matching outfits together on the same hanger.
2. Place safety pin on the label of the backs of shirts/pants/dresses so that clothing is oriented correctly when worn.
3. Pin socks together when placing them in the washer and dryer so they will stay matched.

Feeding Activities

1. Provide high contrast. Ensure that plates contrast with table surface or place mats. Avoid patterned tablecloths.
2. Arrange food on the plate in a clockwise fashion and orient the person with low vision to the arrangement.

Personal Hygiene and Grooming Activities

1. Reduce clutter in bathroom drawers and cabinets.
2. Use an electric razor.
3. Use magnified mirrors.
4. Use a high-contrast bath mat in bathtub.
5. Install high-contrast grab bars in shower.

Communication and Environmental Hardware Adaptations

1. Use talking watches or clocks to tell time.
2. Use a talking scale to determine weight.
3. Use a large-print magnification screen on the computer.
4. Use high-contrast doorknobs. Paint the doorframe a color that contrasts highly with the door to improve ease of identifying the door.²⁶
5. Use speakerphones, preprogrammed phone numbers, or a phone with large print and high-contrast numbers. Identify phone buttons with contrasting tape or a Velcro dot to teach the client how to turn

the phone on and the correct buttons to push. Use a mobile phone with voice recognition commands.

6. Use writing guides to write letters, checks, or signatures.²¹
7. To read, use books on tape, talking books, electronic books, and digital books such as a Kindle or an iPad. Screens can be magnified, and some of the devices have “reading” capability so the reader can listen to a story or newspaper article. Software is available such as the JAWS screen reader, which reads aloud information that is on a computer screen.

Functional Mobility

Mobility is eased with the clearing of pathways and the minimizing of clutter and furniture. Lighting in hallways and entryways is also needed. The person with low vision needs to optimize visual scanning abilities by learning to turn and position the head frequently when mobile or participating in an activity.³⁵ The OT practitioner may need to refer a client to a specialist in low vision (such as an orientation and mobility specialist) who is specifically trained in teaching mobility in the community, such as human guide techniques, use of a white cane, and use of service animals to persons with low vision or who are legally blind.

Home Management, Meal Preparation, and Cleanup Activities

Various devices are available to compensate for low vision while managing the home. Organization and consistency are critical to the safe and efficient performance of home management tasks. Family members need to remember to replace items where they were found and not reorganize items without assistance from the person with low vision.

1. For safety, cleaning supplies should be placed separately from food supplies.
2. Eliminate extra hazardous cleaning supplies and replace with one multipurpose cleanser. Place this cleaning agent in a uniquely shaped bottle or in a specific location.
3. Mark appliance controls with high-contrast tape or paint to identify start and stop buttons or positions. Place Velcro tabs to mark frequently used positions on dials (e.g., on the 350 degrees position for the stove or for the wash-and-wear cycle on the washer or dryer).
4. Label cans by using rubber bands to attach index cards with bold, dark print to each can. When the can is used, the card may be placed into a stack to create a shopping list.
5. Indicate number of minutes needed for microwave cooking by placing rubber bands on the items. Two rubber bands would indicate that the item should be cooked for 2 minutes. Assistance will be needed for initial setup.

6. Use liquid level indicator to determine when hot liquid reaches 1 inch from top of cup or container.²⁶
7. Use cutting guides or specially designed knives to cut meat or bread.²¹
8. Use a tape recorder to make reminder lists or grocery lists.
9. Discourage use of long flowing gowns with flowing sleeves (e.g., kimono-style) while performing cooking tasks at the stove.

Medication Management

1. Use medication organizer to organize pills.
2. For diabetic management, many products are available for individualized evaluation of the client (e.g., syringe magnifiers, talking or large-print Glucometers, and a device to count the insulin dosages).
3. Use talking scales to evaluate weight.²⁴

Money Management

1. Use a consistent method of folding money to identify denominations, as in the following example:

\$1	Keep flat
\$5	Fold in square half
\$10	Fold lengthwise
\$20	Fold in half and then lengthwise

2. Keep different denominations in different sections of the wallet. Learn to recognize coins by size and type of edge (smooth or rough).³⁵

Leisure

1. Use low-vision playing cards with large letters and symbols.
2. Search for resources in the community for activities aimed at people with low vision.³⁷

Persons of Size/Body Mass

The terms *morbidly obese* and *bariatrics* both are used to describe the population that is exceptionally large. Morbidly obese is defined as an individual with a body mass index (BMI) of 40 or greater. This population is to be separated from individuals who fall into the overweight or obese category, as overweight and obese individuals most likely do not have functional deficits because of body size.

Individuals who are exceptionally large experience difficulty performing ADLs and IADLs.^{2,35,39} They may have difficulty with ADLs and IADLs because of limitations in reach strength, pain, and endurance. They may also experience neuropathies that require increased safety awareness to prevent skin breakdown. As with all clients, a comprehensive evaluation of the exceptionally large individual should include primary and secondary medical problems that result in additional functional deficits.

Adaptive techniques, adaptive equipment, and home modifications may allow for increased independence and safety. When recommending adaptive equipment and durable medical equipment, the size and durability of equipment needs to be taken into consideration. For example, the standard molded sock aid may not fit around the exceptionally large client's calf, whereas softer fabric or flexible plastic sock aids likely accommodate larger calf sizes.^{19,20}

Dressing

Provide resources for clothing available in larger sizes that may help the client to feel more comfortable in the community and help with self-esteem. Some manufacturers have designed exercise clothing, swimsuits, and work attire in larger sizes. Many resources can be found on the Internet that offer sizes up to at least 7x.

Lower-Extremity Dressing Activities

1. Use dressing sticks with a neoprene-covered coat hook on one end and a small hook on the other (see [Figure 10-7](#)) for pushing and pulling garments off and on feet and legs.
2. For socks, use a large flexible commercially available sock aid (see [Figure 10-8](#)). The rigid sock aids available may not fit around larger calves.
3. Compensate for the need to bend to tie shoelaces by using elastic shoelaces or other adapted shoe fasteners such as Velcro-fastened shoes or secure slip-on shoes. Edema is frequently a problem with this population and should be taken into account when selecting shoes.
4. Use reachers (see [Figure 10-9](#)) for picking up socks and shoes, arranging clothes, removing clothes from hangers, picking up objects on the floor, and donning pants to avoid bending or unsafe reaching.

Upper-Extremity Dressing Activities

1. Use front-opening or pullover garments that are one size larger than needed and made of fabrics that have some stretch.
2. Use dressing sticks (see [Figure 10-7](#)) to push a shirt or blouse over the head and reach around shoulders. Some exceptionally large individuals are not able to touch the opposite shoulder with the opposite hand because of the girth of their trunk.

Personal Hygiene and Grooming Activities

Bathing

1. A handheld flexible shower hose for bathing and shampooing hair can eliminate the need to stand in the shower and offers the user control of the direction of the spray.
2. A long-handled bath brush or sponge with a soap holder (see [Figure 10-13](#)) or long cloth scrubber can allow the user to reach legs, feet, and back. If the standard long-handled bath brush/sponge is not long

enough, add an extension with PVC pipe and a bend about one third of the distance from the handle to improve reach.

3. Safety rails (see Figure 10-15) can be used for bathtub transfers, and safety mats or strips can be placed on the bathtub bottom to prevent slipping.
4. A bariatric transfer tub bench (similar to Figure 10-6) or shower stool set in the bathtub or shower stall can eliminate the need to stand to shower, thus increasing safety and conserving energy. The bench should be built to accommodate the user's weight. The larger equipment may not be easily obtainable and may need to be special ordered. It is usually more functional to remove the back on the shower equipment to allow for increased sitting surface and room for posterior buttocks to shift back on the seat and allow the user to lean back as legs are lifted into shower or over the edge of the tub. The user must have adequate sitting balance before removing the back of the bench or stool.
5. Evaluate issues with water spillage from the tub or shower in using a transfer tub bench. A large person using a transfer tub bench that fits into the standard tub may need to plan ahead to manage water overflow because the width of the hips may cover the area on the bench originally designed for placement of the shower curtain. Water on the floor can lead to a fall and create extra cleanup. Extra towels may be required when setting up the shower.
6. Grab bars can be installed to prevent falls and ease transfers. A licensed contractor must securely mount these into the studs of the wall. The suction grab bars commercially available would not be safe for this population as the amount of pull and weight would cause the suction to release from the wall.
7. Use a hair dryer to thoroughly dry skin in hard-to-reach areas such as buttocks, crotch, or on abdominal folds to prevent rashes and fungal infections in the folds.

Grooming

1. Use a long-handle mirror for regular skin checks on feet to look for skin breakdown.
2. Over-the-counter spray products such as deodorant, hair spray, and spray powder can compensate for limited reach as the user does not need to make direct skin contact with the product. The spray can be aimed in the general direction—for example, the underarms—and provide adequate coverage.

Toileting

1. Use toilet paper holders/extenders for toilet hygiene as reach is often difficult for optimal hygiene. Several types of toilet aids are available in catalogs that sell assistive devices.

FIGURE 10-39 Bariatric commode.
(Courtesy North Coast Medical.)

2. Use a bidet mounted on the toilet for toilet hygiene. Select one where the controls are not mounted to the seat and likely to be covered by the user's wide hips. Many options are available from one as simple as a pump with a handheld spray to deluxe models that include front and rear wash, warm-air drying, and water pressure control.
3. Dressing sticks can be used to pull garments up after using the toilet.
4. Bariatric bedside commodes can be used over the toilet if room allows or at the bedside. The commode should be built to accommodate the user's weight. The sitting surfaces should be smooth to prevent skin tears or pressure areas. Because body size may push the large person forward, the standard hole size is not in the correct location for toileting. The commode hole should be larger than that for a standard commode to allow space to reach for toilet hygiene and proper alignment for elimination. If the user is not able to stand and pivot to the commode, drop-arm commodes are available for the bariatric population (Figure 10-39).
5. Adapt male urinals with a PVC pipe handle to allow for independent use. This will allow the use of one hand to hold the urinal and one hand to lift abdominal folds to place the urinal.

Functional Mobility

1. Set up furniture at appropriate height by raising on blocks to elevate or shortening leg rests to lower. Multiple sitting surfaces allow the large individual to alter sitting pressures during the day; elevate lower extremities, which may be prone to edema; and provide alternatives to staying in bed. Several manufacturers make electrical lifts for furniture or

- chairs that accommodate persons weighing up to 500 pounds.
2. A glider/office chair that is operated by the feet can facilitate transportation if lower-extremity endurance is limited. It should be built to accommodate the user's weight, and the user should be able to demonstrate safe sit to stand, as the chair is mobile without brakes to secure it during transfers.
 3. Encourage the use of mobility aids for safety. A four-wheeled walker with a seat may improve mobility and will improve function as the seat can be used as an energy-conservation method and be used to carry items on the seat when moving from room to room. The user can sit on the four-wheeled walker seat to conserve energy while cooking, brushing teeth, shaving, and washing.
 4. For the exceptionally large individual with limited functional mobility, a manual wheelchair is generally not functional as it is too wide for most doorways within the home. If discharged home with a seat width greater than 24 inches, the user is likely to only use it in one room as doorways in most homes are too narrow to accommodate such a large wheelchair. The OT and team should consider alternatives if a bariatric wheelchair is needed but access is limited.
 5. Eliminate bending by using extended and flexible plastic handles on dust mops, brooms, and dustpans. Sit to do cleaning and move chair as needed.
 6. Use pullout shelves or lazy Susans to organize cupboards to eliminate bending and to ease access to items.
 7. Eliminate bending by using a wall oven, countertop broiler, microwave oven, and convection oven.
 8. Use a metal kitchen spatula to pull out and push in oven racks. There are commercially available tools for this purpose also.
 9. Eliminate leaning and bending by using a top-loading automatic washer and elevated dryer. Wheelchair users or people of shorter stature can benefit from front-loading appliances. Use a reacher or other extended tool to obtain clothes from the washer or dryer.
 10. Use an adjustable ironing board to make it possible to sit while ironing, or eliminate ironing with the use of permanently pressed clothing.^{2,19,20,35,39}

Summary

ADLs and IADLs are areas of occupation that include activities that enable a person to function independently and assume important occupational roles. ADLs include self-care tasks such as bathing/showering, bowel and bladder management, dressing/undressing, eating (or swallowing), feeding, functional mobility such as transfers and bed mobility, sexual activity, toilet hygiene, and the care of personal devices such as hearing aids, orthotics, and splints. IADL tasks include care of others and of pets, child rearing, communication management such as use of telephones, use of personal digital assistants and computers, community mobility such as driving and use of public transportation, financial management such as use of cash and check writing, health management, and maintenance.

Occupational therapists routinely assess performance in ADLs and IADLs to determine a client's level of functional independence. Interviews and performance analysis are used to carry out the assessment. Performance skills, performance patterns, the environment, and cultural, personal, temporal, and virtual context are also evaluated and taken into consideration when evaluating and establishing treatment goals.

Results of the assessment and ongoing progress are recorded on one of many available ADL checklists or with a standardized assessment, the content of which is summarized for the permanent medical record (please refer to [Chapter 8](#) for further information on documentation). Intervention is client centered and directed at training in independent living skills or with teaching a caregiver to assist the client with ADLs and IADLs. The occupational therapist can include in the intervention plan compensatory strategies, home modification, adaptive equipment, durable medical equipment, work simplification, and energy conservation techniques to improve ADL/IADL performance.

Home Management, Meal Preparation, and Cleanup Activities

The exceptionally large person may be unable to reach faucet handles, reach into lower cabinets or a clothes dryer, be safe on step stools, or carry heavy items with proper body mechanics because of obstructions caused by abdomen size, limited endurance, and limited reaching and bending. Home management activities can be facilitated by a wide variety of environmental adaptations, assistive devices, energy conservation methods, and work simplification techniques.^{12,44} The following are suggestions to facilitate home management for the exceptionally large individual:

1. Store frequently used items on the first shelves of cabinets, just above and below counters or on counters where possible. Eliminate unnecessary items.
2. If the individual is unable to reach faucet handles, add an extension onto the handle.
3. Use a high stable stool to work comfortably at counter height with feet firmly placed on the ground, or attach a drop-leaf table to the wall for planning and meal preparation area if a wheelchair is used.
4. Use a utility cart of comfortable height to transport several items at once or a four-wheeled walker.
5. Use reachers to get lightweight items (e.g., a cereal box) from high shelves. Place frequently used items on shelves in cabinets and refrigerator where items are easily accessible and reachable.

Threaded Case Study Anna, Part 2

At the beginning of this chapter, Anna's case introduced questions regarding ADL and IADL participation. Anna identified many ADLs and IADLs that she wanted to engage in as independently as possible, such as self-care, child rearing, religious activities, community mobility, financial management, home management, meal preparation and cleanup, and shopping. All of these areas are in the domain of occupational therapy and can be addressed while Anna is in the inpatient setting and further along in the continuum of care. With the many areas that must be addressed, an occupational therapist along with client/family/rehabilitation team input must prioritize which areas to address at each stage. Prior to discharge home, a home evaluation is indicated for safety and accessibility as is an assessment for appropriate durable medical equipment such as a wheelchair and padded bath bench. Other equipment and adaptive techniques in ADLs and IADLs may also be recommended to foster Anna's independence and return to her roles as mother, wife, worker, and active community member.

Review Questions

1. Define ADLs and IADLs. List three classifications of tasks that may be considered in each category.
2. What is the role of OT in restoring ADL and IADL independence?
3. List at least three activities that are considered self-care skills, three functional mobility skills, three functional communication skills, and three home management or meal preparation and cleanup skills.
4. List three factors that the occupational therapist must consider before commencing ADL performance assessment and training. Describe how each could limit or affect ADL performance.
5. What is the ultimate goal of the ADL and IADL training program?
6. Discuss the concept of maximal independence, as defined in the text.
7. List the general steps in the procedure for ADL assessment.
8. Describe how the occupational therapist can use the ADL checklist.
9. List the steps in the activities of IADL assessment, and describe who should be involved in a home evaluation.
10. What is the purpose of the home evaluation?
11. List the steps in the home evaluation.
12. What kinds of things are observed in a home assessment?
13. How does the therapist record and report the results of the home evaluation and make the necessary recommendations?

14. How does the occupational therapist, with the client, select ADL and IADL training objectives after an assessment?
15. Describe three approaches to teaching ADL skills to a client with perception or memory deficits.
16. List the important factors to include in an ADL or IADL progress report.
17. Describe the levels of independence, as defined in the text.
18. Give an example of a health management and maintenance issue.
19. Give three examples of adaptations that may be helpful for the person with low vision.

Exercises

1. Demonstrate the use of at least three assistive devices mentioned in the text.
2. Teach another person to don a shirt using one hand.
3. Teach another person how to don and remove trousers as if he or she had hemiplegia.
4. Teach another person how to don and remove trousers as if his or her legs were paralyzed.
5. Prepare a meal using only one hand, and write about your experience.

■ Learning Objectives *After studying this chapter, the student or practitioner will be able to do the following:*

1. Define functional ambulation.
2. Discuss the roles of physical and occupational therapists and other caregivers in functional ambulation.
3. Identify safety issues in functional ambulation.
4. Recognize basic lower extremity orthotics and ambulation aids.
5. Develop goals and plans that can help ambulatory clients resume occupational roles.
6. Identify the components necessary to perform a wheelchair evaluation.
7. Explain the process of wheelchair measurement and prescription completion.
8. Identify wheelchair safety considerations.

■ Learning Objectives—cont'd

9. Follow guidelines for proper body mechanics.
10. Apply principles of proper body positioning.
11. Identify the steps necessary for performing various transfer techniques.
12. Identify considerations necessary to determine the appropriate transfer method based on the client's clinical presentation.
13. Identify different transportation systems and contexts and the treatment implications each system presents.
14. Discuss the multilevel role of the therapist in the occupation of community mobility.
15. List performance skills and client factors that should be assessed in a comprehensive driver evaluation.
16. Discuss the value of driving within this society and how loss of license or mobility affects participation in occupation.
17. Develop awareness of the complexities involved in a driver referral and evaluation.
18. Define primary and secondary controls.
19. Discuss that driver competency assessment is a specialty practice area requiring advanced training.

Walking, climbing stairs, traveling within one's neighborhood, and **driving** a car are so universal and customary that most people would not consider these to be complex activities. The basic capacities to move within the environment, to reach objects of interest, to explore one's surroundings, and to come and go at will appear natural and easy. For persons with disabilities, however, mobility is rarely taken for granted or thought of as automatic. A disability may prevent a person from using the legs to walk or using the hands to operate controls of motor vehicles. Cardiopulmonary and medical conditions may limit aerobic capacity or endurance, requiring the person to take frequent rests and to curtail walking to cover only the most basic of needs, such as toileting. Deficits in motor coordination, flexibility, and strength may seriously compromise movement and may make difficult any activities that require a combination of mobility (e.g., walking or moving in the environment) and stability (e.g., holding the hands steady when carrying a cup of coffee or a watering can).

Occupational therapy (OT) practitioners assist persons with mobility restrictions to achieve maximum access to environments and objects of interest to them. Typically, OT practitioners provide remediation and compensatory training. In so doing, therapists must analyze the activities most valued and the environments most often used by their clients and must consider any future changes that can be predicted from an individual's medical history, prognosis, and developmental status.

This chapter guides the practitioner in evaluation and intervention for persons with mobility restrictions. Three main topics are explored. The first section addresses **functional ambulation**, which combines the act of walking within one's immediate environment (e.g., home, workplace) with other activities chosen by the individual. Feeding pets, preparing a meal and carrying it to a table, and doing simple housework are tasks that may involve functional ambulation. Functional ambulation may be conducted with aids such as walkers, canes, or crutches.

The second section concerns wheelchairs and their selection, measurement, fitting, and use. For many persons with

disabilities, mobility becomes possible only with a wheelchair and specific positioning devices. Consequently, individual evaluation is needed to select and fit this essential piece of personal medical equipment. Proper training in ergonomic use allows the person who is dependent on the use of a wheelchair many years of safe and comfortable mobility. Safe and efficient transfer techniques based on the individual's clinical status are introduced in this chapter. Attention also is given to the **body mechanics** required to safely assist an individual.

The third section covers **community mobility**, which for many in the United States is synonymous with driving. Increased advocacy by and for persons with disabilities has improved access and has yielded an increasing range of options for adapting motor vehicles to meet individual needs. Public transportation also has become increasingly accessible. Driving is a complex activity that requires multiple cognitive and perceptual skills. Evaluation of individuals with medical conditions and physical limitations is thus important for the safety of the disabled person and the public at large.

Mobility is an area of OT practice that requires close coordination with other health care providers, particularly physical therapists (PTs) and providers of **durable medical equipment**. Improving and maintaining the functional and community mobility of persons with disabilities can be one of the most gratifying practice areas. Clients experience tremendous energy and empowerment when they are able to access and explore wider and more interesting environments.

■ SECTION 1 | Functional Ambulation

DEBORAH BOLDING

Occupational therapists (OTs) work with many types of clients who may have impaired ambulation because of disease or trauma. These impairments may be temporary or

Threaded Case Study | Pyia, Part 1

Pyia is a 75-year-old woman who was treated for breast cancer 8 years earlier. She developed spinal metastases, with an onset of acute, bilateral lower extremity weakness and loss of sensation. For 2 days, she felt “unsteady” when she was walking and had one fall. By the time she was admitted to the hospital, she was unable to walk. She underwent a laminectomy and decompression of the spinal cord, with debulking of the tumor, followed by cyberknife treatment.

Pyia was hospitalized for 1 day before her surgery and for 4 days after the surgery. Postoperatively, she learned to ambulate 50 feet with a front-wheeled walker and minimal assistance, and to get on and off a commode chair. She required an ankle-foot orthosis (AFO) for her left foot. Pyia was discharged from the hospital to stay with her daughter and had a rental wheelchair for community mobility. A referral for home-based occupational and physical therapy was made through a home care agency.

An occupational profile provided the following information about Pyia. Pyia was widowed and lived alone in a three-bedroom house with three steps by which to enter the home. She retired from retail sales when she was 62. She was independent in driving, was active in her church, and attended occasional programs at the local senior citizens' center. She volunteered 3 hours per week at a thrift shop that benefits the local children's hospital. Pyia has two close friends that she used to go to lunch with each Tuesday. Pyia has three children—two sons living in other states, and a daughter who lives in the same town. She has two grandchildren, ages 10 and 13, who live nearby. Two to three times per year, she would fly to visit her sons.

An important part of Pyia's life for the past few years was going to her daughter's home one to two afternoons per week. She would help watch the grandchildren after school or drive them to activities while their parents worked. She would also help her daughter with laundry and dinner preparation.

After 3 weeks at her daughter's home, Pyia was asked to identify what areas of occupational performance were still

problematic for her, what she could do well, and what her goals were. She replied that she was happy to be walking better but felt endurance was still a problem. She used the walker independently in the home but still needed assistance to get up and down stairs. The PT felt that she soon would be independent with stairs and may be able to transition to a cane, as her lower extremity strength, especially in her right leg, had improved. Pyia was able to walk to the bathroom and to use a toilet independently and was independent in dressing. Her daughter helped her into and out of the tub for safety reasons, and she used a stool in the tub for bathing. She was able to prepare a simple breakfast and lunch but needed a rest period each morning and afternoon.

Pyia felt like a burden to her daughter and son-in-law. She felt guilty that her daughter had taken a week off work after her hospitalization to be with her at home, and that her son had to visit to help her for the second week. She was happy that she could now take care of herself during the day but would like to be able to help with household chores. She had to rely on her family and friends to drive her to doctors' appointments and will need them to drive her to therapy appointments the following week as she transitions to outpatient care. Pyia wished that she could return to her home but recognized that she was not yet ready. Her old friends brought lunch to her daughter's home the previous Tuesday, and she was grateful for their support and the support she received from her pastor and church.

Critical Thinking Questions

1. How did Pyia's needs, goals, and occupational roles change during the course of her illness and recuperation?
2. Where would you start your intervention plan considering her current goals?
3. What are safety issues, and how would you address them?

long term. For example, an elderly person with a hip fracture may require the use of a walker for several weeks or months until the bone is healed and strength is regained. Persons with a spinal cord injury may have permanent motor and sensory losses that require lower extremity bracing and the use of crutches for walking. They may be ambulatory only part of the time and may use a wheelchair part of the time. This depends on several factors, including the level of injury, the amount of energy required for ambulation, and their occupational roles.

Functional ambulation, a component of functional mobility, is the term used to describe how a person walks while achieving a goal, such as carrying a plate to the table or carrying groceries from the car to the house. Functional ambulation training is applicable for all individuals with safety or functional impairments and for a variety of

diagnoses, such as lower extremity amputation, cerebrovascular accident, brain trauma or tumor, neurologic disease, spinal cord injury, orthopedic injury, and total hip or knee replacement.

Ambulation evaluation, **gait training** (treatments used to improve walking and ameliorate deviations from normal gait), and recommendations for bracing and **ambulation aids** are included in the professional role of the PT. The PT makes recommendations that can be followed by the client, families, hospital staff, or other caregivers. The OT works closely with colleagues in physical therapy to determine when clients may be ready to advance to the next levels of functional performance. For example, the OT may begin to have a client walk to the bathroom for toileting instead of using a bedside commode when the PT reports that the client is safe to walk the distance from the bed to the

bathroom. The PT may recommend certain techniques or cueing to improve safety. Mutual respect and good communication between all team members help in coordination of care for clients. For example, a client with Parkinson's disease may walk well with the PT immediately after taking his medication in the morning, but may have difficulty preparing lunch a few hours later, when the effects of medication are waning.

The following section is meant to provide an introduction to the OT about the basics of ambulation and aids such as crutches, canes, walkers, and braces to assist with teaching of activities of daily living (ADLs). It is not meant as a substitute for close collaboration with a PT.

Basics of Ambulation

Normal walking is a method of using two legs, alternately, to provide support and propulsion. Gait and walking are often used interchangeably, but gait more accurately describes the style of walking. The "normal" pattern of walking includes components of body support on each leg alternately (stance phase), advancement of the swinging leg to allow it to take over a supporting role (swing phase), balance, and power to move the legs and trunk. Normal walking is achieved without difficulty and with minimal energy consumption.

Descriptors of the events of walking include loading response, midstance, terminal stance and pre-swing, and midswing and terminal swing, with the duration of the complete cycle called *cycle time*. Cadence is the average step rate. Stride length is the distance between two placements of the same foot. It may be shortened in people with a variety of diseases. Walking base is the distance between the line of the two feet. It may be wider than normal for people with balance deficits.¹⁶²

Abnormal gait is caused by disorders of the complex interaction between neuromuscular and structural elements of the body. It may result from problems with the brain, spinal cord, nerves, muscles, joints, or skeleton, or from pain. Problems may include weakness, paralysis, ataxia, spasticity, loss of sensation, and inability to bear weight through the limb or pelvis. Deficits may include decreased velocity, decreased weight bearing, increased swing time of the affected leg, an abnormal base of support, and balance problems. Functional deficits may include loss of mobility, decreased safety (increased fall risk), and insufficient endurance. The OT should reinforce gait training by following the recommendations of the PT.

Orthotics

As the PT evaluates the causes of gait problems, orthotics and ambulatory aids may be recommended. The OT should be familiar with basic lower extremity (LE) orthotics, including the reason for bracing. The OT may teach clients to put on the orthotics as part of dressing training.

Orthotics, or braces, are used to provide support and stability for a joint, to prevent deformity, or to replace lost function. They should be comfortable, easy to apply, and lightweight, if possible. The more joints of the lower extremity require bracing, the higher is the energy cost of ambulation.

Orthotics are named by the part of the body that is supported. A supramalleolar orthosis (SMO, or SMAFO) is made of plastic and fits into a shoe. It provides medial-lateral stability at the ankle, provides rear foot alignment during gait, supports midfoot laxity, and can control pronation/supination positions of the forefoot. It is not useful in cases of high tone or limited dorsiflexion. An ankle-foot orthosis (AFO) is usually made of plastic; it inserts into a shoe and extends up the back of the lower leg. It is sometimes called a *foot drop* splint, because it is used in cases of central or peripheral nerve lesions, which cause weakness of ankle dorsiflexors. An AFO may consist of one piece or may be hinged to permit ankle dorsiflexion. A knee-ankle-foot orthosis (KAFO) may be recommended for clients with knee weakness or hyperextension, or with foot problems. The KAFO might be used with diagnoses such as paraplegia, cerebral palsy, or spina bifida. For clients with spinal cord lesions or spina bifida involving the hip muscles, a hip-knee-ankle-foot orthosis (HKAFO) might be used. A reciprocating gait orthosis (RGO) is a type of HKAFO that may be used to help advance the hip in the presence of hip flexor weakness. High energy costs are associated with use of HKAFOs, and clients' upper extremities are used for support on walkers and crutches. This makes functional ambulation tasks extremely challenging for these clients, and it may be more energy efficient and safer to perform some tasks while seated in a chair or wheelchair.

Walking Aids

Ambulation aids may be used to compensate for deficits in balance and strength, to decrease pain, and to decrease weight bearing on involved joints and help with fracture healing, or in the absence of a lower extremity. Walking aids are generally classified as canes, crutches, and walkers. All three help support part of the body weight through the arm or arms during gait. They may also be sensory cues for balance and may enhance stability by increasing the size of the base of support.

A single-point cane may be used with clients who have minor balance problems, by widening the base of support or providing sensory feedback through the upper extremity about position. For clients with a painful hip or knee, a cane is most commonly used on the contralateral side to reduce loading on the painful joint. The cane is advanced during the swing phase of the leg it is protecting. Variations of cane designs include quad canes and hemi-walkers that are heavier and bulkier than single-point canes but provide greater stability.

Crutches are able to transmit forces in a horizontal plane because two points of attachment exist—one at the hand

and the other higher on the arm. Clients should be cautioned not to lean on crutches at the axilla because this may cause damage to blood vessels or nerves. The lever between the axilla and the hand is long, and enough horizontal force can be generated to permit walking when one leg has restricted weight-bearing capacity, or when both legs are straight and have limited or no weight-bearing capacity. Crutches are suitable for short-term use, such as for a fractured leg.

Forearm crutches may also be called *Lofstrand* or *Canadian crutches*. The points of contact are on the hand and forearm. The lever arm is shorter than with axillary crutches, and they are lighter. Mobility is easier for most people using Lofstrand or forearm crutches than when using axillary crutches, and they are useful for active people with severe leg weakness. All crutches require good upper body strength.

Walkers are more stable than canes or crutches. With a “pick-up” style walker, the walker is moved first; the client takes a short step with each foot and then moves the walker again. This type of walking can be slow. Most clients who need a walker are able to use a “front-wheeled walker,” which has two wheels on the front, making it lighter and easier to advance. Another variation is to have four wheels, along with a braking system. Some walkers have seats so that clients can rest when they become fatigued. Walkers require the use of both arms but do not require as much upper body strength or balance as crutches. Forearm platforms can be added to forearm crutches or walkers when clients are unable to bear weight through their hands or wrists, perhaps because of fracture or arthritis. For example, Pyia is currently using a walker that supplies substantial support during ambulation but requires additional energy to use compared with a cane. The PT may recommend a cane as Pyia progresses, but a walker may still be necessary in some situations within the home environment.

Ambulation Techniques

Basic ambulation techniques recommended by the PT vary from client to client, depending on the individual’s goals, strengths, and weaknesses and may be more complex than the descriptions provided previously. The OT reinforces the PT’s recommendations and incorporates them into functional ambulation activities.

During functional ambulation on a level surface, the OT is positioned slightly behind and to one side of the client. The therapist may be on the client’s stronger or weaker side, based on the recommendations and preference of the PT or the goals of the activity. The therapist moves in tandem with the client when providing support during ambulation. The therapist’s outermost lower extremity moves with the ambulation aid, and the therapist’s inside foot moves forward with the client’s lower extremity. Of course, some clients may be independent with basic ambulation and may need guarding or assistance only when practicing new activities, such as transporting hot foods, mopping a floor, or reaching into a dryer.

OT Practice Note

Safety for Functional Ambulation

1. Know the client (e.g., status, orthotics and aids, precautions).
2. Use appropriate footwear.
3. Monitor physiologic responses.
4. Use a gait belt to guide the client. Do not use the client’s clothes or upper extremity to guide the client.
5. Think ahead for the unexpected.
6. Do not leave the client unattended.
7. Clear potential hazards.

Safety

Safety is the number one priority for clients during functional ambulation. Before beginning an evaluation of ADLs, the OT should know basic client information. The therapist reviews the medical record, especially the current status and precautions. Does the client use oxygen? Does it need to be increased during activity? In the hospital setting, it may be useful to be aware of hematocrit level, if available, to help predict how much activity the client may be able to tolerate. The therapist should review physical therapy reports and confer with the PT as needed about gait techniques, aids, orthotics, and ambulatory status. To prepare the client for functional ambulation, the therapist and the client should have safe and appropriate footwear. Soft-soled shoes or shoes with a slippery sole should be avoided, and slippers or shoes without a heel support can compromise safety and stability for the client.

Another key to safe and successful ADLs is awareness of the client’s endurance level, including the distance the client is able to ambulate. It is very important to plan ahead for the activity. The therapist should have a wheelchair, a chair, or a stool readily available for use at appropriate intervals or in case of need caused by client fatigue. The area should be free of potential safety hazards, such as throw rugs or other objects on the floor. In certain cases, however, as with a client with unilateral neglect, hemianopsia, or visual or perceptual deficits, the therapist may want to challenge the client to manage in a complex environment.

The client’s physiologic responses should be monitored during the activity. The therapist should be aware of the client’s precautions and should respond appropriately. Physiologic responses may include a change in breathing patterns, perspiration, reddened or pale skin, a change in mental status, and decreased responsiveness. These changes may require termination of the activity to allow the client a period of rest. Recall that Pyia continues to experience limited endurance and easily fatigues. Activities that require sustained standing or walking may be too challenging at this time.

Elderly clients who use assistive devices for ambulation before hospitalization are particularly at risk for loss of ADL and instrumental activities of daily living (IADL) function after hospitalization. A history of use of assistive devices may be a marker for decreased ability to recover.⁹⁸ It may be important to target these elderly for intensive therapy to maintain function.

Falls represent a major problem in the elderly. Studies suggest that one fourth of persons aged 65 to 79 and half of those older than 80 fall every year.⁴⁸ Falls result from many factors, including both intrinsic (e.g., health, existence of balance disorders) and external, or environmental, factors. Home hazards include poor lighting, inadequate bathroom grab rails, inadequate stair rails, exposed electrical cords, items on the floors, and throw rugs. Elderly people with health problems such as cardiac disease, stroke, and degenerative neurologic conditions have an even greater risk of falling.^{93,133} OTs may visit the client's home while the client is hospitalized or may work through home health agencies, fall prevention programs, or senior citizen centers to help evaluate homes for potential hazards.¹¹⁵ All reasonable efforts should be made to decrease the risk of falls.

If a client loses his or her balance or stumbles, the therapist will have better control of the client if he or she is holding onto the client's trunk. Therapists may be less prone to injure their own backs if they are using their legs to support or lower the client to the floor instead of pulling or twisting with the upper body. For a client who feels faint or develops sudden leg weakness, the therapist lowers the client onto the therapist's flexed leg, like onto a chair, then down to the floor.

OT Practice Note

All clients who are at risk for falling and who are alone for significant periods of time should be connected to a lifeline-type phone system, where help can be summoned in the event of a fall or other emergency. Local hospitals or senior citizen centers will have further information about lifeline services.

OT Practice Note

The therapist must develop a good working relationship with the equipment supplier and the reimbursement sources to facilitate payment of the most appropriate mobility system for the client. The therapist must have the oral and written documentation skills needed to clearly communicate the medical necessity, appropriateness, and cost-effectiveness of each item throughout the assessment and recommendation process.

Functional Ambulation

Functional ambulation integrates ambulation into ADLs and IADLs. By using an occupationally based approach, the OT assesses the client's abilities within the performance context and with an understanding of client habits, routines, and roles. What role(s) does the client have or want to have? What tasks does this role require? The OT plans for functional mobility activities with the goal of helping the client achieve valued roles and activities. Several typical functional ambulation activities follow. These activities must be individualized for clients. Functional ambulation may be incorporated during ADLs, IADLs, work, play, or leisure activities.

Kitchen Ambulation

Meal preparation and cleanup involve many different tasks, such as opening and reaching into a refrigerator, dishwasher, stove, microwave, and cupboards. This often involves transporting items within the kitchen and to a table. If something is dropped, the item will need to be retrieved from the floor. The task may be relatively quick and easy, such as heating food in a microwave, or may require someone to stand while chopping, stirring, or cooking food. The OT can help the client engage in problem-solving strategies on how to safely accomplish these tasks. For example, clients with left hemiplegia who ambulate with a quad cane may be guided to the left of the oven so that they can open the oven door by using the unaffected right upper extremity. The same concept should be kept in mind for opening cabinet doors or drawers or refrigerator doors. The therapist can help assess the client's safety during these tasks and can recommend alternatives as needed. If the client is unable to successfully balance and reach into the oven, a toaster oven on the counter may be a safer alternative. Clients can place frequently needed items in convenient locations, or equipment such as a reacher may be needed. If the reacher is applied to a walker with Velcro, it is usually available when the client needs it. Clients may be able to pick up items from the floor by kicking or pushing the item close to a counter, where they can hold onto the counter while bending to pick up the item. If they have had a total hip replacement and have hip flexion precautions, they can position the affected leg behind them, being careful to not internally rotate the hip, while they reach down to the floor.

Transporting items such as food, plates, and eating utensils during functional ambulation invites creative problem solving on the part of the OT, particularly when the client is using an ambulation aid (Figures 11-1 and 11-2). Baskets attached to a walker, rolling carts, or countertops on which to slide the item may be appropriate in these situations. Clients must clearly desire the equipment or adaptations, and care should be taken not to provide unwanted or unnecessary equipment. A client who does not live alone may prefer to share jobs with other family members, that is, the client may do the cooking while a family member

FIGURE 11-1 Functional ambulation with a walker and walker basket.

FIGURE 11-2 Functional ambulation with a straight cane.

sets and clears the table. Although Pyia was able to prepare a simple meal, she still experiences fatigue after doing so and is unable to assist her daughter in meal preparation. Suggestions regarding adaptations and energy conservation techniques may support Pyia's goal of being able to help with this activity while still living with her daughter.

Bathroom Ambulation

Functional ambulation to the sink, toilet, bathtub, or shower is an important concern for the client. Care should be taken during activities in the bathroom because of the many risks associated with water and hard surfaces. Spills on the floor are slipping hazards, and loose bath mats are tripping hazards. Clients must be educated about these dangers. Nonslip surfaces or mats should be used on tub and shower floors.

Functional ambulation to the sink using a walker may be performed by having the client approach the sink as closely as possible. If the walker has a walker basket, the client can position the walker at the side of the sink; then while holding onto the walker with one hand and the sink or countertop with the other, the patient can turn to face the sink.

The importance of helping the client become as independent as possible in toileting cannot be overemphasized.

People who are unsure about their abilities to safely use a toilet in friends' or families' homes, in restaurants, in the mall, or at gas stations may become homebound as a result. When safe to do so, practice toileting in a variety of settings and with and without equipment such as commodes or elevating toilet seats and grab bars. One limiting factor may be postoperative precautions: A tall client who has had a total hip replacement may not be able to sit safely on a regular toilet while observing the postsurgical precaution of no hip flexion greater than 90 degrees. A shorter client may be able to sit successfully on a toilet of regular height without difficulty. If a client is unable to get up and down from the toilet without assistance, or if he or she does so with difficulty, consult the PT, who can provide the client with lower extremity strengthening exercises.

When the client is ambulating to a tub or shower, make sure the equipment and supplies are in position for the client to use. While stepping into a shower stall with a low rim, clients use the same technique that they would use to go up a curb or step, using their walking aid if it fits into the door of the shower. If the walking aid does not fit, the therapist can evaluate the client's ability to safely step in without the equipment. A client who has non-weight-bearing precautions on a leg will not be able to step into a shower without walking aids, and will not step into a tub.

A tub bench must be used for non-weight-bearing clients who have access only to tubs. Pyia is able to negotiate her daughter's home and to use the toilet but still requires assistance to transfer into and out of the tub. These skills will have to be addressed before Pyia can return to her own home.

Grab bars are important safety items for clients in the shower and tub. The therapist may want to practice shower or tub transfers under trial conditions before practicing an actual shower or bath. Some older persons have become accustomed to taking sponge baths because of a fear of falling in the bathroom. The therapist should determine whether the client is satisfied with this system or would like to work toward independent showering.

Home Management Ambulation

The ability to live alone is closely tied to the ability to perform IADLs.⁹⁶ Home management activities include cleaning, laundry, and household maintenance. Cleaning includes tidying, vacuuming, sweeping and mopping floors, dusting, and making beds. Clients may balance with one hand and hold onto a counter or a sturdy piece of furniture while cleaning floors if they are not stable independently or are using a walking aid. Lightweight duster-style sweepers, which come with dry or wet replaceable pads, are easy to handle and use. When making the bed, the client can stabilize himself or herself on the bed or walking aid while straightening and pulling up sheets and bedcovers. The client then moves around the bed to the other side to repeat the process. Some clients find that carrying items in a small fanny pack or shoulder bag slung over the neck is an easy way to transport small items such as cordless phones, bottled water, and books. Moving clothes to or from a laundry room may present a challenge for people with mobility impairments, particularly if they use a walking aid. Rolling carts may be useful to transport items to the laundry and in the kitchen. Some clients carry items over the front of their walkers, in a bag attached to the walker, or in a bag that they hold while walking with crutches or a cane. Whichever method is safe for the client is acceptable. Watch to make sure that the clothes do not shift while clients carry them; this may throw them off balance.

Other home management activities may include maintenance of the yard, garden, appliances, and vehicles. The client should be consulted to determine the home management activity most valued by the client before the functional activity is begun. Sometimes the client has goals that the therapist does not believe are safe for the client to perform. For example, the client who has had a mild stroke who wants to climb a ladder and trim tree branches with his power saw may need to be persuaded to wait until his balance and strength are improved. Although this is a valued activity, it may be incompatible with the client's functional abilities at the time. Gardening is an area in which the PT and the OT may wish to collaborate. The PT helps the client learn to maneuver over uneven surfaces and get up

and down from the ground, whereas the OT helps the client learn how to carry tools and other equipment and how to dispose of clippings and weeds.

In case of falls, clients should learn how to get up and down from the floor or ground during physical therapy sessions. It may be a functional activity with the OT when clients want to be able to get to the bottom of a tub, reach objects stored under a bed, or sit on the floor to play with their grandchildren.

Therapists should listen to clients about the techniques that clients have developed to be independent and safe. Some clients with fall risks manage to walk to the bathroom from their bed every night without putting on braces and/or using equipment. They will say things such as, "I lean against the wall as I walk," or "There is a couch there, and I brace myself on the back." If the technique is safe, and if the client has not had falls, the routine may not need modification.

Summary

Functional ambulation may be incorporated during ADLs, IADLs, work and productive activities, and play or leisure. OTs and PTs have an opportunity to collaborate, with the PT providing gait training, exercises, and ambulation aid recommendations, and the OT reinforcing training and integrating it during purposeful activities.

Threaded Case Study Pyia, Part 2

With regard to our case study, Pyia's roles as homemaker, caregiver, grandmother, mother, and volunteer changed with her illness. Her role became more passive as others became her caregivers. Initially, she was very concerned about her disease, whether and how long she would live, and if she would ever be able to walk again. After surgery, her goals were to be able to walk, and to go to her daughter's home. Once this was achieved, she began to experience loss about her change in roles and to plan for the future: taking care of herself during the day, resuming homemaking activities, planning a return to her own home, visiting with her friends, and becoming more independent in the community.

Pyia is home alone during the day. She would like to be more active with homemaking, both to help her daughter and to prepare for the return to her own home. The therapist could begin practice on laundry and cleaning. Pyia is already able to do basic meal preparation. The therapist could help assess safety in Pyia's home, make recommendations for equipment or modifications, and refer the family for lifeline services. Pyia might arrange transportation services for the disabled through her county, or she could have a driver's evaluation to determine whether she could start to drive again. She would need to be able to get into and out of the car safely, and to put her walker and other items in the car.

SECTION 2 | Wheelchair Assessment and Transfers

MICHELLE TIPTON-BURTON
with contributions from CAROL ADLER

Wheelchairs

A wheelchair can be the primary means of mobility for someone with a permanent or progressive disability such as cerebral palsy, brain injury, spinal cord injury, multiple sclerosis, or muscular dystrophy. Someone with a short-term

illness or orthopedic problem may need it as a temporary means of mobility. In addition to mobility, the wheelchair can substantially influence total body positioning, skin integrity, overall function, and the general well-being of the client. Regardless of the diagnosis of the client's condition, the OT must understand the complexity of wheelchair technology, available options and modifications, the evaluation and measuring process, the use, care, and cost of the wheelchair, and the process by which this equipment is funded.

Wheelchairs have evolved considerably in recent years, and significant advances have been made in powered and manual wheelchair technology by manufacturers and service providers. Products are constantly changing. Many improvements are the result of user and therapist recommendations.

OTs and PTs, depending on their respective roles at their treatment facilities, are usually responsible for evaluation, measurement, and selection of a wheelchair and seating system for the client. They also teach wheelchair safety and mobility skills to clients and their caregivers. The constant evolution of technology and the variety of manufacturers' products make it advisable to include an experienced, knowledgeable, and certified assistive technology practitioner (ATP) on the ordering team. The ATP is a supplier of durable medical equipment (DME) who is proficient in ordering custom items and can offer an objective and broad mechanical perspective on the availability and appropriateness of the options being considered. The ATP will serve as the client's resource for insurance billing, repairs, and reordering upon returning to the community.

Whether the client requires a noncustom rental wheelchair for temporary use or a custom wheelchair for use over many years, an individualized prescription clearly outlining the specific features of the wheelchair is needed to ensure optimal performance, safety, mobility, and enhancement of function. A wheelchair that has been prescribed by an inexperienced or nonclinical person is potentially hazardous and costly to the client. An ill-fitting wheelchair can, in fact, contribute to unnecessary fatigue, **skin breakdown**, and trunk or extremity deformity, and it can inhibit function.⁴⁹ A wheelchair is an extension of the client's body and should facilitate rather than inhibit good alignment, mobility, and function.

Wheelchair Assessment

The therapist has considerable responsibility in recommending the wheelchair appropriate to meet immediate and long-term needs. When evaluating for a wheelchair, the therapist must know the client and have a broad perspective of the client's clinical, functional, and environmental needs. Careful assessment of physical status must include the following: the specific diagnosis, the prognosis, and current and future problems (e.g., age, spasticity, loss of range of motion [ROM], muscle weakness, reduced endurance) that may affect wheelchair use. Additional client factors to be

Case Study William

William is a 17-year-old male who sustained a C6 spinal cord injury after a diving accident approximately 2 weeks ago. Sensation and motor function are absent below the level of the lesion. He is medically stable, is receiving rehabilitation services, and is referred for a wheelchair assessment. William has a halo vest for stabilization and is able to tolerate sitting upright for 1 hour before he complains of getting dizzy. He still asks the rehabilitation therapists, nurses, and his physician when he will be able to move his legs. He has been told that because he has had no return of function during the past 2 weeks, it is unlikely that he will have significant changes in his current level of motor and sensory function.

Upon discharge from the inpatient rehabilitation unit, William will be returning to his home, where he lives with his parents and younger brother. The home is two stories high, and William's bedroom is located on the second floor. A bathroom is located on the first floor.

Before his injury, William was very physically active and was on the track and field team at his high school. He was also an avid hiker and often would go camping with his family and friends. William is a high school senior and received early acceptance to a university located within 2 hours of his home. He was very excited about attending this university because of the track and field program, in addition to his interest in becoming a marine biologist. Although William's friends have come to visit him, his girlfriend of 2 years has not visited.

Critical Thinking Questions

1. How would you anticipate that William would respond to being fitted for a wheelchair? What emotional responses may be evoked in William by this experience? How could you minimize his potential distress?
2. What decisions could William make regarding selection of the wheelchair?
3. Considering William's needs across several contexts, what type of wheelchair would you recommend?
4. What client factors must be considered when a wheelchair is selected for William?

■ Box 11-1

Questions to Ask Before Making Specific Recommendations for a Wheelchair

- Who will pay for the wheelchair?
- Who will determine the preferred DME provider: the insurance company, the client, or the therapist?
- What is the specific disability?
- What is the prognosis?
- Is range of motion limited?
- Is strength or endurance limited?
- How will the client propel the chair?
- How old is the client?
- How long is the client expected to use the wheelchair?
- What was the client's lifestyle, and how has it changed?
- Is the client active or sedentary?
- How will the dimensions of the chair affect the client's ability to transfer to various surfaces?
- What is the maneuverability of the wheelchair in the client's home or in the community (e.g., entrances and egress, door width, turning radius in bathroom and hallways, floor surfaces)?
- What is the ratio of indoor to outdoor activities?
- Where will the wheelchair be primarily used—in the home, at school, at work, or in the community?
- Which mode of transportation will be used? Will the client be driving a van from the wheelchair? How will it be loaded and unloaded from the car?
- Which special needs (e.g., work heights, available assistance, accessibility of toilet facilities, parking facilities) are recognized in the work or school environment?
- Does the client participate in indoor or outdoor sports activities?
- How will the wheelchair affect the client psychologically?
- Can accessories and custom modifications be medically justified, or are they luxury items?
- What resources does the client have for equipment maintenance (e.g., self, family, caregivers)?

considered in assessment of wheelchair use are sensation, cognitive function, and visual and perceptual skills. Functional use of the wheelchair in a variety of environments must be considered. Collaboration with representatives of other disciplines treating the client is important. Box 11-1 lists questions to consider before making specific recommendations.

Before the final prescription is prepared, collected information must be analyzed for an understanding of advantages and disadvantages of recommendations based on the client's condition and how all specifics will integrate to provide an optimally effective mobility system.

To ensure that payment for the wheelchair is authorized, therapists should have an in-depth awareness of the client's insurance DME benefits and should provide documentation with thorough justification of the **medical necessity** of the wheelchair and any additional modifications. Therapists must explain clearly why particular features of a wheelchair are being recommended. They must be aware of standard vs. "up charge" items, the cost of each item, and the effects of these items on the end product.

Wheelchair Ordering Considerations

Before selecting a specific manufacturer and the wheelchair's specifications, the therapist should carefully analyze the following sequence of evaluation considerations.^{3,120,160}

Propelling the Wheelchair

The wheelchair may be propelled in a variety of ways, depending on the physical capacities of the user. If the client is capable of self-propulsion by using his or her arms on the

rear wheels of the wheelchair, sufficient and symmetric grasp, arm strength, and physical endurance may be assumed present to maneuver the chair independently over varied terrain throughout the day.¹⁶⁰ An assortment of push rims are available to facilitate self-propelling, depending on the user's arm and grip strength. A client with hemiplegia may propel a wheelchair using the extremities on the unaffected side for maneuvering. A client with tetraplegia may have functional use of only one arm and may be able to propel a one-arm drive wheelchair, or a power chair may be more appropriate. Although William, the 17-year-old who has a C6 spinal cord injury, has functional strength in both biceps, energy and potential injury in the future must be considered if he is to use only a manual wheelchair.

If independence in mobility is desired, a power wheelchair should be considered for those who have minimal or no use of the upper extremities, limited endurance, or shoulder dysfunction. Power chairs are also preferred in situations involving inaccessible outdoor terrain.¹⁶⁰ Power wheelchairs have a wide variety of features and can be programmed; driven by foot, arm, head, or neck; or pneumatically controlled (sip and puff), or even controlled by eye gaze. Given current sophisticated technology, assuming intact cognition and perception, even a person with the most severe physical limitations is capable of independently driving a power wheelchair.

If the chair is to be propelled by the caregiver, consideration must be given to ease of maneuverability, lifting, and handling, in addition to the positioning and mobility needs of the client.

Regardless of the method of propulsion, serious consideration must be given to the effect the chair has on the

client's current and future mobility and positioning needs. In addition, lifestyle and home environment, available resources such as ability to maintain the chair, transportation options, and available reimbursement sources are major determining factors. Although William is physically fit, his upper body strength has been compromised by the spinal cord injury. If he is interested in engaging in outdoor activities, he may lack the physical strength to propel a manual wheelchair on varied terrains. A powered wheelchair seemed an appropriate option for William, but the therapist also considered his previous occupations of camping and hiking when selecting a wheelchair that could potentially be used in outdoor terrain.

Rental vs. Purchase

The therapist should estimate how long the client will need the chair and whether the chair should be rented or purchased; this will affect the type of chair being considered. This decision is based on several clinical and functional issues. A rental chair is appropriate for short-term or temporary use, such as when the client's clinical picture, functional status, or body size is changing. Rental chairs may be necessary when the permanent wheelchair is being repaired. A rental wheelchair also may be useful when prognosis and expected outcome are unclear, or when the client has difficulty accepting the idea of using a wheelchair and needs to experience it initially as a temporary piece of equipment. Often the eventual functional outcome is unknown. In this case, a chair can be rented for several months until a re-evaluation determines whether a permanent chair will be necessary.³

A permanent wheelchair is indicated for the full-time user and for the client with a progressive need for a wheelchair over a long period. It may be indicated when custom features are required or when body size is changing, such as in the growing child.³

Frame Style

Once the method of propulsion and the permanence of the chair have been determined, several wheelchair frame styles are available for consideration. The frame style must be selected before specific dimensions and brand names can be determined. The therapist needs to be aware of the various features, the advantages and disadvantages of each, and the effects of these features on the client in every aspect of his or her life, from a short-term and a long-term perspective. William is still in emotional shock that he no longer has motor control of his legs and hands. These variables must be considered when William is approached about wheelchair selection. Although a power wheelchair seemed the most appropriate choice for William, the therapist was concerned about the appearance of the wheelchair. The therapist actively engaged William in making choices regarding the type, model, and options available on various wheelchairs.

Wheelchair Selection

The following questions regarding client needs should be considered carefully before the specific type of chair is determined.³

Manual vs. Electric/Power Wheelchairs

Manual Wheelchair

See [Figure 11-3, A](#).

- Does the user have sufficient strength and endurance to propel the chair at home and in the community over varied terrain?
- Does manual mobility enhance functional independence and cardiovascular conditioning of the wheelchair user?
- Will the caregiver be propelling the chair at any time?
- What will be the long-term effects of the propulsion choice?

Power Chairs

Power chair controls come in a number of designs and allow for varying degrees of customization and programming. Most power chair users drive using a joystick control mounted on the armrest. For those without upper extremity function, several other types of controls are available, such as head controls, chin drives, and breath controls (sip and puff). New technology even accommodates a client with only eye or tongue movement that can be used to operate a power wheelchair ([Figure 11-3, B](#)).

- Does the user demonstrate insufficient endurance and functional ability to propel a manual wheelchair independently?
- Does the user demonstrate progressive functional loss, making powered mobility an energy-conserving option?
- Is powered mobility needed to enhance independence at school, at work, and in the community?
- Does the user demonstrate cognitive and perceptual ability to safely operate a power-driven system?
- Does the user or caregiver demonstrate responsibility for care and maintenance of equipment?
- Is a van available for transportation?
- Is the user's home accessible for use of a power wheelchair?
- Has the user been educated regarding rear, mid, and front wheel drive systems, and has he or she been guided objectively in making the appropriate selection?

Manual Recline vs. Power Recline vs. Tilt Wheelchairs

Manual Recline Wheelchair

See [Figure 11-4, A](#).

- Is the client unable to sit upright because of hip contractures, poor balance, or fatigue?

A

B

FIGURE 11-3 Manual vs. electric wheelchair. **A**, Rigid frame chair with swing-away footrests. **B**, Power-driven wheelchair with hand control. (A, Courtesy Quickie Designs; B, courtesy Invacare Corporation.)

- Is a caregiver available to assist with weight shifts and position changes?
- Is relative ease of maintenance a concern?
- Is cost a consideration?

Power Recline vs. Tilt

See Figure 11-4, B and C.

- Does the client have the potential to operate independently?
- Are independent weight shifts and position changes indicated for skin care and increased sitting tolerance?
- Does the user demonstrate safe and independent use of controls?
- Are resources available for care and maintenance of the equipment?
- Does the user have significant spasticity that is facilitated by hip and knee extension during the recline phase?
- Does the user have hip or knee contractures that prohibit his or her ability to recline fully?
- Will a power recline or tilt decrease or make more efficient use of caregiver time?
- Will a power recline or tilt feature on the wheelchair reduce the need for transfers to the bed for catheterizations and rest periods throughout the day?
- Will the client require quick position changes in the event of hypotension and/or dysreflexia?
- Has a reimbursement source been identified for this add-on feature?

Folding vs. Rigid Manual Wheelchairs

Folding Wheelchairs

See Figure 11-5, A.

- Is the folding frame needed for transport, storage, or home accessibility?
- Which footrest style is necessary for transfers, desk clearance, and other daily living skills? Elevating footrests are available only on folding frames.
- Is the client or caregiver able to lift, load, and fit the chair into necessary vehicles?
- Equipment suppliers should have knowledge and a variety of brands available. Frame weight can range approximately from 28 to 50 lb, depending on size and accessories. Frame adjustments and custom options vary with the model.

Rigid Wheelchairs

See Figure 11-5, B.

- Does the user or caregiver have the upper extremity function and balance needed to load and unload the nonfolding frame from a vehicle if driving independently?
- Will the user benefit from the improved energy efficiency and performance of a rigid frame?

Footrest options are limited and the frame is lighter (20 to 35 lb). Features include an adjustable seat angle, rear axle, caster mount, and back height. Efficient frame design maximizes performance. Options are available for frame

A

B

C

FIGURE 11-4 Manual recline vs. power recline wheelchair. **A**, Reclining back on folding frame. **B**, Low-shear power recline with collar mount chin control on electric wheelchair. **C**, Tilt system with head control on electric wheelchair.

(A, Courtesy Quickie Designs; B and C, courtesy Luis Gonzalez.)

material composition, frame colors, and aesthetics. These chairs are usually custom ordered; availability and expertise are generally limited to custom **rehabilitation technology suppliers**.

Lightweight (Folding or Nonfolding) vs. Standard-Weight (Folding) Wheelchairs

Lightweight Wheelchairs: Under 35 Pounds

See [Figure 11-5, A](#).

- Does the user have the trunk balance and equilibrium necessary to handle a lighter frame weight?
- Does the lighter weight enhance mobility by reducing the user's fatigue?
- Will the user's ability to propel the chair or handle parts be enhanced by a lighter-weight frame?

- Are custom features (e.g., adjustable height back, seat angle, axle mount) necessary?

Standard-Weight Wheelchairs: More Than 35 Pounds

See [Figure 11-6](#).

- Does the user need the stability of a standard-weight chair?
- Does the user have the ability to propel a standard-weight chair?
- Can the caregiver manage the increased weight when loading the wheelchair and fitting into a vehicle?
- Will the increased weight of parts be unimportant during daily living skills?

Custom options are limited, and these wheelchairs are usually less expensive (except heavy-duty models required for users weighing more than 250 lb).

FIGURE 11-5 Folding vs. rigid wheelchair. **A**, Lightweight folding frame with swing-away footrests. **B**, Rigid aluminum frame with tapered front end and solid foot cradle.
(A, Courtesy Quickie Designs; B, courtesy Invacare Corporation.)

Standard Available Features vs. Custom, Top-of-the-Line Models

The price range, durability, and warranty within a specific manufacturer's model line must be considered.

Standard Available Features

- Is the chair required only for part-time use?
- Does the user have a limited life expectancy?
- Is the chair needed as a second or transportation chair, used only 10% to 20% of the time?

FIGURE 11-6 Standard folding frame (>35 lb) with swing-away footrests.
(Courtesy Everest & Jennings, Inc.)

- Will the chair be primarily for indoor or sedentary use?
- Is the user dependent on caregivers for propulsion?
- Will the chair be propelled only by the caregiver?
- Are custom features or specifications not necessary?
- Is substantial durability unimportant?

For standard wheelchairs, a limited warranty is available on the frame. These chairs may be indicated because of reimbursement limitations. Limited sizes and options and adjustability are available. These cost considerably less than custom wheelchairs.

Custom and Top-of-the-Line Models

- Will the client be a full-time user?
- Is long-term use of the wheelchair a likely prognosis?
- Will this be the primary wheelchair?
- Is the user active indoors and outdoors?
- Will this frame style improve prognosis for independent mobility?
- Is the user a growing adolescent, or does he or she have a progressive disorder requiring later modification of the chair?
- Are custom features, specifications, or positioning devices required?

Top-of-the-line wheelchair frames usually have a lifelong warranty on the frame. A variety of specifications, options, and adjustments are available. Many manufacturers will work with therapists and providers to solve a specific fitting problem. Experience is essential in ordering top-of-the-line and custom equipment.

Wheelchair Measurement Procedures

The client is measured in the style of chair and with the seat cushion that most closely resembles those being ordered. If the client will wear a brace or body jacket or will need any additional devices in the chair, these should be in place during the measurement. Observation skills are important during this process. Measurements alone should not be used. The therapist should visually assess and monitor the client's entire body position throughout the measurement process.^{3,159}

Seat Width

See Figure 11-7, A.

Objectives

1. To distribute the client's weight over the widest possible surface.
2. To keep the overall width of the chair as narrow as possible.

Measurements

Measure the individual across the widest part of the thighs or hips while the client is sitting in a chair comparable with the anticipated wheelchair.

Wheelchair Clearance

Add $\frac{1}{2}$ to 1 inch on each side of the hip or thigh measurement taken. Consider how an increase in the overall width of the chair will affect accessibility.

Checking

Place the flat palm of the hand between the client's hip or thigh and the wheelchair skirt and armrest. The wheelchair skirt is attached to the armrests in many models, and

clearance should be sufficient between the user's thigh and the skirt to avoid rubbing or pressure.

Considerations

- User's potential weight gain or loss (i.e., gender tendencies: male-abdominal weight gain vs. female-hips and buttocks)
- Accessibility of varied environments
- Overall width of wheelchair. Camber, axle mounting position, rim style, and wheel style can also affect overall wheelchair width.

Seat Depth

See Figure 11-7, B.

Objective

The objective is to distribute the body weight along the sitting surface by bearing weight along the entire length of the thigh to just behind the knee. This approach is necessary to help prevent pressure sores on the buttocks and the lower back, and to attain optimal muscle tone normalization to assist in prevention of pressure sores throughout the body.

Measurements

Measure from the base of the back (the posterior buttocks region touching the chair back) to the inside of the bent knee; the seat edge clearance needs to be 1 to 2 inches less than this measurement.

Checking

Check clearance behind the knees to prevent contact of the front edge of the seat upholstery with the popliteal space. (Consider front angle of leg-rest or foot cradle.)

Considerations

- Braces or back inserts may push the client forward.
- Postural changes may occur throughout the day from fatigue or spasticity.
- Thigh length discrepancy: the depth of the seat may be different for each leg.
- If considering a power recliner, assume that the client will slide forward slightly throughout the day, and make depth adjustments accordingly.
- Seat depth may need to be shortened to allow independent propulsion with the lower extremities.

Seat Height from Floor and Foot Adjustment

Objectives

1. To support the client's body while maintaining the thighs parallel to the floor (Figure 11-7, C).
2. To elevate the foot plates to provide ground clearance over varied surfaces and curb cuts (Figure 11-7, D).

FIGURE 11-7 Measurements for wheelchairs. A, Seat width. B, Seat depth. C, Seat height from floor. D, Footrest clearance. E, Back height. F, Armrest height.

(Adapted from Wilson A, McFarland SR: *Wheelchairs: a prescription guide*, Charlottesville, Va, 1986, Rehabilitation Press.)

Measurements

The seat height is determined by measuring from the top of the wheelchair frame supporting the seat (the post supporting the seat) to the floor, and from the client's popliteal fossa to the bottom of the heel.

Wheelchair Clearance

The client's thighs are kept parallel to the floor, so the body weight is distributed evenly along the entire depth of the seat. The lowest point of the foot plates must clear the floor by at least 2 inches.

Checking

Slip fingers under the client's thighs at the front edge of the seat upholstery. *Note:* A custom seat height may be needed to obtain footrest clearance. An inch of increased seat height raises the foot plate 1 inch.

Considerations

If the knees are too high, increased pressure at the ischial tuberosities puts the client at risk for skin breakdown and pelvic deformity. This position also impedes the client's ability to maneuver the wheelchair using the lower extremities.

Posterior **pelvic tilt** makes it difficult to shift weight forward as needed to propel the wheelchair, especially with uphill grades.

Sitting too high off the ground can impair the client's center of gravity, seat height for transfers, and visibility if driving a van from the wheelchair.

Back Height

See Figure 11-7, E.

Objective

Back support consistent with physical and functional needs must be provided. The chair back should be low enough for maximal function and high enough for maximal support.

Measurements

For full trunk support for the client, the back must be of sufficient height. Full support height is obtained by measuring from the top of the seat frame on the wheelchair (seat post) to the top of the user's shoulders. For minimum trunk support, the top of the back upholstery is below the inferior angle of the client's scapulae; this should permit free arm movement, should not irritate the skin or scapulae, and should provide good total body alignment.

Checking

Ensure that the client is not being pushed forward because the back of the chair is too high or is not leaning backward over the top of the upholstery because the back is too low.

Considerations

- Adjustable-height backs (usually offer a 4-inch range)
- Adjustable upholstery
- Lumbar support or another commercially available or custom back insert to prevent kyphosis, scoliosis, or other long-term trunk deformity

Armrest Height

See Figure 11-7, F.

Objectives

1. To maintain posture and balance.
2. To provide support and alignment for upper extremities.
3. To allow change in position by pushing down on armrests.

Measurements

With the client in a comfortable position, measure from the wheelchair seat frame (seat post) to the bottom of the user's bent elbow.

Wheelchair Clearance

The height of the top of the armrest should be 1 inch higher than the height from the seat post to the user's elbow.

Checking

The client's posture should look appropriately aligned. The shoulders should not slouch forward or be subluxed or forced into elevation when the client is in a relaxed sitting posture, with flexed elbows resting slightly forward on armrests.

Considerations

- Armrests may have other uses, such as increasing functional reach or holding a cushion in place.
- Certain styles of armrests can increase the overall width of the chair.
- Are armrests necessary?
- Is the client able to remove and replace the armrest from the chair independently?
- Review all measurements against standards for a particular model of chair.
- Manufacturers have lists of the standard dimensions available and the costs of custom modifications.

Pediatrics

The goals of pediatric wheelchair ordering, as with all wheelchair ordering, should be to obtain a proper fit and to facilitate optimal function. Rarely does a standard wheelchair meet the fitting requirements of a child. The selection of size is variable; therefore custom seating systems specific to the pediatric population are available. A secondary goal is to consider a chair that will accommodate the child's growth.

For children younger than 5 years of age, a decision must be made about whether to use a stroller base or a standard wheelchair base. Considerations include the child's ability to propel the chair relative to his or her developmental level, and the parents' preference for a stroller or a wheelchair.

Many variables must be considered when a wheelchair frame is customized. An experienced ATP or the wheelchair manufacturer should be consulted to ensure that a custom request will be filled successfully.

Bariatrics

According to the latest data from the National Center for Health Statistics, more than 30% of American adults 20 years of age and older (more than 60 million people) are obese.⁴⁷ The average wheelchair is rated to hold up to 250 pounds, and most bariatric wheelchairs can accommodate 500 pounds. It is imperative that the therapist order a wheelchair that not only meets the client's functional needs but will safely accommodate his or her weight. Utilizing a wheelchair for patients who exceed the weight limit has potential safety issues such as skin breakdown and the risk of wheelchair bending or buckling, which may cause injury to the client. Bariatric wheelchairs feature heavy duty frames, reinforced padded upholstery, and heavy duty wheels. An experienced supplier of DME should be able to guide the therapist and the client to the most appropriate and safe wheelchair.

Additional Seating and Positioning Considerations

A wheelchair evaluation is not complete until the seat cushion, the back support, and any other positioning devices as well as the integration of those parts are carefully thought out, regardless of the diagnosis. The therapist must appreciate the effect that optimal body alignment has on skin integrity, tone normalization, overall functional ability, and general well-being (Figure 11-8).³

Consider William's potential need for a wheelchair seat cushion that will distribute weight evenly and avoid excessive pressure on his ischial tuberosities while sitting. He lacks sensory awareness in the buttocks region, and that places him at risk for developing decubitus ulcers. He should develop sitting tolerance that extends beyond the current 1-hour time period to help him pursue his educational goals of attending college. An appropriate seat cushion that distributes weight evenly will help William remain seated for a longer period of time. He will also need to develop the habit of shifting his weight while seated. This can be done by having William position his arm around the upright posts of the wheelchair back and pulling his body slightly to one side and then repeating the process on the other side. This shifting of the body from side to side reduces the risk of developing decubitus ulcers.

Following are the goals of a comprehensive seating and positioning assessment.

Prevention of Deformity

Providing a symmetric base of support preserves proper skeletal alignment and discourages spinal curvature and other body deformities.

Tone Normalization

With proper body alignment, in addition to bilateral weight bearing and adaptive devices as needed, tone normalization can be maximized.

Pressure Management

Pressure sores can be caused by improper alignment and an inappropriate sitting surface. The proper seat cushion can provide comfort, assist in trunk and pelvic alignment, and create a surface that minimizes pressure, heat, moisture, and shearing—the primary causes of skin breakdown.

Promotion of Function

Pelvic and trunk stability is necessary to free the upper extremity for participation in all functional activities, including wheelchair mobility and daily living skills.

Maximum Sitting Tolerance

Wheelchair sitting tolerance will increase as support, comfort, and symmetric weight bearing are provided.

Optimal Respiratory Function

Support in an erect, well-aligned position can decrease compression of the diaphragm, thus increasing **vital capacity**.

Provision for Proper Body Alignment

Good body alignment is necessary for prevention of deformity, normalization of tone, and promotion of movement. The client should be able to propel the wheelchair and to move around within the wheelchair.

A wide variety of seating and positioning equipment is available for all levels of disability. Custom modifications are continually being designed to meet a variety of client needs. In addition, technology in this area is ever growing, as is interest in wheelchair technology as a professional specialty. However, the skill of clinicians in this field ranges from extensive to negligible. Although it is an integral aspect of any wheelchair evaluation, the scope of seating and positioning equipment is much greater than can be addressed in this chapter. The suggested reading list at the end of this chapter provides additional resources.

Accessories

Once the measurements and the need for additional positioning devices have been determined, a wide variety of accessories are available to meet a client's individual needs. It is extremely important for the therapist to understand the

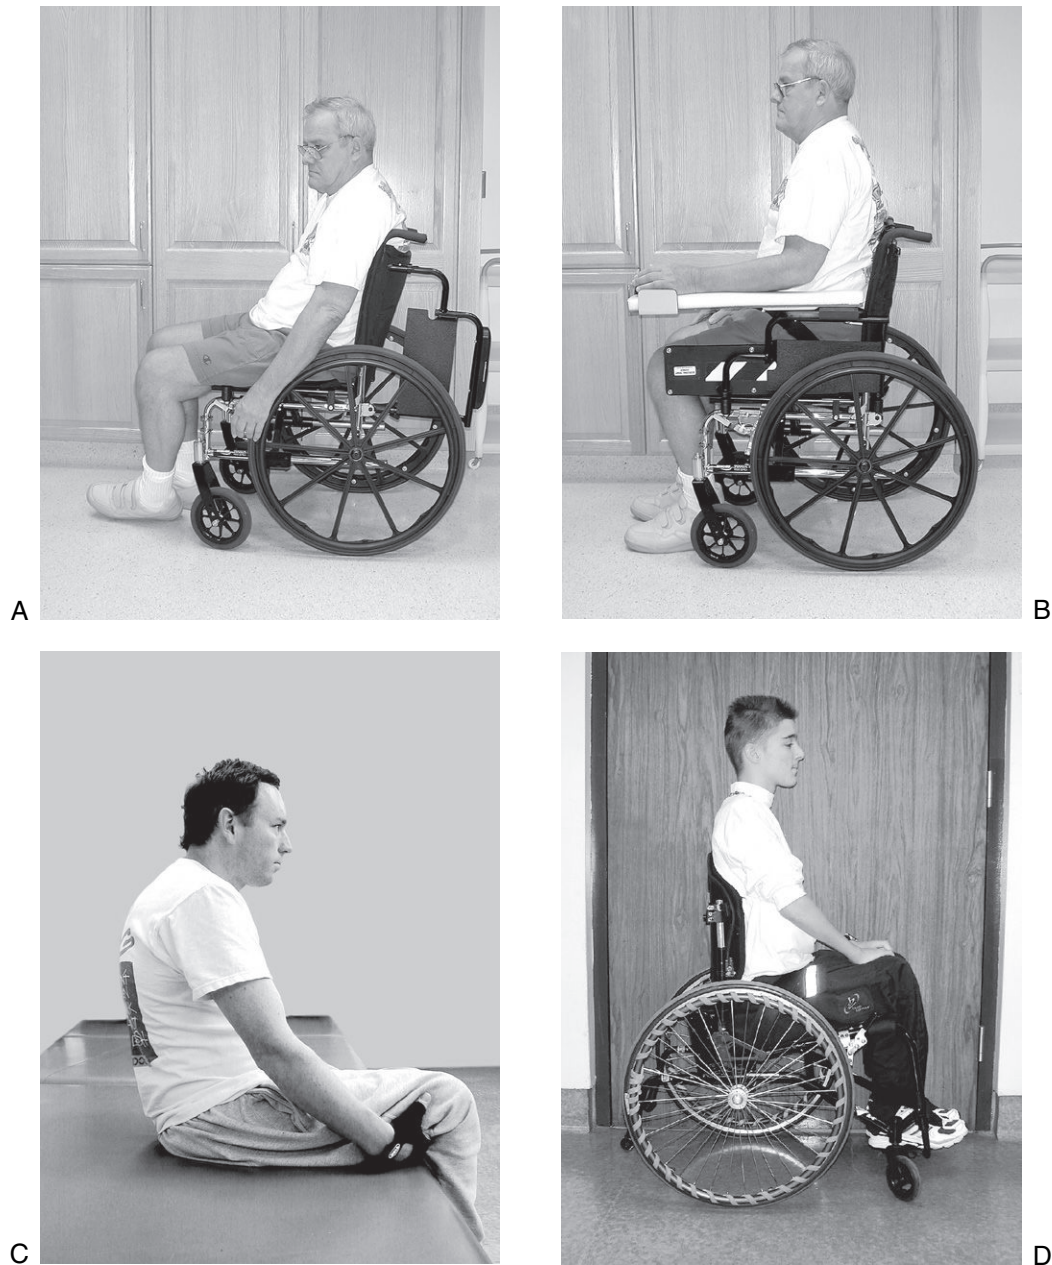

FIGURE 11-8 **A**, Client who had a stroke, seated in wheelchair. Poor positioning results in kyphotic thoracic spine, posterior pelvic tilt, and unsupported affected side. **B**, Same client now seated in wheelchair with appropriate positioning devices. Seat and back inserts facilitate upright midline position with neutral pelvic tilt and equal weight bearing throughout. **C**, Client who sustained a spinal cord injury sitting with back poorly supported results in posterior pelvic tilt, kyphotic thoracic spine, and absence of lumbar curve. **D**, Same client seated with rigid back support and pressure-relief seat cushion, resulting in erect thoracic spine, lumbar curve, and anterior tilted pelvis.

function of each accessory and how an accessory interacts with the complete design and function of the chair and with seating and positioning equipment.^{3,160}

Armrests come in fixed, flip-back, detachable, desk, standard, reclining, adjustable height, and tubular styles. The fixed armrest is a continuous part of the frame and is not detachable. It limits proximity to table, counter, and desk surfaces and prohibits side transfers. Flip-back, detachable desk, and standard-length arms are removable and allow side-approach transfers. Reclining arms are attached to the

back post and recline with the back of the chair. Tubular arms are available on lightweight frames.

Footrests may be fixed, swing-away detachable, solid cradle, and elevating. Fixed footrests are attached to the wheelchair frame and are not removable. These footrests prevent the person from getting close to counters and may make some types of transfers more difficult. Swing-away detachable footrests can be moved to the side of the chair or removed entirely. This allows a closer approach to bed, bathtub, and counters, and, when the footrests are removed,

reduces the overall wheelchair length and weight for easy loading into a car. Detachable footrests lock into place on the chair with a locking device.¹⁶⁰ A solid cradle footrest is found on rigid, lightweight chairs and is not removable. Elevating leg rests are available for clients with such conditions as lower extremity edema, blood pressure changes, and orthopedic problems.

Foot plates may have heel loops and toe straps to aid in securing the foot to the foot plate.¹⁶⁰ The angle of the footplate itself can be fixed or adjustable, raising or lowering toes relative to heels. A calf strap can be used on a solid cradle, or when additional support behind the calf is necessary. Other accessories can include seat belts, various brake styles, brake extensions, anti-tip devices, caster locks, arm supports, and head supports.

Preparing the Justification/ Prescription

Once specific measurements and the need for modifications and accessories have been determined, the wheelchair prescription must be completed. It should be concise and specific so that everything requested can be accurately interpreted by the DME supplier, who will be submitting a sales contract for payment authorization. Before-and-after pictures can be helpful to illustrate medical necessity. The requirements for payment authorization from a particular reimbursement source must be known, so that medical necessity can be demonstrated. The therapist must be aware of the cost of every item being requested and must provide a reason and justification for each item. Payment may be denied if clear reasons are not given to substantiate the necessity for every item and modification requested.

Before the wheelchair is delivered to the client, the therapist should check the chair vs. the specific prescription and should ensure that all specifications and accessories are correct. When a custom chair has been ordered, the client should be fitted by the ordering therapist to ensure that the chair fits, and that it provides all the elements expected when the prescription was generated.

Wheelchair Safety

Wheelchair parts tend to loosen over time and should be inspected and tightened on a regular basis.

Elements of safety for the wheelchair user and the caregiver are as follows:

1. Brakes should be locked during all transfers.
2. The client should never weight bear or stand on the foot plates, which are placed in the “up” position during most transfers.
3. In most transfers, it is an advantage to have footrests removed or swung away if possible.
4. If a caregiver is pushing the chair, he or she should be sure that the client’s elbows are not protruding from

the armrests and that the client’s hands are not on the hand rims. If approaching from behind to assist in moving the wheelchair, the caregiver should inform the client of this intent and should check the position of the client’s feet and arms before proceeding.

5. To push the client up a ramp, he or she should move in a normal, forward direction. If the ramp is negotiated independently, the client should lean slightly forward while propelling the wheelchair up the incline.¹⁶¹
6. To push the client down a ramp, the caretaker should tilt the wheelchair backward by pushing his or her foot down on the anti-tippers to its balance position, which is a tilt of approximately 30 degrees. Then the caregiver should ease the wheelchair down the ramp in a forward direction, while maintaining the chair in its balance position. The caregiver should keep his or her knees slightly bent and the back straight.¹⁶¹ The caregiver may also move down the ramp backward while the client maintains some control of the large wheels to prevent rapid backward motion. This approach is useful if the grade is relatively steep. Ramps with only a slight grade can be managed in a forward direction if the caregiver maintains grasp and pull on the hand grips, and the client again maintains some control of the big wheels to prevent rapid forward motion. If the ramp is negotiated independently, the client should move down the ramp facing forward, while leaning backward slightly and maintaining control of speed by grasping the hand rims. The client can descend a steep grade by traversing the ramp slightly back and forth to slow the chair. Push gloves may be helpful to reduce the effects of friction.¹⁶¹
7. A caregiver can manage ascending curbs by approaching them forward, tipping the wheelchair back, and pushing the foot down on the anti-tipper levers, thus lifting the front casters onto the curb and pushing forward. The large wheels then are in contact with the curb and roll on with ease as the chair is lifted slightly onto the curb.
8. The curb should be descended using a backward approach. A caregiver can move himself or herself and the chair around as the curb is approached and can pull the wheelchair to the edge of the curb. Standing below the curb, the caregiver can guide the large wheels off the curb by slowly pulling the wheelchair backward until it begins to descend. After the large wheels are safely on the street surface, the assistant can tilt the chair back to clear the casters, move backward, lower the casters to the street surface, and turn around.¹⁶¹

With good strength and coordination, many clients can be trained to manage curbs independently. To mount and descend a curb, the client must have good bilateral grip,

arm strength, and balance. To mount the curb, the client tilts the chair onto the rear wheels and pushes forward until the front wheels hang over the curb, then lowers them gently. The client then leans forward and forcefully pushes forward on the hand rims to bring the rear wheels up on the pavement. To descend a curb, the client should lean forward and push slowly backward until the rear and then the front wheels roll down the curb.⁴³

The ability to lift the front casters off the ground and balance on the rear wheels (“pop a wheelie”) is a beneficial skill that expands the client’s independence in the community with curb management, and in rural settings with movement over grassy, sandy, or rough terrain. The chair will have to be properly adjusted so that the axle is not too far forward, which makes the wheelchair tip over backward too easily. Clients who have good grip, arm strength, and balance usually can master this skill and perform safely. The technique involves being able to tilt the chair on the rear wheels, balance the chair on the rear wheels, and move and turn the chair on the rear wheels. Wheelies make it possible to wheel up or down (jump) curbs. The client should not attempt to perform these maneuvers without instruction and training in the proper techniques, which are beyond the scope of this chapter. Specific instructions on teaching these skills can be found in the sources cited at the end of the chapter.⁴³

Transfer Techniques

Transferring is the movement of a client from one surface to another. This process includes the sequence of events that must occur both before and after the move, such as the pre-transfer sequence of bed mobility and the post-transfer phase of wheelchair positioning. If it is assumed that a client has some physical or cognitive limitations, it will be necessary for the therapist to assist in or supervise a transfer. Many therapists are unsure of the transfer type and technique to employ or feel perplexed when a particular technique does not succeed with the client. Each client, therapist, and situation is different. This chapter does not include an outline of all techniques but presents the basic techniques with generalized principles. Each transfer must be adapted for the particular client and his or her needs. Discussion in this chapter includes directions for some transfer techniques that are most commonly employed in practice. These techniques include the stand pivot, the bent pivot, and one-person and two-person dependent transfers.

Preliminary Concepts

The therapist must be aware of the following concepts when selecting and carrying out transfer techniques to ensure safety for the client and self:

1. The client’s status, especially his or her physical, cognitive, perceptual, and behavioral abilities and limitations.

2. His or her own physical abilities and limitations and whether he or she can communicate clear, sequential instructions to the client (and if necessary to the long-term caregiver of the client).
3. The use of correct moving and lifting techniques.

Guidelines for Using Proper Mechanics

The therapist should be aware of the following principles of basic body mechanics⁴⁴:

1. Get close to the client or move the client close to you.
2. Position your body to face the client (face head on).
3. Bend the knees; use your legs, not your back.
4. Keep a neutral spine (not a bent or arched back).
5. Keep a wide base of support.
6. Keep your heels down.
7. Don’t tackle more than you can handle; ask for help.
8. Don’t combine movements. Avoid rotating at the same time as bending forward or backward.

The therapist should consider the following questions before performing a transfer:

1. What medical precautions affect the client’s mobility or method of transfer?
2. Can the transfer be performed safely by one person, or is assistance required?
3. Has enough time been allotted for safe execution of a transfer? Are you in a hurry?
4. Does the client understand what is going to happen? If not, does he or she demonstrate fear or confusion? Are you prepared for this limitation?
5. Is the equipment (wheelchair, bed) that the client is being transferred to and from in good working order and in a locked position?
6. What is the height of the bed (or surface) in relation to the wheelchair? Can the heights be adjusted so that they are similar? Transferring downhill is easier than uphill.
7. Is all equipment placed in the correct position?
8. Are all unnecessary bedding and equipment (e.g., footrests, armrests) moved out of the way so that you are working without obstruction?
9. Is the client dressed properly in case you need to use a waistband to assist? If not, do you need a transfer belt or other assistance?
10. What are the other components of the transfer, such as leg management and bed mobility?

The therapist should be familiar with as many types of transfers as possible, so that each situation can be resolved as it arises.

Many classifications of transfers exist, based on the extent of therapist participation. Classifications range from dependent, in which the client is unable to participate and the therapist moves the client, to independent, in which the client moves independently while the therapist merely

supervises, observes, or provides input for appropriate technique related to the client's disabling condition.

Before attempting to move a client, the therapist must understand the biomechanics of movement and the effect the client's center of **positioning mass** has on transfers.

Principles of Body Positioning

Pelvic Tilt

Generally, after the acute onset of a disability or prolonged time spent in bed, clients assume a posterior pelvic tilt (i.e., a slouched position with lumbar flexion). In turn, this posture moves the center of mass back toward the buttocks. The therapist may need to verbally cue or manually assist the client into a neutral or slightly anterior pelvic tilt position to move the center of mass forward over the center of the client's body and over the feet in preparation for the transfer.¹³²

Trunk Alignment

It may be observed that the client's trunk alignment is shifted to the right or the left side. If the therapist assists in moving the client while the client's weight is shifted to one side, this movement could throw the client and the therapist off balance. The client may need verbal cues or physical assistance to come to and maintain a midline trunk position before and during the transfer.

Weight Shifting

Transfer is initiated by shifting the client's weight forward, thus removing weight from the buttocks. This movement allows the client to stand, partially stand, or be pivoted by the therapist. This step must be performed regardless of the type of transfer.

Lower Extremity Positioning

The client's feet must be placed firmly on the floor with ankles stabilized and with knees aligned at 90 degrees of flexion over the feet. This position allows the weight to be shifted easily onto and over the feet. Heels should be pointing toward the surface to which the client is transferring. The client should be barefoot or should have shoes on to prevent slipping out of position. Shoes with proper ankle support are beneficial for patients who have weakness/instability in the ankles/feet. The feet can easily pivot in this position, and the risk of twisting or injuring an ankle or knee is minimized.

Upper Extremity Positioning

The client's arms must be in a safe position or in a position in which he or she can assist in the transfer. If one or both of the upper extremities are nonfunctional, the arms should be placed in a safe position that will not be in the way during the transfer (e.g., in the client's lap). If the client has partial or full movement, motor control, or strength, he or she can assist in the transfer by reaching toward the surface

to be reached or by pushing off from the surface to be left. The decision to request the client to use the arms during the transfer is based on the therapist's prior knowledge of the client's motor function. The client should be encouraged to not reach or grab for the therapist during the transfer, as this could throw balance off.

Preparing Equipment and Client for Transfer

The transfer process includes setting up the environment, positioning the wheelchair, and helping the client into a pre-transfer position. The following is a general overview of these steps.

Positioning the Wheelchair

1. Place the wheelchair at approximately a 0- to 30-degree angle to the surface to which the client is transferring. **The angle depends on the type of transfer and the client's level of assist.**
2. Lock the brakes on the wheelchair and the bed.
3. Place both of the client's feet firmly on the floor, hip width apart, with knees over the feet.
4. Remove the wheelchair armrest closer to the bed.
5. Remove the wheelchair pelvic seat belt.
6. Remove the wheelchair chest belt and trunk or lateral supports if present.

Bed Mobility in Preparation for Transfer

Rolling the Client Who Has Hemiplegia

1. Before rolling the client, you may need to put your hand under the client's scapula on the weaker side and gently mobilize it forward (into protraction) to prevent the client from rolling onto the shoulder, potentially causing pain and injury.
2. Assist the client in clasping the strong hand around the wrist of the weak arm, and lift the upper extremities upward toward the ceiling.
3. Assist the client in flexing his or her knees.
4. You may assist the client to roll onto his or her side by moving first the arms toward the side, then the legs, and finally by placing one of the therapist's hands at the scapular area and the other therapist's hand at the hip, guiding the roll.

Side-Lying to Sit Up at the Edge of the Bed

1. Bring the client's feet off the edge of the bed.
2. Stabilize the client's lower extremities with your knees.
3. Shift the client's body to an upright sitting position.
4. Place the client's hands on the bed at the sides of his or her body to help maintain balance.

Scotching to the Edge of the Bed

When working with a client who has sustained a stroke or a traumatic brain injury, walk the client's hips toward the edge of the bed. Shift the client's weight to the less affected

or unaffected side, position your hand behind the opposite buttock, and guide the client forward. Then shift the client's weight to the more affected side, and repeat the procedure if necessary. Move forward until the client's feet are flat on the floor.

In the case of an individual with spinal cord injury, grasp the client's legs from behind the knees and gently pull the client forward, placing the client's feet firmly on the floor and making sure that the ankles are in a neutral position.

Stand Pivot Transfers

The standing pivot transfer requires the client to be able to come to a standing position and pivot on both feet. It is most commonly used with clients who have hemiplegia, hemiparesis, or general loss of strength or balance. If the client has significant hemiparesis, stand pivot transfers encourage the less affected or the unaffected side to accommodate most of the body weight and may put the more affected limb (ankle) at risk while pivoting.

Wheelchair-to-Bed or -Mat Transfer

1. Facilitate the client's scoot to the edge of the surface, and put his or her feet flat on the floor. The client's heels should be pointed toward the surface to which the client is transferring. The feet should not be perpendicular to the transfer surface, but the heel should be angled toward the surface.
2. Stand on the client's affected side with your hands on the client's scapulae or around the client's trunk, waist, or hips. Stabilize the client's involved foot and knee with your own foot and knee. Provide assistance by guiding the client forward as the buttocks are lifted up from the present surface and toward the transfer surface (Figure 11-9, A).
3. The client may reach toward the surface to which he or she is transferring or may push off the surface from which he or she is transferring (Figure 11-9, B).
4. Guide the client toward the transfer surface, and gently help him or her down to a sitting position (Figure 11-9, C).

Variations: Stand Pivot and/or Stand/Step Transfer

A stand pivot and/or stand/step transfer is generally used when a client can take small steps toward the surface goal and not just pivot toward the transfer surface. The therapist's intervention may range from physical assistance to accommodation for potential loss of balance to facilitation of near normal movement, equal weight bearing, and maintenance of appropriate posture for clients with hemiplegia or hemiparesis. If a client demonstrates impaired cognition or a behavior deficit, including impulsiveness and poor safety judgment, the therapist may need to provide verbal cues or physical guidance.

Sliding Board Transfers

Sliding board transfers are best used with those who cannot bear weight on the lower extremities and who have paralysis, weakness, or poor endurance in their upper extremities. If the client is going to assist the caregiver in this transfer, the client should have good upper extremity strength. This transfer is most often employed with persons who have lower extremity amputations, individuals with spinal cord injuries, and bariatric clients.

Method

See Figure 11-10.

1. Position and set up the wheelchair as previously outlined.
2. Lift the leg closer to the transfer surface and place the board under this leg, at midthigh between the buttocks and the knee, angled toward the opposite hip. The board must be firmly under the thigh and firmly on the surface to which the client is transferring.
3. Block the client's knees with your own knees.
4. Instruct the client to place one hand toward the edge of the board and the other hand on the wheelchair seat.
5. Instruct the client to lean forward and slightly away from the transferring surface.
6. The client should transfer his or her upper body weight in the direction opposite to which he or she is going. The client should use both arms to lift or slide the buttocks along the board.
7. Assist the client where needed to shift weight and support the trunk while moving to the intended surface.

Bent Pivot Transfer: Bed to Wheelchair

The bent pivot transfer is used when the client cannot initiate or maintain a standing position. A therapist often prefers to keep a client in the bent knee position to maintain equal weight bearing, provide optimal trunk and lower extremity support, and perform a safer and easier therapist-assisted transfer.

Procedure

1. Assist the client to scoot to the edge of the bed until both of the client's feet are flat on the floor. Grasp the client around the waist, trunk, or hips, or even under the buttocks, if a moderate or maximal amount of assistance is required.
2. Facilitate the client's trunk into a midline position.
3. Shift the weight forward from the buttocks toward and over the client's feet (Figure 11-11, A).

FIGURE 11-9 Standing pivot transfer; wheelchair to bed, assisted. **A**, Therapist stands on client's affected side and stabilizes client's foot and knee. She assists by guiding client forward and initiates lifting the buttocks up. **B**, Client reaches toward transfer surface. **C**, Therapist guides the client toward transfer surface.

(Courtesy Luis Gonzalez.)

4. Have the client reach toward the surface he or she is transferring to or push from the surface he or she is transferring from (Figure 11-11, *B*).
5. Provide assistance by guiding and pivoting the client around toward the transfer surface (Figure 11-11, *C*).

Depending on the amount of assistance required, the pivoting portion can be done in two or three steps, with the therapist repositioning himself or herself and the client's

lower extremities between steps. The therapist has a variety of choices regarding where to hold or grasp the client during the bent pivot transfer, depending on the weight and height of the client in relation to the therapist and the client's ability to assist in the transfer. Variations include using both hands and arms at the waist or trunk, or one or both hands under the buttocks. The therapist never grasps under the client's weak arm or grasps the weak arm—an action that could cause significant injury because of weak musculature

FIGURE 11-10 Positioning sliding board. Lift leg closest to transfer surface. Place board midhigh between buttocks and knee, angled toward opposite hip.
(Courtesy Luis Gonzalez.)

FIGURE 11-11 Bent pivot transfer; bed to wheelchair. **A**, Therapist grasps client around trunk and assists in shifting client's weight forward over feet. **B**, Client reaches toward wheelchair. **C**, Therapist assists client down toward sitting position.
(Courtesy Luis Gonzalez.)

and poor stability around the shoulder girdle. The choice is made with consideration of proper body mechanics. Trial and error in technique is advised to allow for optimal facilitation of client independence and safety, and the therapist's proper body mechanics.

Dependent Transfers

The dependent transfer is designed for use with the client who has minimal to no functional ability. If this transfer is performed incorrectly, it is potentially hazardous for

therapist and client. This transfer should be practiced with able-bodied persons and should be used first with the client only when another person is available to assist.⁴

The purpose of the dependent transfer is to move the client from surface to surface. The requirements are that the client be cooperative and willing to follow instructions. The therapist should be keenly aware of correct body mechanics and his or her own physical limitations. With heavy clients, it is always best to use the two-person transfer, or at least to have a second person available to spot the transfer.

One-Person Dependent Sliding Board Transfer

See [Figure 11-12](#).

The procedure for transferring the client from wheelchair to bed is as follows:

1. Set up the wheelchair and bed as described previously.
2. Position the client's feet together on the floor, directly under the knees, and swing the outside footrest away.
3. Place a sliding board under the client's inside thigh, midway between the buttocks and the knee, to form a bridge from the bed to the wheelchair. The sliding board is angled toward the client's opposite hip.

FIGURE 11-12, cont'd E, Therapist pivots with client and moves client onto sliding board. F, Client is stabilized on the bed. (Courtesy Luis Gonzales.)

4. Stabilize the client's feet by placing your feet laterally around the client's feet.
5. Stabilize the client's knees by placing your own knees firmly against the anterolateral aspect of the client's knees (Figure 11-12, B).
6. Facilitate the client's lean over the knees by guiding him or her forward from the shoulders. The client's head and trunk should lean opposite the direction of the transfer. The client's hands can rest on the lap.
7. Reach under the client's outside arm and grasp the waistband of the trousers or under the buttock. On the other side, reach over the client's back and grasp the waistband or under the buttock (Figure 11-12, C).
8. After your arms are positioned correctly, lock them to stabilize the client's trunk. Keep your knees slightly bent and brace them firmly against the client's knees.
9. Gently rock with the client to gain some momentum, and prepare to move after the count of three. Count to three aloud with the client. On three, holding your knees tightly against the client's knees, transfer the client's weight over his or her feet. You must keep your back straight and your knees bent to maintain good body mechanics (Figure 11-12, D).
10. Pivot with the client and move him or her onto the sliding board (Figure 11-12, E). Reposition yourself and the client's feet and repeat the pivot until the client is firmly seated on the bed surface, perpendicular to the edge of the mattress and as far back as possible. This step usually can be achieved in two or three stages (Figure 11-12, F).
11. You can secure the client onto the bed by easing him or her against the back of an elevated bed or onto the

mattress in a side-lying position, then by lifting the legs onto the bed.

The one-person dependent sliding board transfer can be adapted to move the client to other surfaces. It should be attempted only when therapist and client feel secure with the wheelchair-to-bed transfer.

Two-Person Dependent Transfers

Bent Pivot: With or Without a Sliding Board Bed to Wheelchair

A bent pivot transfer is used to allow increased therapist interaction and support. It provides the therapist with greater control of the client's trunk and buttocks during the transfer. This technique can also be employed during a two-person dependent transfer. It is often used with neurologically involved clients because trunk flexion and equal weight bearing are often desirable with this diagnosis. The steps in this two-person procedure are as follows:

1. Set up the wheelchair and bed as described previously.
2. One therapist assumes a position in front of the client and the other in back.
3. The therapist in front assists in walking the client's hips forward until the feet are flat on the floor.
4. The same therapist stabilizes the client's knees and feet by placing his or her knees and feet lateral to each of the client's.
5. The therapist in back positions himself or herself squarely behind the client's buttocks, grasping the client's waistband, grasping the sides of the client's

FIGURE 11-13 Two-person dependent transfer, bed to wheelchair. **A**, One therapist positions self in front of client, blocking feet and knees. The therapist in back positions self behind client's buttocks and assists by lifting. **B**, Person in front rocks client forward and unweights buttocks as the back therapist shifts buttocks toward wheelchair. **C**, Both therapists position client in upright, midline position in wheelchair. Seat belt is secured and positioning devices are added.

(Courtesy Luis Gonzales.)

pants, or placing his or her hands under the buttocks. Maintain proper body mechanics (Figure 11-13, *A*).

6. The therapist in front moves the client's trunk into a midline position, grasps the client around the back of the shoulders, waist, or hips, and guides the client to lean forward and shift his or her weight forward, over the feet and off the buttocks. The client's head and trunk should lean in the direction opposite the transfer. The client's hands can rest on the lap (Figure 11-13, *B*).
7. As the therapist in front shifts the client's weight forward, the therapist in back shifts the client's buttocks in the direction of the transfer. This can be

done in two or three steps, making sure the client's buttocks land on a safe, solid surface. The therapists reposition themselves and the client to maintain safe and proper body mechanics (Figure 11-13, *C*).

8. The therapists should be sure they coordinate the time of the transfer with the client and one another by counting to three aloud and instructing the team to initiate the transfer on three.
9. Transfer or gait belts may be employed to offer a place to grasp while assisting the client in a transfer. The belt is placed securely around the waist and often is utilized instead of the client's waistband. The belt should not be allowed to slide up the client's trunk because leverage will be compromised.

Mechanical Lift Transfers

Some clients, because of body size, degree of disability, or the health and well-being of the caregiver, require the use of a mechanical lift. A variety of mechanical lifting devices can be used to transfer clients of any weight (Figure 11-14). A properly trained caregiver, even one who is considerably smaller than the client, can learn to use the mechanical lift safely and independently.¹⁶¹ The client's physical size, the environment in which the lift will be used, and the uses to which the lift will be put must be considered to order the appropriate mechanical lift. The client and caregiver should demonstrate safe use of the lift for the therapist before the therapist prescribes it.

Transfers to Household Surfaces

Sofa or Chair

See Figure 11-15.

Wheelchair-to-sofa and wheelchair-to-chair transfers are similar to wheelchair-to-bed transfers; however, a few unique concerns should be assessed. The therapist and the client need to be aware that the chair may be light and not as stable as a bed or wheelchair. When transferring to the chair, the client must be instructed to reach for the seat of the chair. The client should not reach for the armrest or the back of the chair because this action may cause the chair to tip over. When moving from a chair to the wheelchair, the

client should use a hand to push off from the seat of the chair as he or she begins to stand. Standing from a chair is often more difficult if the chair is low or the seat cushions are soft. Dense cushions may be added to increase height and provide a firm surface to which to transfer.

Toilet

In general, wheelchair-to-toilet transfers are difficult because of the confined space in most bathrooms, the height of the toilet, and the instability and lack of support of a toilet seat. The therapist and client should attempt to position the wheelchair next to or at an appropriate angle to the toilet. The therapist should analyze the space around the toilet and wheelchair to ensure that no obstacles are present. Adaptive devices such as grab bars and raised toilet seats can be added to enhance the client's independence during this transfer. (Raised toilet seats are poorly secured to toilets and may be unsafe for some clients.) The client can use these devices for support during transfers and to maintain a level surface to which to transfer.

Bathtub

The OT should be cautious when assessing or teaching bathtub transfers because the bathtub is considered one of the most hazardous areas of the home. Transfers from the wheelchair to the bottom of the bathtub are extremely difficult and are used with clients who have good bilateral strength and motor control of the upper extremities (e.g.,

FIGURE 11-14 A, Traditional boom-style mechanical lift. B, Client lift useful in transferring individuals with spinal cord injury. (A, Courtesy Trans-Aid Lifts, Sunrise Medical; B, courtesy EZ-Pivot, Rand-Scott.)

Continued

FIGURE 11-14, cont'd

FIGURE 11-15 Client who sustained a stroke in midtransfer reaches for seat of chair, pivots, and lowers body to sitting. (Courtesy Luis Gonzales.)

clients with paraplegia and lower extremity amputation). A commercially produced bath bench or bath chair or a well-secured straight-back chair is commonly used by therapists for seated bathing. Therefore, whether a standing pivot, bent pivot, or sliding board transfer is performed, the technique is similar to a wheelchair-to-chair transfer. However, the transfer may be complicated by the confined space, the slick bathtub surfaces, and the bathtub wall between the wheelchair and the bathtub seat.

If a standing pivot transfer is employed, it is recommended that the locked wheelchair be placed at a 45-degree angle to the bathtub if possible. The client should stand, pivot, sit on the bathtub chair, and then place the lower extremities into the bathtub.

If a bent pivot or sliding board transfer is used, the wheelchair is placed next to the bathtub with the armrest removed. The transfer tub bench may be used and removes the need for a sliding board. This approach allows the wheelchair to be placed right next to the bench, which permits safe and easy transfer of the buttocks to the seat. Then the lower extremities can be assisted into the bathtub.

In general, the client may exit by first placing one foot securely outside the bathtub on a nonskid floor surface and then performing a standing or seated transfer back to the

FIGURE 11-16 Safety Sure Transfer Sling fastened around the client's waist and lower back for support. (Courtesy Mobility Transfer Systems, Inc.)

wheelchair. Often the client's buttocks may be bare; therefore a pillowcase may be placed over the sliding board, or a Safety Sure Transfer Sling (The Wright Stuff Inc., Crystal Springs, Miss) (Figure 11-16) may be utilized for safe transfers for bathing.

Car Transfers

A car transfer is often the most challenging for therapists because it involves trial-and-error methods to develop a technique that is safe and easy for the client and caregiver to carry out. The therapist often uses the client's existing transfer technique. The client's size, degree of disability, and vehicle style (two-door vs. four-door) must be considered. These factors will affect level of independence and may necessitate a change in the usual technique to allow a safe and easy transfer.

In general, it is difficult to get a wheelchair close enough to the car seat, especially with four-door vehicles. The following are some additional considerations when making wheelchair-to-car transfers:

1. Car seats are often much lower than the standard wheelchair seat height, which makes the uneven transfer much more difficult, especially from the car seat to the wheelchair.
2. Occasionally, clients have orthopedic injuries that necessitate the use of a brace such as a halo body jacket or a lower extremity cast or splint. The therapist often must alter the technique (e.g., recline the car seat) to accommodate these devices.

3. The therapist may suggest the use of an extra-long sliding board for this transfer to compensate for the large gap between transfer surfaces.
4. Because uphill transfers are difficult and the level of assistance may increase for this transfer, the therapist may choose a two-person assist instead of a one-person assist transfer to ensure a safe and smooth technique.

Summary

A wheelchair that fits well and can be managed safely and easily by its user and caregiver is one of the most important factors in the client's ability to perform ADLs with maximal independence.¹⁵⁹ All wheelchair users must learn the capabilities and limitations of the wheelchair and safe methods of performing all self-care and mobility skills. If a caregiver is available, he or she needs to be thoroughly familiar with safe and correct techniques of handling the wheelchair, the positioning equipment, and the client.

Transfer skills are among the most important activities that must be mastered by the wheelchair user. The ability to transfer increases the possibility of mobility and travel. However, transfers can be hazardous. Safe methods must be learned and followed.¹⁶¹ Several basic transfer techniques are outlined in this chapter. Additional methods and more detailed training and instructions are available, as discussed previously.

Many wheelchair users with exceptional abilities have developed unique methods of wheelchair management. Although such innovative approaches may work well for the person who has devised and mastered them, they cannot be considered basic procedures that everyone can learn.⁶¹

SECTION 3 | Transportation, Community Mobility, and Driving Assessment

*ANA VERRAN with contributions from
SUSAN M. LILLIE*

Competence in community mobility is an important component of quality of life throughout the lifespan.^{21,40} Community mobility can be accomplished in many ways, including walking, using a bicycle or a powered mobility device, riding as a passenger, driving oneself, or using public transportation.¹⁶⁴ It is an area of occupation that affects all areas of practice and is considered an instrumental ADL under the Occupational Therapy Practice Framework, 2nd edition (OTPF-2).¹³ Community mobility can be a means to an occupation (walking or driving to work) or an occupation in and of itself (a leisurely stroll or scenic drive).

The potential for engagement in areas of occupation and community mobility are closely linked.⁵⁴ OTs understand that community mobility is critical for accomplishing

Threaded Case Study Jacqueline, Part 1

Jacqueline is a 67-year-old retiree who has had increased difficulty in her ADLs because of painful arthritis in her neck, hands, back, hips, knees, and ankles. She is 5 feet, 6 inches tall, weighs 138 lb, and drives a 20-year-old sedan, which is meticulously maintained. Her husband has diabetes and no longer drives because of peripheral neuropathies in his legs. He is 6 feet tall and weighs 220 lb. Her role has dramatically changed; she was primarily the passenger and navigator until 1 year ago, when her husband ceased driving at the direction of his physician. She then assumed the primary role for transportation and driving, including assisting her husband with his wheelchair and car transfers.

Her doctor referred her to OT to increase independence with ADLs. She completed four visits on an outpatient basis. The therapist worked with her in the kitchen and recommended larger grip kitchen utensils to facilitate performance in meal preparation. One day, she escorted Jacqueline to her car to assess car transfers and noted difficulty in several areas: she had difficulty loading her husband's manual wheelchair, managing the key in the door, and opening the car door. Jacqueline doesn't mind driving, "although it can be painful," she told her therapist. On bad days, she doesn't drive at all.

Jacqueline is in fine health, other than the limitations posed by her arthritis. During therapy sessions, she mentioned that she feels fatigued from so much driving. She takes herself and her husband to all doctor appointments, to the pharmacy for medicines, and to church, and she maintains their home and cares for her disabled husband. She stated that she rarely participates in her hobby of scrapbooking anymore because of fatigue and lack of time. She is worried about what the future will bring because their two adult children live out-of-state, 500 miles away.

Critical Thinking Questions

1. What areas of Jacqueline's community mobility are appropriate for OT intervention?
2. Upon analysis of the task of driving relative to her diagnosis, what client factors can be predicted as needing assessment and intervention?
3. What adaptations or recommendations can Jacqueline and her therapist consider to improve mobility for her and her husband?

necessary activities and enabling those that maintain social connectedness.¹⁶⁴ In the United States, community mobility, and the subset of driving in particular, is often viewed as synonymous with independence.⁶⁷ Conversely, limitations in community mobility and loss of a driver's license can negatively impact autonomy and feelings of well-being. Lack of transportation to engage in occupations such as grocery shopping, going to medical appointments, and attending religious and/or recreation events can result in

diminished social participation.⁷⁹ Transportation problems are often cited as a primary barrier among individuals with disabilities.¹⁰⁰ Also, older adults faced with driving cessation risk depression¹²⁵ and entry into long-term care,⁷⁶ and have increased self-perceptions of disability.⁹¹

The Role of Occupational Therapy

The OT is ideally suited to identify when community mobility occupations require assessment and intervention.^{89,95} OT practitioners understand the interplay between engagement in occupation, the existence or lack of mobility options, and physical and mental health. Knowledge in this area makes the profession relevant to clients, the community, and public and private entities.¹⁵ To develop treatment plans, therapists analyze performance skills and patterns, contexts, activity demands, and client body functions and structures involved in driving and community mobility¹³ (Figure 11-17). Under this framework, OTs are concerned with the community mobility needs of clients with varying disabilities at all stages of life. Service recipients could be as diverse as a toddler with cerebral palsy, an adolescent with Asperger’s syndrome, a young adult with a spinal cord injury, and a senior citizen with dementia.¹⁵

OT services are directly related to a client’s mobility concerns and are as varied as clients and the occupations in which they engage. They can address various aspects of passenger safety, walking, biking, and use of mass transit. Interventions may also involve training in preparation to acquire

a first driver’s license, evaluation of experienced drivers with age-related changes that interfere with driving, and exploration of alternative transportation options for those people who must temporarily discontinue driving.¹⁵ Although clients are often individual persons, organizations or populations may also benefit from OT services.¹⁵ Examples of services that might be provided to organizations include modification of the paratransit eligibility evaluation for a transit company seeking to increase ridership of disabled persons, and training of drivers and bus aides for a school system seeking to improve the safety of student passengers with special needs. Services to populations may include collaboration with municipal planning organizations to promote roadway design, bike lanes, and pedestrian paths to support **older drivers** and persons using other modes of transportation.^{15,16}

The skills and training necessary to ask basic questions about community mobility issues are possessed by all OT practitioners.¹⁵ They have in common the goals of supporting participation in the community; optimizing independence in community mobility; and reducing crashes, injuries, and fatalities. However, the depth at which the individual therapist addresses community mobility issues with clients depends on his or her level of experience and the specialized training that he or she has received.^{40,59,121} Occupational therapy practitioners with specialty training and advanced certification may offer a focused approach in which driving or community mobility is the primary goal.¹³⁹ A generalist OT practitioner may address driving and

FIGURE 11-17 Community mobility in this context includes pedestrian and driver issues. The “Senior Citizen X-ing” sign reflects growing awareness of the needs of the aging population.

community mobility as part of a larger agenda to optimize occupational engagement.¹⁵

The case study at the beginning of this section illustrates how the therapist identified several areas in the client's situation that required intervention and were within her expertise and competence of training. The therapist understood that as older drivers begin to sustain more health problems, they are more likely to interact with OTs, regardless of whether the therapist specializes in driver rehabilitation.¹⁰² Although the OT working with Jacqueline did not specialize in driving, she was able to provide intervention by focusing on community mobility in a wider fashion. To elicit additional information, she explored the report that Jacqueline was sometimes unable to drive because of arthritic flare-ups. She kept in mind that early discussions about alternative transportation modes enable individuals and their families to initiate the process of considering appropriate resources and to begin contingency planning before a transportation crisis occurs.⁷ An intervention for alternative transportation was developed as a result of this conversation. As it turned out, Jacqueline qualified for alternate transportation systems but was unaware of it. The therapist was able to direct her to the appropriate resource and to assist in developing a comprehensive transportation plan. After completing the application process and becoming an established member of the system, Jacqueline was relieved that a safety net was in place for her and her husband.

Historical Context

In 1938 President Franklin Delano Roosevelt utilized the first documented gas/brake hand control to accommodate for polio-related lower extremity weakness.^{82,124} OTs, along with driver educators and installers of mobility equipment, have shaped the practice of driving rehabilitation since that time.¹⁴¹ The Association for Driver Rehabilitation Specialists (ADED) was founded in 1977 to provide professional education and support to practitioners in various disciplines involved in driver rehabilitation.^{26,28} Certification in driver rehabilitation for individuals from allied health or other multidisciplinary backgrounds was offered by ADED beginning in 1995. Practitioners with this credential are known as certified driver rehabilitation specialists (CDRSs). As an understanding of driving as both an occupation and an occupational enabler¹⁴¹ grew, the American Occupational Therapy Association (AOTA) implemented a Specialty Certification in Driving and Community Mobility⁹ with the intent of establishing a professional identity and an occupation-based focus for this specialty practice area.¹⁴¹

Expansion of the driver rehabilitation field resulted in mobilization of trade and government agencies to address safety issues. A quality certification program was established by the National Mobility Equipment Dealers Association (NMEDA) for dealers who modify vehicles for persons with disabilities. The National Highway Traffic Safety Administration (NHTSA), a government agency under

the Department of Transportation (DOT) umbrella, also became involved in driver rehabilitation by ensuring that vehicle modifications for persons with disabilities met federal motor vehicle standards. As American demographics changed, NHTSA also provided funding for projects aimed at addressing older driver safety and increasing the capacity of health professionals to meet older driver needs.^{103,105} One of the funded projects was the Older Driver Initiative, launched in 2003 by AOTA.³³

The expectation that more than 71 million senior citizens will be included in the U.S. population by 2030⁴⁹ has brought attention to the issues of fitness to drive, driving cessation, and transportation problems faced by older adults.^{11,45} Collaboration between agencies has been critical for improving the quality and availability of service providers and for developing alternative transportation systems to accommodate nondrivers. The NHTSA has encouraged creation of services by other agencies to extend the period of safe driving and the development of alternative transportation for individuals faced with driving cessation.^{6,102} *The Physician's Guide to Assessing and Counseling Older Drivers*⁷ was developed by the American Medical Association in cooperation with the NHTSA to address the driving safety of older patients and to foster understanding of the public health issues involved. The American Society on Aging (ASA) has also utilized funding from NHTSA to develop educational programs^{19,20} to help professionals better face the challenges of keeping older adults mobile and engaged in their communities.^{35,66}

Other agencies have collaborated to improve driving and transportation alternatives. Project ACTION (an acronym for Accessible Community Transportation in Our Nation) was funded through an agreement with the DOT, the Federal Transit Authority (FTA),⁷¹ and Easter Seals. This program seeks to promote cooperation within the transportation industry to increase mobility for persons with disabilities under the **Americans With Disabilities Act** (ADA) and beyond.^{63,80,145} The American Automobile Association Foundation for Traffic Safety (AAAFTS)¹ sponsors research that uncovers critical traffic safety problems and identifies the most effective solutions to them. A multiagency effort by this agency, the AOTA, the ASA, and the American Association of Retired Persons (AARP) resulted in CarFit, a campaign to help seniors ensure that they have a good fit with their vehicles.^{4,46a,143}

In 1998, AOTA President Karen Jacobs noted that OT had only just begun to identify and reach markets for service.⁸⁷ Since that time, Centennial Vision, provided by AOTA, has been instrumental in shaping the direction of practice in the areas of driving and community mobility. Endorsed by the Board of Directors in 2003, Centennial Vision serves as a roadmap for the future of the profession⁸ and identifies opportunities to expand OT practice to serve individuals, organizations, and communities. Recognition of the societal needs posed by an aging population has

focused attention on **driver training** and rehabilitation, resulting in the designation of this specialty as one of the top six emerging areas of OT practice.^{50,87,139,158} The Centennial Vision strategy of linking education, research, and practice has been implemented by increased scholarly research in the driving and community mobility specialty areas. Evidence-based literature reviews related to OT and driving and community mobility for older adults were published in the *American Journal of Occupational Therapy* in 2008 and 2010.^{51,141}

The benefit of OT in meeting the concerns of older adult clients is demonstrated on an individual basis by programs targeting assessment of driver competency and planning for transition from driving. Additionally, the value of the profession in this area is recognized by other professionals and organizations, including the NHTSA¹⁰² and the American Medical Association (AMA).⁷ Public transit authorities also acknowledge OT expertise in community mobility and often contract with practitioners to perform functional assessments to determine paratransit ridership eligibility.¹⁵⁷ On a national level, the visibility of OT contributions to driving and community mobility has been enhanced through professional contributions to CarFit programs. The Older Driver Website of the AOTA provides resources for practitioners and for consumers, physicians, and others who refer clients to OT services available for older adult drivers.¹⁴

Public Transportation

Community mobility within public transportation includes the use and navigation of transportation systems offered by public and private entities. *Public transportation* refers to services operated by public agencies or supported by public funds.¹⁵⁵ It utilizes buses, trolleys and light rail, subways, commuter trains, street cars, cable cars, van pool services, paratransit services, ferries and water taxis, and monorails and tramways.^{17,18} The two categories of public transportation are **fixed route** and **paratransit** systems. Fixed route systems use defined routes with predetermined stops and run on a published schedule.¹⁵⁵ Trains, city buses, and shuttles are types of fixed route transportation. The paratransit system provides demand-response service within a prescribed geographic area; vehicle dispatch occurs only in response to the request of a qualified rider.⁷³

Jacqueline's OT understood that driving an automobile is the preferred form of transportation for older adults.³⁶ She also knew that inconvenience and fear for personal safety are frequently cited as barriers to the use of fixed and demand-response public transit.¹³⁴ She explored Jacqueline's feelings about using public transportation and pointed out the pros and cons of using this mode of transportation. Armed with information provided to her as a result of the OT intervention, Jacqueline made an informed decision that public transit could meet her needs and qualified

herself and her husband to use their local paratransit system.

Americans With Disabilities Act

The Americans With Disabilities Act of 1990 (ADA)¹ was landmark civil rights legislation for persons with disabilities. Twenty years after it became law, its impact is most apparent in gains in accessibility and transportation. Buses with lifts and sidewalks with curb cuts are common examples of changes accomplished through this Act. In fact, the FTA estimates that by 2006, 98% of bus service was ADA accessible.⁷² Title II of the ADA prohibits discrimination on the basis of disability by all public entities that provide transportation at the local (school district, municipal, city, and county) and state levels. Title III extends coverage to private entities that provide public transportation services.⁸⁰ Most modes of transportation have jurisdiction under the ADA, but transportation that is specifically covered through other laws is excluded. For example, discrimination on the basis of disability in air travel is prohibited by the Air Carrier Access Act of 1986 (ACAA).¹⁴⁹

The ADA regulates buses, trains, ships, and other means of transportation that use fixed and demand-response systems.¹⁴⁷ This legislation establishes accessibility guidelines for buses, trains, and light rail systems, specifying the need for wheelchair lifts and ramps and for securement of mobility aids.² ADA guidelines also provide for priority seating, handrails to facilitate interior circulation, public address systems to announce stops, stop request controls, clearly marked destination and route signs, and various other features intended to ease navigation by persons with disabilities.

Complementary paratransit service is mandated by the ADA, but individuals must meet eligibility requirements to qualify for this demand-response service.¹⁴⁸ Service is available to persons with physical or mental impairments who cannot board and ride accessible fixed route transit systems, whose fixed route system lacks accessible vehicles, or who have specific impairments that prevent getting to and from a stop. Eligible persons who require personal assistance when using paratransit service may have one attendant travel with them at no charge.

Intervention Implications for Fixed Transit

Fixed route transportation using buses or train services creates links among home, school, work, recreation areas, and other important destinations. The FTA estimates that the size of the nation's transit bus fleet grew by more than 25% since 1984, extending fixed transit transportation options to many communities.⁷² Many of these buses are fully accessible. Fixed route systems are more economical and offer greater autonomy and flexibility than demand-response systems; consequently, they present a good transportation alternative for many persons with disabilities and older adults. Another advantage is that fixed route transit is

available to everyone and does not have a qualification process. Consequently, when it is possible to use fixed route services, the role of the OT practitioner is to inform, educate, and encourage the client to do so.¹⁶⁴

Trepidation about traveling alone can make an older adult or a person with a disability reluctant to use the fixed route system.¹⁵⁵ To achieve increased ridership, OTs must match the task demands of the local fixed transit environment with client factors and performance skills.¹⁸ The client's proficiency as a fixed transit user should be evaluated in the actual setting where the individual will be using bus or rail services. It will be necessary to examine whether the client can efficiently get to a bus stop, if bus stops at origin and destination points are safe, whether the individual is safe in boarding and exiting the bus, and if the time at which travel will occur is optimal. Determination of the client's ability to manage the system (handle money, understand transfers, find a seat) and to plan for contingencies such as missing a stop is also important.

If the OT identifies barriers to successful use of fixed transit, a focused intervention plan may be required to remediate or compensate for limited subskills. Strengthening, balance, and endurance programs to enhance ambulation or efficiency in using a mobility device can be carried out in the clinic. Clients can also practice skills such as reading a schedule and managing money in a clinic setting. Additionally, evidence suggests that some mobility device skills practiced in controlled environments can transfer to community settings.¹⁵⁶ However, the natural environment poses limitations that cannot be duplicated or foreseen in the clinic. It is thus very important to practice skills within the context of where they will occur. The environment appears to have a larger impact on processing ability than on individual motor skills¹¹⁶; therefore, performance of bus riding tasks in the clinic may not translate to ability to use the bus.

Similarly, if a recommendation for a scooter wheelchair is to be made, it should first be determined whether the device will actually fit on the platform lift of the bus. Accessibility on an ADA compliant lift is a function of the height of the end flap (ranging from 3 to 8 inches) and the footrest clearance of a given wheelchair. Lower footrests tend to make a wheelchair functionally longer and potentially incompatible with transit lifts. Lifts are located differently and can vary in style from bus to bus. The unique characteristics of each lift will need to be considered in determining boarding techniques. Finally, although a scooter or a wheelchair might actually fit on a lift, its turning radius may exceed the physical environment available on the bus or light rail system.

Some transit systems offer individualized training programs, known as *travel training*, to assist persons who cannot negotiate the fixed route system to travel safely and independently to a regularly visited destination such as work or school. The unique blend of skills and understanding of client and contextual factors demonstrated by OTs make

them perfectly suited to provide travel training to clients who need assistance in using fixed transit. Specialized training in this area is available at no cost through Easter Seals Project ACTION.⁶⁵

Under Centennial Vision, OTs have a role in providing services to communities and organizations. They advise transit agencies about starting travel training programs and confer with city planners and local governments about environmental challenges such as lack of benches and shelters to provide rest areas, less than optimal lighting at a bus stop, inadequately timed crossing lights, and the need to add or modify a curb cut.¹⁵⁷

Intervention Implications for Paratransit

Paratransit offers a viable transportation alternative for many persons with disabilities. OTs can play a critical role in helping clients determine whether paratransit service best meets their community transportation needs. To do this, the practitioner must become familiar with the policies of the local transit company and must clearly understand the client's passenger assistance level. Under the ADA, transit providers have an obligation to provide origin-to-destination services to qualifying individuals.¹⁵¹ The law allows transit companies to determine whether the service provided will be door-to-door or curb-to-curb. In door-to-door service, the driver offers help from the door at the origin point of the trip to the vehicle. Comparable assistance is provided at the destination point. In curb-to-curb, help is not provided until the person actually reaches the curb. Recent guidance from the DOT to transit agencies clarifies that transit agencies with curb-to-curb service must provide assistance to riders who need it because of a disability; however, door-to-door service may be provided only as needed, not necessarily for all rides.⁶¹ The activity demands of curb-to-curb service are much greater than those of door-to-door service. The OT should prepare the client to advocate for door-to-door service if the person's functional limitations require it.

ADA regulations require that the transit system must have a process in place to determine eligibility for complementary paratransit.^{64,151} This process is developed by the transit system in consultation with the local community. Eligibility may be conditional if the person is able to ride fixed transit for some trips but not for others. Examples of situations that might prevent an individual's use of a fixed route service for some trips include weather conditions for a person with temperature sensitivity, presence of a variable medical condition, and environmental barriers at certain locations. An application is usually required to qualify, but some transit systems also ask for supporting documentation, an in-person interview, and/or an in-person assessment of the applicant's ability to use fixed route service. The focus of the in-person assessment used to enforce conditional eligibility is to determine the person's ability to use public transportation, not the extent of their disability.

ADA paratransit ridership increased from 20 million to 45 million annual trips in the 5 years after the ADA was signed into law.⁷⁵ This statistic reflects the demand for this transportation service. Unfortunately, the costs of providing a paratransit trip are significantly higher than for a fixed transit trip—often 10 times more expensive.⁷⁵ The high expense of providing paratransit service has caused some transit providers to implement a stringent eligibility certification process as a way to contain costs.⁷⁵ OTs have a potential role in all aspects of eligibility certification.¹⁵⁷ To ensure appropriate categorization of a disability, assistance can be provided during the application process. Clients can be encouraged to accurately report all significant disabling conditions that interfere with using fixed route service. Assistance during the interview process could involve educating the person to provide necessary documentation of these problems and helping him or her to articulate the difficulties encountered when using fixed route service, for example, by describing an inability to wait at a bus stop. OT services are also needed by transit authorities to determine whether a person's wheelchair conforms to the common wheelchair ADA requirements, to prescreen an applicant for balance and motor capabilities, and to conduct an assessment of the person's skills during an actual transit trip.⁸¹

OT interventions may include orientation to the local system, training in making a reservation, and education related to service limitations. Paratransit ridership combines trips of several individuals to meet the capacity of the vehicles; consequently, travel often takes longer than **private transportation**. It can, in some cases, exceed fixed route timelines. Long trips can pose hardship to those whose medical conditions or symptoms include urinary urgency and frequency, pain with prolonged immobility, insensate skin, or decreased endurance. OT intervention in such cases may call for cushioning and positioning devices to decrease discomfort and fatigue during the trip. Clients who are reluctant to travel alone gain confidence in their abilities when accompanied on a trip to a destination and back.

Clients may also benefit from instruction on planning a trip and discussing contingency and safety preparations. Food, water, and shelter may not be available at drop-off points. On some occasions, miscommunications or errors cause a delay in or outright cancellation of a ride. As with fixed transit, the unaccompanied rider needs a certain degree of resourcefulness and problem-solving skill to navigate the system safely and efficiently. Jacqueline became a paratransit rider to provide herself with transportation and to accompany her husband to appointments. She was concerned about the long ride because her doctor's office was an hour from her home. With travel time, waiting, and the doctor visit factored in, they could potentially be away from home for 3 to 5 hours. Her therapist recommended that she pack appropriate diabetic snacks to properly maintain her husband's blood sugar level and avoid low blood sugar problems during their journey.

Private Transportation

Private transportation relies on consumer vehicles that are privately owned, either individually or by an entity collectively. The primary advantage of private transportation is the on-demand, 24-hour availability of origin-to-destination travel, the flexibility to modify travel plans, and the strong sense of control over one's life. Individuals in rural areas that are not served by fixed transit routes may have no alternative but to utilize private transportation. The primary disadvantage of private transportation is cost: the individual is responsible for access needs, for fuel, and for keeping the vehicle and any driving modifications mechanically sound. Nondrivers who own vehicles face additional costs of hiring drivers; this limits on-demand transportation.

Persons who prefer the convenience of private transportation must plan for replacement costs of the vehicle to retain independence. Future expenditures can also be expected for compensatory adaptations necessitated by aging and long-term disability.^{34,94} An emerging trend may result in additional costs, as mobility equipment dealers begin to require a driver assessment before adapting a vehicle. Costs and vehicle responsibilities prohibit many from private transportation options.

Supplemental Transportation Programs for Seniors

The aging of America has resulted in a focused effort to develop supplemental transportation programs for seniors, also known as STPs.³⁶ Their primary purpose is to support the gap in transportation services for older adults, particularly those over age 85, who most likely do not drive. They may also serve people with disabilities, however. Key to these programs is that they offer assistance that is unavailable through public transit and ADA paratransit. STPs may be sponsored through senior centers, hospitals, city councils, paratransit, places of worship, or a city office on aging and door-to-door, door-through-door assistance at the destination and escort service may be provided. Services are available at a variety of times, often permit multiple stops, and may allow jurisdictional boundaries to be crossed. Volunteer drivers, paid drivers, or a combination of both may be used. Some STPs have their own vehicles purchased through public funding. Others, such as volunteer driver programs, rely on the vehicles of their volunteer drivers. The Beverly Foundation, a technical assistance program that encourages senior mobility and transportation,^{34,35} has defined the factors necessary for senior-friendly transportation: availability, accessibility, acceptability, affordability, and adaptability. By being involved in senior mobility issues in the community, OT practitioners can learn about appropriate transportation alternatives to driving and can help disseminate information about these alternatives, adding their unique expertise to the process.

Intervention Implications

Some clients who are considering driving will request OT consultations to explore the process involved and to identify costs for private transportation based on their diagnosis and function. In one such case, a client with a C5 spinal cord injury discovered that the level of technology he was likely to need to be able to drive was expensive. If he proved to be a successful driver candidate, the vehicle and adaptations alone would cost more than \$100,000. This figure does not reflect the cost of the comprehensive evaluation or the extensive driver's training. The client appreciated learning the assistive technology required for his injury because it provided pivotal information for his transportation planning. Some people value driving so highly that they would gladly pay such costs out of settlement or other funds. However, this client decided not to drive, stating, "That sure would buy a lot of taxi rides!" By providing a "mini" evaluation or consultation, the client was given the critical information he required to plan his future optimally. He learned that he probably had the ability to drive but made an educated decision to use his resources for a different transportation plan.

Driving is but one aspect of private transportation within the practice area of community mobility. Passenger evaluations, which can significantly improve the safety of the caregiver and the rider, are too often overlooked as a focus of intervention. If the person to be transported uses a wheelchair and cannot transfer to a vehicle seat, the OT can be an important source of information about how the wheelchair can be safely transported. In a school setting, OTs are responsible for students who use wheelchairs, including their safe transport to and from school.¹³⁶

The basic elements for protecting passengers seated in wheelchairs within motor vehicles are (1) a safe vehicle, (2) a forward facing vehicle, (3) a crash worthy wheelchair, (4) effective wheelchair securement, and (5) effective occupant restraint.⁷⁷ The voluntary ANSI/RESNA WC19 compliance standard describes the type of wheelchair that can be used as a seat in a motor vehicle. Such a wheelchair has a frame and transit components that have been crash tested, four securement points, specific securement point geometry, a clear path of travel for proper placement of vehicle-mounted occupant safety belts, and anchor points for an optional wheelchair-anchored pelvic safety belt.¹²⁷ OTs can help clients advocate for a WC19 wheelchair by providing justification and documentation of need.⁷⁷ School-based therapists can collaborate with other therapists in ordering a wheelchair to make sure that it can be safely used to transport a child.¹³⁶ Practitioners will find a list of wheelchairs that comply with the WC19 standard available on The Rehabilitation and Engineering Research Center on Wheelchair Transportation Safety (RERCWTS).¹²⁸

A complete wheelchair tie-down and occupant restraint system (WTORS) must be used to safely transport a person in a wheelchair. A WTORS attaches the wheelchair to the vehicle with a four-point strap-type tie-down. Wheelchairs

can also be secured with an SAE J2249 or ISO 10542 compliant docking tie-down device.⁷⁷ Adaptor hardware attached to the wheelchair frame engages with the docking tie-down device installed in the vehicle.¹²⁹ To protect the rider, a seat belt system with pelvic and upper torso belts must be used.¹²⁹ OTs should recommend that WTORS be installed by vehicle manufacturers or accredited members of NMEDA. The WTORS must be manufactured by a single supplier, labeled as meeting crash standards, and installed according to manufacturer's specifications.⁷⁷ Knowledge of these standards will ensure that safety is not compromised.

A skilled therapist can identify and recommend the secondary postural supports (head supports, lateral pads, butterfly vests, and pommels) needed to help a passenger sit with good posture.¹³⁶ OTs should keep in mind the caregiver's physical capacities in making recommendations for equipment. Because the tight confines of a bus, car, or van pose challenges to ease of movement, educating and training caregivers in body mechanics and joint protection is essential for safety and injury prevention.^{32,136}

OTs can be instrumental in educating attendants and transporters in safe loading of a wheelchair onto a lift (passenger facing away from the vehicle and wheel locks applied) and in deciding whether an individual with a power wheelchair can safely drive onto the lift.¹³⁶ School-based therapists have opportunities to work with transporters in developing a bus evacuation plan for disabled students.¹³⁶

Specialized Needs

When life support devices are required in a vehicle, safety dictates provision of a backup energy source in the vehicle through a device known as an *inverter*. An inverter converts a 12-volt DC battery source to common 110-volt AC power and provides an instantaneous plug-in source of power if the life support device battery fails.

Safe transport of infants and children with medical needs or disabilities is another area of practice that should not be overlooked. Car seats should not be modified unless the person performing the modification is certified to do so. Inappropriate car seat adaptations recommended or made with good intentions can have life-threatening implications.³⁵

Assessment for children and teenagers must take into account future physical growth. For example, a 6-year-old riding in a van seated in a wheelchair may no longer fit in the vehicle by age 15 because of increased height. Also, activity demands associated with caregiving will be greater for a 15-year-old than for a 6-year-old. Alternative mechanical or power lifts or adaptations may become necessary for children or adults when their body size becomes unmanageable (and therefore unsafe) for their caregiver. Both growth and development and aging impact the equipment that will meet needs at a given age. Jacqueline, the client described in the case, may need to consider specialized passenger seats designed for the elderly. These motorized seats move outside

FIGURE 11-18 Bruno's Lift-Up power mobility seat for Toyota Sienna minivans aids vehicle entry by modifying activity demands for caregiver and client.

(Courtesy Bruno Independent Living Aids.)

the car and rotate, easing the activity demand of car transfers through compensatory mechanical movement and power (Figure 11-18).

Driving

Driving is cited again and again as the basis for personal independence, employment, and aging in place.^{7,59,102} A driver's license has deep social and cultural contexts; it serves as a rite of passage for the teenager, provides the adult with an ability to pursue employment and recreational opportunities, and gives the aging population competence and wellness. Driving competence is regarded as instrumental for obtaining and maintaining an independent lifestyle and for aging in place for the older adult (Figure 11-19).

Occupational Therapists and Driving

An understanding of the implications of medical conditions and disease processes, the ability to analyze ADLs and IADLs, knowledge of adaptive devices, and occupation-based interventions make OT practitioners uniquely qualified to provide driver rehabilitation. The social impact of an aging population (20% of the U.S. population will be 65 or older in 2030)⁷⁰ has brought the issues of maintaining independence and quality of life, especially as they pertain to driving, to the forefront of attention. OTs already make up the overwhelming majority of professionals providing driver rehabilitation services for the physically disabled population.⁹² The profession has responded proactively to an increased number of senior drivers through the AOTA Older Driver Initiative.⁹⁰ However, given the increasing numbers of senior citizens who grew up relying on cars to engage in occupations, the need to train additional therapists in this specialty practice area is tremendous.⁵

FIGURE 11-19 This client was experiencing difficulties driving and at work, as progression of her multiple sclerosis exceeded the activity demands of pushing a manual wheelchair. Driving from a power wheelchair and using an electronic gas-brake hand control decreased the activity demands on her upper extremities, enabling her to drive safely and work full-time as a teacher.

Ethical Considerations

Driver rehabilitation specialists have a responsibility to their clients and to the larger community as well. Public safety is an important concern.

Generalist and Specialist Roles

All OTs should explore how impairments impact driving and should set goals related to their clients' driving and community mobility needs.¹¹⁷ Generalists should sufficiently understand the skills needed to play a role in initial decisions about driving, but should appreciate that the clinical screenings they administer can neither confirm driving capability nor rule it out as a goal.⁹⁰ An OT driving specialist (DRS) should be contacted if any questions about driving safety arise (Box 11-2). Driving presents a greater possibility of personal and public harm than does any other ADL or IADL; therefore OTs offering driver evaluation services receive advance training to effectively intervene in this complex occupation.¹⁵ OT driving specialists administer assessments specific to the requirements of driving, including those for vision, cognition, motor performance, reaction time, knowledge of traffic rules, and behind-the-wheel assessments of skill.¹⁵ They recommend whether to continue, modify, or cease driving; suggest vehicle modifications and adaptive devices; provide driver retraining or specialized driver education; and document all findings. OT practitioners who specialize in driving must be certified driver instructors to perform on-road assessments and provide driver training in some states.^{15,122}

Ethical Considerations

No therapist should proceed with on-road driver evaluation without first meeting the industry standard or equivalent for driver instructors within his or her own state. Proceeding without this basic driver instructor training is not recommended; it has the potential to be unsafe and to result in the therapist teaching techniques incorrectly that must later be unlearned.

Specialty Training and Certification

Professional specialty designation expedites services, ensures appropriate matches between practitioner skills and client need, and validates the depth and breadth of OT practice.^{1a,10} The AOTA has recognized that Board and Specialty Certifications communicate expertise to consumers and professionals outside of the profession, and that they are recognized as quality markers by accrediting and regulatory agencies and sources of reimbursement.⁷⁸ The AOTA offers a Specialty Certification in driving and community mobility for OT practitioners (OTs and certified occupational therapist assistants [COTAs]). This specialty designation is based on a peer-reviewed reflective portfolio. The process is prospective and includes three major sections: background, reflective portfolio, and ongoing professional development.⁹

The ADED offers certification in driver rehabilitation (Box 11-3). The CDRS credential allows individuals from allied health and driver training backgrounds who meet the

criteria for educational background and experience to sit for an examination covering driver education, disabilities, and vehicle modifications.²⁶ In some states, agencies such as the Department of Rehabilitation require the CDRS credential to provide services.

OTs with a specialty in driving may benefit from professional development by attending traffic safety and driver education courses. Driver instructor courses provide training in identifying behaviors and habits, teaching proper driving techniques, minimizing collision risk during an

evaluation, recognizing specific driving pattern characteristics of novice and older drivers, and implementing training exercises and programs to improve outcomes. Resources for training include the local department of motor vehicles office, state trooper organization, high school driver education program, traffic safety council office, AARP, or driver refresher course, and ADED conference presentations.¹²¹

Ethical Considerations

Principle C-46 of the Association for Driver Rehabilitation Specialists' (ADED) Code of Ethics: "Driver rehabilitation specialists use only assessment techniques that they are qualified and competent to use. They do not misuse assessment results or interpretations."

Occupational Therapy Assistants

The OT assistant (OTA) is a valuable asset to driver rehabilitation. Completion of standardized testing, vehicle entry/exit and lift safety training, transfer training, and functioning in the role of driver instructor are just some of the ways the OTA can contribute to a driving program. The OTA must work under the supervision of, and in partnership with, the OT.¹²

Appropriate utilization of OTA skills can be an asset to driving programs by assisting with cost containment. Expanded roles are possible when intervention protocols are developed, documented, and followed, again under the supervision of the OT. For example, OTAs can be utilized to determine the need for progression in driver training, if the driving skills being observed have been defined and training in recognizing them has been provided to the OTA. Clear treatment protocols facilitate supervision by enhancing communication between colleagues.

Driving Program Structure

Therapists can be based in an agency, private practice, or hospital, and can offer different levels of services, ranging from referrals, consultations, and clinical screenings to comprehensive driver competency assessments. Most programs have just one driving program staff member in the vehicle during an **on-road evaluation**—usually the therapist fulfilling the evaluator and driving instructor roles. Additional specialization and expertise are required of the therapist when higher levels of driving technology are introduced.

Some programs choose to use staff or contracted driver instructors for the on-road portion while the therapist makes observations from the back seat. A variation is for the instructor to conduct the on-road evaluation alone without the therapist and report to the therapist on performance level. This is not recommended, especially when the client has significant mobility or performance skill

involvement, because the therapist's unique training may identify an issue otherwise overlooked. Programs with just one professional in the vehicle should consider outlining special criteria that would mandate the need for two staff members during the on-road assessment. Two professionals in the vehicle can offer better security and protection, for example, when witnesses are desired for all direct client contact.

Models of Practice

Practice models provide guidance for established and new driving programs and identify conceptual areas and detail practices that should be considered. In 2002, NMEDA and ADED released Model Practices for Driver Rehabilitation for Individuals with Disabilities, focusing on agency-sponsored evaluations and vehicle modifications, such as the Department of Rehabilitation (DR).¹⁰⁸ In 2004, the ADED published Best Practices, delineating frameworks for driver rehabilitation services.^{24,25} In some states, the DR has existing guidelines and role delineations, which provide further models and references.^{137,138}

Driving Program Goals

Driving competence can be disrupted by a single disability, multiple medical conditions, or factors of aging.³² Driving programs seek to provide safe and independent transportation for individuals. One may participate in transportation as a passenger or as a driver. Driver program services provide assessment in a natural environment under real-time conditions—an important aspect because outcomes in general can be overestimated in clinical settings.²³ The performance skills and activity demands of the client, as well as other client factors, are assessed in efforts to determine what restorative, compensatory, or preventive interventions may be needed for safe transportation or driving.

Goals must include the specific driving occupations in which an individual wishes to engage. Although independent driving is the general goal, subset occupations exist within the task of driving. Some drivers want only to drive to the store, doctor, and church; others want to return to a job in which driving is an essential function of employment. A divorced or single mother with severe chronic pain may wish to regain the ability to transport her child for parental visitations. Driving needs and associated activity demands are personal and specific; identification of each client's occupational needs is paramount to a meaningful assessment and a successful outcome. When needs and demands are identified early, the occupation of driving and required subskills can be interwoven into the fabric of intervention.

Best Practices Identified

Driver evaluation is a process that is dynamic and fluid (Figure 11-20). An individual's readiness, performance skills, and rate of learning can affect the ease and speed of completing the driver evaluation process.¹⁴⁴ Recommended

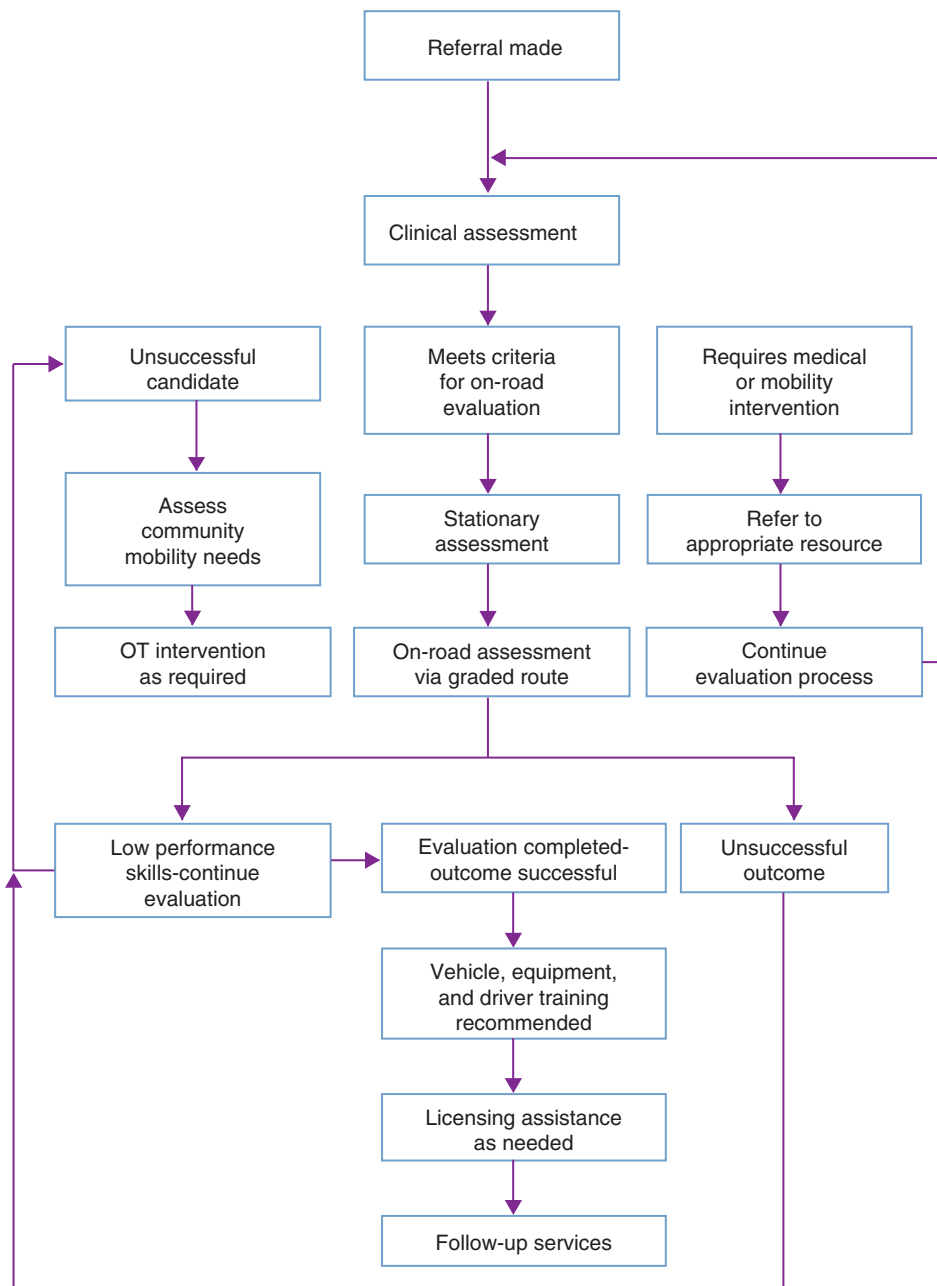

FIGURE 11-20 The flow chart illustrates the complexities and dynamics of the driving evaluation process.

and Best Practices provide frameworks that accommodate any level of a client's performance skills.

Best Practices from the ADED include a clinical evaluation followed by (1) an on-the-road evaluation in an actual driving environment, (2) subsequent vehicle modification recommendations and wheelchair measurements, (3) recommended driver training and education, (4) a final fitting, and (5) licensing assistance.^{25,81} An on-road evaluation is indicated when program criteria are met. Programs set varied criteria based on specialized training received by staff, the scope of the program, comfort level, and safety issues. Recommendations for adaptive equipment are not advisable until a driver demonstrates in a behind-the-wheel

assessment competency to access or use the equipment or a similar device.

Program Criteria

Driving programs must establish the necessary elements of an evaluation process and objective performance criteria to enable consistent and accurate decision making against which progress (or lack of it) can be measured. Use of Best Practices also provides a measure of liability protection. *The Physician's Guide to Assessing and Counseling Older Drivers* (prepared by the AMA) outlines different levels of assessment, from the interview to a formal driver assessment.⁷ Factors listed as prompting physician concern about a

client's driving skills include acute events, chronic medical conditions, questioning of safety by an individual or family members, conditions that are unpredictable or episodic, and use of specific medications. These factors may also serve as a basis for development of criteria for driving assessments and behavior evaluations.

Ethical Considerations

Therapists in this practice area must be able to withstand significant pressure in their decision making. A novice driver with significant cognitive and perceptual impairments, for example, may press to curtail the assessment process prematurely because of time and financial considerations. Pressure to sway the therapist's opinion before completion of an assessment may come from biased third party payers; even family members may strongly attempt to influence the outcomes of the assessment in a direction that is not supported by performance observations.

Referral Process

Physicians, allied health care professionals, family members, and individuals are appropriate referral sources for community mobility and driving assessments. The referral process may be simple or complex and cannot always be completed in a seamless fashion. Verification of an individual's insurance coverage can be time-consuming. Most private insurance sources do not pay for evaluations, and government insurance, such as Medicaid and Medicare, generally follows the private insurance industry. Although some therapists are able to obtain Medicare coverage, the reimbursement rate rarely covers the full costs of the assessment process.⁵

Each program must set criteria for accepting a referral for driver evaluation. A physician's referral, recent medical records, a confirmed payment source, and a valid driver license or permit (for on-road segment) are frequently required. Most programs also create an intake form on which to record relevant background information about the client. During the referral process, it is important to communicate the program's intent, so that anxiety can be minimized. Jacqueline was worried until the therapist from the driving program called and spoke with her. She was relieved to hear that an array of options was available to meet her needs. She had considered canceling the evaluation because of the devastating impact that loss of her license would have, but chose not to after reviewing goals with her therapist. As a result, she arrived for her evaluation optimistic and ready for productive changes in her driving system.

Driving Evaluations and Disabilities

Many different types of disabilities influence driving ability. Therapists can apply their knowledge of various conditions to understand the client factors that might be affected, and

to anticipate how disease progression could influence the need for driving equipment over the course of time. The ADED Website provides fact sheets that discuss driving issues and assessments for several different types of disabilities.²⁷ A discussion of driving issues related to some commonly seen disabilities is presented in the following sections.

Spinal Cord Injuries

Spinal cord injury (SCI) is the second leading cause of paralysis in the United States.⁴⁹ The National Spinal Cord Injury Statistical Center at the University of Alabama at Birmingham reports that 262,000 people in this country have sustained an SCI.¹⁰⁹ A significant percentage of SCIs are incomplete, and individuals may have motor and/or sensory function below the level of the lesion.¹¹⁰ Individuals with such injuries can be challenging in driver rehabilitation. Intervention requires the OT to engage in critical thinking, collaborate with physical therapy, and determine whether the client can demonstrate the necessary performance skills to meet the activity demands of driving without undue fatigue. Adaptations for driving may be temporarily needed while prolonged recovery occurs. Clients who have sustained complete SCI injuries have more straightforward intervention protocols based on the level of injury. All individuals who have sustained spinal cord injuries, however, have a high frequency of multiple diagnoses, including mild or undiagnosed traumatic brain injury (TBI).⁹⁷ Therapists need to remain alert to possible signs of TBI so that intervention services can be modified accordingly.^{46,111}

A driving evaluation for the client with an SCI focuses on the occupational performance subskills basic to all evaluations. Performance areas include mobility of a wheelchair or other wheeled device to and from the selected vehicle, transfers between the wheelchair and the vehicle, and overall vehicle entry and exit. The ability to manage equipment, including loading and unloading wheelchairs and locking and unlocking long leg braces, is also important. A thorough evaluation should assess driving competence in a natural setting and should ascertain the ability of the client to meet activity demands. The need for compensatory adaptive equipment must be established. Upper torso supports or chest straps are frequently recommended to maintain an upright position during a sharp or fast turn³⁷; a diagonal seat belt alone may not be adequate to inhibit lateral movements.

Steering devices may be needed to accommodate hand and upper extremity impairments, and pedal blockers may be necessary to prevent accidental activation of the brake and gas pedals by lower extremity spasms.

In clinical practice, most individuals with paraplegia and tetraplegia at the C7-8 level can drive a car that has the following modifications (Figure 11-21):

1. Standard power steering and power brakes with automatic transmission.

FIGURE 11-21 A basic setup for paraplegics includes spinner knob for steering and mechanical hand controls to operate accelerator and brake. This equipment can be used in many cars, vans, trucks, and sport utility vehicles.

2. Mechanical hand controls to operate accelerator and brake.
3. A steering device, usually a spinner knob or V-grip.
4. An upper torso support strap (this is a positioning device only and should never be considered as a safety device to replace a seat belt).
5. Accessible or remote switch for horn, dimmer, wipers, and turn signals.
6. A parking brake extension.

The Consortium for Spinal Cord Medicine Clinical Practice Guidelines suggest that independent driving from a wheelchair is possible for persons with C6 tetraplegia; however, achieving this functional outcome depends on the unique characteristics of the case.⁵⁷ An extensively modified van may be required when an individual is unable to transfer independently, or when transfers are physically taxing.³⁷ Structural modifications to the van (e.g., a raised door, a raised roof, a lowered floor) may be necessary to accommodate the wheelchair and the driver. With current technologies, and after extensive evaluation and training, some clients with a C4-5 SCI can safely drive systems with high-technology modifications (Figure 11-22).

Driving From a Wheelchair

When a person needs to drive from a wheelchair, client education and informed choice are necessary to address increased safety risk. It is generally accepted that the hierarchy of safe seating for a driver begins with the driver seat

FIGURE 11-22 High-tech equipment compensates for limited motor skills. The evaluation van equipped with electronic mobility controls (EMC) has a left-side electronic gas-brake, a remote left elbow secondary control button, a 7-inch remote steering wheel (*on right*) with trip-in steering device, and a membrane switch console for functions including gear shift, windows, and headlights.

of the original equipment manufacturer (OEM), which is designed to withstand crash forces. The OEM seat is followed by an aftermarket powered seat base (which moves up/down and forward/back and rotates to facilitate transfers). Driving from a wheelchair is next, with a power wheelchair considered safer than a manual wheelchair, even when both are WC19 compliant. Both types of wheelchairs have been crash tested at low speeds, but the heavier weight of the power wheelchair allows it to withstand forces at the higher speeds typical in many driving situations. For safety reasons, it is not possible to drive from a scooter.

Driving from a manual wheelchair can present several complicating factors. Some persons lack the strength to push the manual wheelchair up the ramp of a lowered floor minivan, which has a 1:6 slope. This slope is twice as steep as the minimum slope for an ADA ramp and consequently requires more strength to navigate. Compounding the problem is the fact that the weight of the device required to secure the wheelchair to the van floor adds 10 to 15 pounds to the wheelchair. Still another problem is that the securement device, which is permanent, precludes a folding wheelchair from folding.

When the client is driving from a wheelchair, a wheelchair assessment is needed to ensure that the person is stable and appropriately positioned, and that the wheelchair is compatible with driving.³⁷ A wheelchair that is too wide can make it difficult to position an individual squarely in front of the steering wheel for optimal control. Some wheelchairs in which the seat rests on a single post are not suitable as a driving platform, because the post is prone to shear on impact. Other wheelchair models have independent suspension and can negatively impact driver stability by causing inadvertent movements. Driver stability is critical to safely operate certain high-tech control systems, because inadvertent movements can result in loss of vehicle control. Last,

OTs must be aware of whether the type of wheelchair being considered for their client has automatic lock-down systems. Powered lock-down devices are not available for all models of power wheelchairs.

Traumatic Brain Injury

Approximately 1.7 million people in the United States sustain a traumatic brain injury (TBI) each year.⁴⁶ TBI can impact driving by disrupting the motor control and attention needed to maintain constant lane position, thereby diminishing the accuracy of visual perception and memory and decreasing visual problem solving, eye-hand coordination, and reaction time.⁴¹ It is no surprise that the severity of TBI is related to the individual's ability to drive safely; however, research shows that between 40% and 60% of people with moderate to severe brain injury return to driving after injury.¹⁴⁶ A large number of these people do not undergo evaluations for driving competency.⁵²

Self-report and the perceptions of close relatives about an individual's fitness to drive have been shown to be strong predictors of whether a person with TBI would return to driving,¹²⁶ suggesting that OTs should begin the evaluation process by gathering information from the client and family.⁵² OTs should be careful about the timing of consultations, pre-driving assessments, and referrals to on-road driving programs with clients in this group. Clients whose functional return has stabilized require less adaptive equipment than those who are newly injured. A referral made too early can use up limited therapy visits from an insurance provider or can tax the financial resources of the individual or family. Exploration of driving potential becomes appropriate when evidence indicates that the client has insight about his or her physical and cognitive limitations, and when improvement in factors such as the ability to demonstrate new learning, divide attention, and incorporate good judgment into decision making has been demonstrated.

Consultation with the driving specialist can help the therapist identify performance skill needs that can be integrated into inpatient, outpatient, day treatment, or community intervention programs before the actual referral is made. Evidence suggests that the Useful Field of View (UFOV),³¹ a test that measures aspects of visual attention, is predictive of the attention and visual processing skills needed for on-the-road performance in individuals with moderate and severe TBI.⁵² Consequently, areas of focus during pre-driving training might include enhanced rapid understanding of visual information¹⁴⁶ or an improved attentional window, so that more visual information is taken into account when driving decisions are made (Figure 11-23).^{32,114}

Active Passenger and Narrative Driving

This therapy program is performed in a moving vehicle. The client can participate only as a passenger for safety reasons. Tasks of visual scanning and coordination are performed with the client ideally in the front passenger seat of

FIGURE 11-23 The attentional window or white area appears normal in the first slide and continues to shrink as visual processing speed and divided attention are increasingly impaired.

the vehicle. However, these tasks have also been successfully assigned to people secured in their wheelchair in the back of a paratransit vehicle. The activity is designed to establish new behaviors and habits for novice drivers, and to improve, speed up, or reinforce patterns and behaviors in experienced drivers. The goal of the “active passenger” is to visually scan and then verbally narrate salient contextual changes in the environment, such as road signs, road markings, traffic signals, hazards, or developing situations that require attention. This should be done only for a brief period—10 to 15 minutes—until endurance is built up. For example, a client with a head injury may travel with a parent, and as they travel down the road may call out, “Pedestrian on the right, red light, 35 mph sign, car turning left,” etc. Several variations of the activity may be tried:

- The driver and the “active passenger” can play together to see who sees the situation or directional signs first.
- The “active passenger” can perform all motions of driving—head turning, steering, gas/brake, turn signal indicators—in addition to narrating the route.
- The “active passenger” can act as a navigator with written directions to a destination. The driver should know the route ahead of time.

Therapists who use this program need to carefully match home program demands with the performance skill of the client and other client factors. All variations of the program should start in low-speed residential areas and should increase to faster speed zones as visual scanning improves.

Progressive Mobility

Progressive mobility programs are an excellent way to provide clients with a graded experience with opportunities for improvement. Used as a precursor to driving, or as a home program, progressive mobility programs are valuable in identifying progress and appropriateness for a driving referral. The person must be competent in simple, low-speed contexts before mastering more complex ones.

The concept is to increase the speed at which an individual is moving to give the body opportunities to integrate appropriate responses with the contextual features of the environment. Collaboration or co-treatment with physical therapy is necessary to verify an individual's ability to perform the separate motor task before additional therapeutic demands are introduced. The hierarchy of a progressive mobility plan may appear as follows:

- Low-speed ambulation or wheeled mobility graded from light to crowded indoor environments (hospital, shopping mall) with successful outcome indicated by appropriate directional changes, recognition and use of communication, and safe motor skills in a smooth, integrated pattern
- Moderate- to fast-speed ambulation or wheeled mobility indoors and in natural community contexts with the same parameters as above and with greater emphasis on dynamic and flexible responses to real-time changes in a situation
- Graded bicycling or wheeled mobility in light to congested outdoor areas (quiet park or residential street, surface streets) with emphasis on integration of visual/perceptual systems with performance skills and patterns

Cerebral Vascular Accident

A cerebral vascular accident (CVA) can have varying results on function depending on the anatomic brain structures that are damaged. Deficits that can interfere with driving include hemiparesis or hemiplegia, visual limitations, problems with memory and concentration, slowed reactions, spasms, speech and reading difficulties, and other consequences.¹⁴² One study of driving after stroke estimated that

in a sample of 239 stroke survivors, 30% of those who had driven before the stroke returned to driving after the stroke.⁷⁴ Almost half of this sample did not receive any professional advice about driving, suggesting a potential area of intervention for OTs.

Hemianopia is a common occurrence following a CVA.¹²³ Visual field loss is of concern to the OT because it can significantly impact driving safety.⁷ However, evidence suggests that people with hemianopia or quadrantanopia with no lateral spatial neglect can demonstrate safe driving.⁶⁹ Whether or not hemianopia interferes with safe driving may vary from individual to individual and may depend on other factors, including the absence of visual neglect and other visual spatial disorders.¹⁶³ To best advise clients, OTs will need to familiarize themselves with the department of motor vehicles (DMV) visual field requirements in their states, because they vary substantially.¹¹⁸

Equipment used for driving after a CVA depends on the individual's functional impairments. If the person cannot steer with both hands, a steering aid may be needed to assist with turning. When paralysis of the right leg occurs, modification of the vehicle with a left foot accelerator might be appropriate, if the person is able to operate it reliably. Extra mirrors may be necessary to compensate for visual deficits.

Older Drivers: A Growing Population

Driving a car is the preferred transportation for seniors¹³⁰; however, aging and age-related diseases can lead to unsafe driving, vehicle crashes, or driving cessation.⁸³ Because of increased susceptibility to injury, fatal crash rates for older adults start to rise at age 75 and increase significantly after age 80.⁸⁴ This statistic and figures showing a growing population of older drivers (20% of the population by the year 2020),¹⁵⁰ as well as an increase in crash rates per mile driven by age 70,⁸⁵ have made senior driving an urgent public concern. Age by itself, however, is not sufficient for assessment of driving ability. The impact of functional impairments appears to play a role in safe driving and can become evident in stressful situations such as merging or changing lanes.⁸⁵

Traditionally, OTs have recommended adaptive equipment for senior drivers. However, several new directions for practice have emerged from systematic literature reviews of older adult driving research.⁵⁵ For instance, therapists are encouraged to help clients understand the role of medical and pharmaceutical treatments for visual, cognitive, and motor problems and to educate them as to their impact on driving.⁸³ Other evidence implies that interventions should employ experiential training with sensory and cognitive elements to remediate impaired skills in vision, cognition, and motor function. To help clients develop compensatory strategies to restrict driving (e.g., driving only during the day, omitting travel during peak hours), research suggests that intervention should be designed to foster self-awareness about driving limitations. Finally, to increase client

Threaded Case Study Jacqueline, Part 2

Jacqueline has impaired neck and hand range of motion (ROM) as a result of arthritic changes. Jacqueline was issued an adaptive key holder to open the car door and a recommendation to purchase a steering wheel wrap to build up the grip on the steering wheel; the knobby wrap provided a larger-diameter wheel to grip. When neck rotation for blind spot checks was discussed, she reported that she has had “near misses” while changing lanes, nearly colliding with cars she didn’t see. It is important to note that many older drivers never received formal driver training and are unaware that a blind spot check is required. In Jacqueline’s case, it is a skill that requires mobility that she doesn’t have, such as turning the head enough to look behind her shoulder.

Introduction of a wide-angle interior rearview mirror and blind spot mirrors on her exterior mirrors greatly improved Jacqueline’s safety and confidence in seeing what she needed to see. She was also assisted in properly adjusting her driver seat to the appropriate position behind the wheel; in her current car, the old seats caused her to sit too low. Sitting lower than was optimal resulted in poor field-of-view out the windshield, in addition to a poor mechanical advantage in turning the steering wheel. An additional cushion was required to raise her so that her eye level was 2 to 3 inches above the top of the steering wheel.

Her performance on the road was greatly improved by these changes. Jacqueline’s driving was now at a safer and more competent level. However, when an older adult has limited driving competence even with adaptations or interventions, the therapist should consider graded licensing, which permits driving under certain limitations (e.g., dawn to dusk, no freeway). A recommendation for a graded license extends the older adult’s ability to function independently.^{4,27}

commitment, practitioners are called on to clearly relate interventions to driving skills. Additional research suggests that OTs must gain awareness of how driving errors relate to traffic violations,⁵³ must play a role in formulating public policy related to older driver relicensure,¹⁴⁰ and must advocate for roadway construction³⁸ and vehicle design²² that support senior driving.

Resources to Help Seniors

Self-report measures are based on self-assessment and can help the therapist to identify driving behaviors, increase driving safety awareness and knowledge, and promote safer driving outcomes among older adults.⁵⁴ These measures can be helpful for initiating discussions about driving safety and for encouraging at-risk drivers to seek further assessment.¹¹²

- The *Driving Decisions Workbook*,¹⁵¹ developed by the University of Michigan Transportation Research Institute, is a paper-and-pencil self-assessment tool for older drivers who are experiencing declines in their driving abilities. It provides information about

health-related changes in abilities and feedback as to how these changes influence driving, and it suggests strategies for increasing safety. The Self-Awareness and Feedback for Responsible Driving (SAFER Driving) survey is a Web-based survey that asks questions about how health concerns caused by medical conditions and medications impact safe driving. The survey calculates how these health concerns cause driving declines, provides individualized feedback for continuing safe driving, and advises professional assessment if needed.¹⁵²

- The Seniordrivers.org Website portal offers several different self-assessments of driving skills.¹³¹ The Roadwise Review is a free online screening tool that measures eight functional abilities (leg strength and general mobility, head/neck flexibility, high- and low-contrast visual acuities, working memory, visualization of missing information, visual search, visual information, and processing speed) that are best correlated with safe driving. The Drive Sharp Calculator is a 5-minute screening that rates crash risk based on the useful field of view. The Drivers 55 Plus is a 15-question self-rating form that includes questions, facts, and suggestions for safe driving.

The American Society on Aging (ASA), in cooperation with NHTSA, has developed two educational programs to help professionals better address the challenges of keeping older adults mobile. The DriveWell ToolKit and Training Program¹⁹ seeks to promote community conversations and improved driver safety and transportation choices, to influence older drivers to change when and how they drive, to encourage the use of alternate forms of transportation, and to stimulate communities to offer transportation choices to meet the needs of older adults. The Driving Transitions Education Program²⁰ provides professionals with step-by-step procedures for responding to inquiries about driver safety, preparing seniors to make decisions related to mobility, and increasing professional competency and comfort when addressing transportation alternatives.

CarFit, a joint effort by AOTA, ASA, AARP, and AAA, is a national campaign designed to help seniors ensure that their vehicles are properly adjusted to them.^{44,143} The program seeks to minimize risk of injury and fatalities associated with age-related fragility. Occupational therapists and trained technicians work with each participant to ensure that he or she “fits” the vehicle properly for maximum comfort and safety.

Arthritis

Arthritis is the most prevalent disease of people over 65 years of age. The pain, fatigue, ROM deficits, diminished strength, and reaction time caused by arthritic conditions can negatively impact driving performance.¹⁵⁴ Depending on the location of joint involvement, arthritis can limit specific driving skills. For example, involvement of the cervical spine can impair head turning and the ability to check

traffic to the side and rear of a vehicle. Clients report difficulties in turning a key, operating switches for the **secondary controls**, entering and exiting a vehicle, managing seat belts, and operating gas and brake pedals. Loading and unloading mobility devices can also prove to be problematic. Strategies to facilitate safe driving in this group can include instruction in proper body mechanics and energy conservation techniques and use of adaptations, including key turners, mirror extensions, and back supports.

Theoretical Constructs

Activity analysis using the Occupational Therapy Practice Framework-2 provides a strong foundation for a thorough driver evaluation. Client factors and performance skills are first assessed in the clinic. The physical context of actual driving conditions encountered during the on-road test provides an opportunity for the therapist to evaluate the integration of performance skills and client factors.

Occupational role theory, which enables a therapist to match activity demands with desired roles, is also helpful in driver assessment. Occupational roles may have specific demands related to transportation equipment and parking environments. A construction site inspector who enters and exits a vehicle several times a day may need to consider driving from a transfer seat or from a wheelchair in a van. A certified public accountant who audits businesses that have parking structures or covered parking may need a minivan that does not exceed certain height restrictions. The older driver may be satisfied with the freedom to drive to church, medical appointments, and the grocery store. In each example, selection of the vehicle and its modifications are impacted significantly by the occupational roles chosen by the client.

Driving Assessment

Clinical Assessment

Clinical assessment is also referred to as a *screening or pre-driving evaluation*. The clinical assessment can be performed solely by the OT or by many members of the rehabilitation team together.^{42,88,122} Its purpose is to build rapport and identify strengths and weaknesses in potential performance skills and client factors related to driving. The clinical assessment begins with a review of medical history, medication and side effects, and episodes of seizure or loss of consciousness (which might include past and present experience with adaptive controls), and a discussion about the purpose of the evaluation. An interview process with open-ended questions often yields greater results and more readily unveils unexpected, pertinent, and critical information that should be pursued further. Open-ended questioning with Jacqueline revealed the lack of a backup transportation plan; this information enabled the therapist to provide appropriate intervention through referral to paratransit services.

Before proceeding with an evaluation, the OT should determine whether a client's condition is stable, improving,

or progressively deteriorating. In progressive conditions, a mobility history should be taken to determine and document the rate of progression. Without this information, it is very difficult to project what the client's future needs for adaptive controls will be. The clinical assessment will then independently assess the individual's performance skills and client factors required for safe driving.

Visual Functioning

A comprehensive vision screening is important because vision is the primary sense used to gather information for driving-related decision making.¹³⁵ Vision testing is completed before other testing to eliminate impaired acuity as a factor. A comprehensive vision screening includes near and far acuity, phoria or alignment, saccades, oculomotor pursuits, ROM, convergence, and field of vision.^{25,39} Glare recovery is relevant for assessment in the older adult; this is a recommended best practice.²⁵

Motor Skills

Muscle strength, active ROM, grip, and reaction time are frequently cited as basic abilities that must be measured.^{25,39,88,94} Research linking crash risk to age-related functional decline has highlighted the importance of neck flexibility for checking the sides and rear of a vehicle, and of sufficient leg strength for controlling the brake and accelerator pedals.⁶⁰ Ability to stabilize and align posture and position by oneself (dynamic and static posture) is also important. The quality of performance skill elements, such as coordination, manipulation, and flow of movement, should also be ascertained.³⁷ Force readings with a torque wrench or a Chatillon scale provide data that facilitate appropriate matching of the client's strength and effort with the activity demands of steering or braking, particularly in more complex modifications for driving.

Cognitive and Visual-Perceptual Skills

Safe drivers must have mental functions to accommodate to a rapidly changing environment by adequately blending cognitive and visual-perceptual abilities. *The Physician's Guide to Assessing and Counseling Older Drivers*⁷ identifies memory, visual-perceptual skills (e.g., visual processing, visual search, visual spatial skills), selective and divided attention, and the executive skills of sequencing, planning, judgment, decision making, language skills, and vigilance as useful for safe driving. Driving places particular demands on attention.⁷ Selective attention, for example, is needed for a person to attend to urgent stimuli without being distracted by unimportant ones. Divided attention is required to focus on multiple relevant stimuli frequently encountered in a complex driving environment. Evaluation of attentional functioning is important in the older driver, as this skill can deteriorate with age. The UFOV³¹ is used to measure aspects of visual attention, including divided and selective attention. Reductions in the useful field of view

have been associated with an increase in vehicle crash frequency. The ability to multitask is a related critical driving skill that requires dividing attention.¹¹⁴ Multitasking is the simultaneous performance and monitoring of two or more equally important activities, such as maintaining lane positioning while turning one's head for a visual traffic check.

Many other cognitive and visual-perceptual tests are appropriate for identifying potential impairments to driving. For instance, the Assessment of Driving Related Skills (ADReS), utilized by physicians to screen older drivers,^{7,113} employs the UFOV, the Trail Making Test, Part B, and the Clock Drawing Test to identify increased cognitive and visual-perceptual risk factors. However, practitioners should be aware that recommendations for driver license status should not be made on the basis of clinical test scores alone. No clear evidence suggests that any one test or group of tests identifies at-risk drivers or accurately predicts driving competence.^{25,30,39,60} Properly used and selected, however, cognitive and visual-perceptual testing helps the driver evaluator identify impairments, improve behind-the-wheel risk management, and plan appropriate treatment for driver rehabilitation interventions.

Vehicle Options

Car Considerations

A basic level of service provided by most driving programs is the car evaluation. A car is generally appropriate if a person is able to enter and exit a vehicle and can load mobility devices into it independently. The standard car recommendation is a midsize vehicle with power steering, power brakes, and an automatic transmission. A two-door car can be advantageous for wheelchair loading by the driver, although some find the larger and heavier vehicle door difficult to manage. Fewer two-door models are being manufactured, resulting in more frequent use of four-door vehicles.

When loading a manual wheelchair into a car is not feasible, a mechanical device such as a car-top or rear bumper loader may provide the driver with some independence. However, this type of equipment has become relatively rare because of the reduced roof surface areas and diminished load capacities of many modern cars. Clients with limited ambulation who use a scooter or wheelchair for long distances may be able to continue to use their standard sedan, sport utility vehicle, truck, or minivan with the assistance of a power hoist to lift the mobility device (Figure 11-24).

Van Considerations

Drivers who depend primarily on a wheelchair most often choose between full-size vans and minivans. Therapists should have an idea of where a client plans to drive, so that the advantages and disadvantages of the two vehicle alternatives in those environments can be discussed. Providing information on the differences between minivans and full-size vans, including accessibility, ground clearance, load

FIGURE 11-24 The Curbsider, by Bruno, hoists a scooter or a fully assembled power wheelchair, up to 250 lb, from the sidewalk and lifts it into the back of a standard minivan.

FIGURE 11-25 A platform-style lift can be located at the side or rear of a van. Additional entry headroom, obtained through a lowered floor, provides client with appropriate visibility when driving from a power wheelchair.

capacity, durability, and cost, enables clients to make educated choices that suit their needs, budget, and lifestyle. In any van, the interplay between a person who drives from a wheelchair and the vehicle is complex. A more skilled evaluation is needed when a person drives from a wheelchair because of the numerous variables that affect equipment selection and driving performance.

An automatic mechanical lift is required to independently enter a full-size van with a wheelchair or scooter.¹¹⁹ Mechanical lifts can be mounted on the rear or side of a full-size van. Platform-style lifts are the only types that comply with Federal Motor Vehicle Safety Standards (Figure 11-25). Minivans should be equipped with fully automatic mechanical side ramps for independent exit and entry (Figure 11-26). Although they have limited interior space,

FIGURE 11-26 Minivan conversion with side ramp access and a lowered 10-inch floor. The ramp angle can be decreased for easier entry and exit.

minivans are appealing to many people because they drive more like a car and get better gas mileage than a full-size van. Also, minivans fit more easily than full-size vans into home and public garages.

Other Vehicles

Sport utility vehicles (SUVs) and trucks, both midsize and full-size, present additional options for individuals who require limited adaptive equipment to drive successfully. Four-wheel drive is a feature that can be included in a modified vehicle at significant additional cost. However, when clients decide on vehicle options besides vans or cars, it becomes more difficult to ensure that the modifications they require to drive safely and independently will be compatible with the chosen vehicle type.

Stationary Assessment

The stationary component involves an examination of the person's habits and routines before starting the engine. Adaptive equipment is set up with the vehicle parked. As needed, the engine is turned on to assess performance skills in steering, acceleration, and braking. Stationary performance alone is inadequate to predict on-road performance or final equipment needs. The purpose of the stationary assessment process is to enable proposed equipment to be verified, modified, or discarded. This process continues until client and equipment needs are thoroughly clarified. If subsequent on-road performance indicates that the activity demands of driving exceed performance skills, the stationary process is repeated using the next level of equipment. This trial-and-error approach is an expected and necessary step in assistive technology evaluation.³²

Pre-driving Habits and Routines

Pre-driving skills that require assessment include the client's mobility in approaching the vehicle, the ability to open and close the door, and the ease of getting into and out of the

driver's seat. The ability to load and unload a mobility device such as a cane, walker, scooter, or wheelchair must also be taken into account. Additional areas for consideration include fastening the seat belt (and chest strap when needed), adjusting the position of the driver seat and mirrors, ascertaining that the dashboard instrumentation can be seen, and inserting and turning a key (or managing keyless entry operation). Adaptive devices used to facilitate independence include adaptive key holders, loops to ease lower extremity management, adaptations to extend reach for wheelchair loading, and modifications for independent retrieval and operation of the seat belt.

Primary Controls

Steering Control Assessment

The first step in the primary control assessment phase is to position the client to maximize motor skill performance before the **primary controls**—those devices that control steering, acceleration, and braking of a vehicle—can be properly addressed. Care must be taken to ensure that the driver is seated squarely in front of the steering wheel to provide optimal mechanical advantage for steering. Positioning is also critical in assisting drivers to withstand the inertial forces caused by braking and turning without falling over and losing control. Trunk stabilization enhances control of the extremities and consequently the primary controls. Poor trunk stability may necessitate that special positioning devices such as an upper torso support or chest strap be employed. Therapists must also consider positioning as it relates to maintaining a functional field-of-view for the driver.²⁹ In a van, the distance from the floor to the eyes should be between 40 and 46 inches to allow an appropriate driver field-of-view. Once postural issues have been resolved, equipment set-up proceeds to the primary controls.

All steering systems include an element of resistance. Automotive manufacturers do not have universal standards for grading resistance. As a result, one car manufacturer's power steering can be as difficult or as easy to turn as another vehicle's manual steering. Knowledge about the trends and patterns in steering system resistance among popular vehicle models is helpful in making appropriate recommendations and achieving desired outcomes. However, it is very difficult to remain current about this type of technology because it changes quickly. Rehabilitation engineers and vehicle modifiers can be a valuable information resource for OTs in this area.

The first step in evaluating steering control is to determine whether a client's motor skills are adequate to turn the steering wheel of his or her proposed vehicle. The upper or lower extremities can be appropriately used for steering. When feet are employed, a specialized wheel is mounted on the floor of the vehicle. Steering competence is demonstrated by having the client slowly turn the steering wheel to the lock position in both directions without exhibiting undue effort or pain. Rapid turning can cover substitution patterns or decreased strength and does not address

FIGURE 11-27 These steering devices accommodate a variety of hand and upper extremity impairments. (Courtesy Mobility Products and Design.)

performance skills adequately or allow motor performance to be analyzed.

If a driver cannot use both hands to steer, a steering device is frequently recommended as an initial step to improve mechanical advantage. One-handed steering by palming the wheel can result in inadequate control, especially during sharp, fast turns and evasive maneuvers. Adaptive steering devices such as a spinner knob, V-grip, tri-pin, palmar cuff, or amputee ring, improve control and speed when turning the wheel (Figure 11-27).⁵⁸ Once the client's performance skills have been well matched to the activity demands of the steering set-up, verification of competence through a dynamic on-road evaluation can begin.

Steering Systems

Steering systems are divided into those that use an OEM steering column, and higher-technology systems in which the OEM steering column is modified or absent. Modifications such as extended steering columns, steering wheels with smaller diameters, and steering adjustments to decrease the strength needed to turn a wheel by 50% or 75%¹⁵³ are compatible with OEM columns. High-technology options offering flexibility for positioning in the vehicle include a horizontal mechanical steering wheel and a 7-inch remote steering wheel. Additional systems allow a driver to steer,

brake, and accelerate using a single vertical column control (Scott System, Scott System Inc., Denver, Colo)⁶² or a joystick (Aevit J Series, Augusta, Me).⁶⁸ Such systems can enable driving with a single limb. High-level systems can change the number of wheel turns from lock to lock to enhance the ability of certain clients to steer. However, it is important to remember that longer, more complex van evaluations and lengthier driver training are needed when high-tech systems such as these are recommended.

Airbag Issues

A critical final step in steering assessment occurred as a result of airbags.¹⁰⁴ The driver airbag is located in the steering wheel hub. Newer vehicles have advanced airbag technologies that tailor airbag deployment to the severity of the crash and thus reduce injury; however, close or direct contact with an airbag module during deployment can still cause serious or fatal injury. The NHTSA continues to recommend that drivers sit with at least 10 inches between the center of their breastbone and the center of the steering wheel.¹⁰⁷ In some instances, wheelchair seated drivers are positioned very close to the steering wheel, so they can reach adaptive equipment. NHTSA will grant permission for installation of an on/off switch to disconnect a driver airbag under certain circumstances.¹⁰¹ These include a medical

condition that places the driver at specific risk and inability to adjust the driver's position to stay at least 10 inches from the steering wheel.¹⁰⁶ Therapists should document the client's distance from the steering wheel.

Accelerator and Brake Controls

In general, only after the stationary steering process is complete does the evaluation proceed to consideration of the accelerator and brake controls. Modified accelerator and brake controls can be installed in most vehicles. Simple modifications such as pedal extensions can compensate for limited reach in short persons. OEM pedals can be extended up to 12 inches. Maintaining an appropriate seated distance from an airbag can often prevent fully reaching the accelerator and brake pedals and has resulted in an increased need for this type of modification.

When right hemiplegia or right lower extremity amputation is present, the right foot is unable to operate the standard pedals. Intuitively, some clients cross over with the left foot to operate the brake and accelerator pedals. This is an unsafe practice because it places the client off-center for proper steering, and the awkward posture involved can cause strain on body structures over time. A left-sided accelerator pedal can be placed to the left of the standard brake pedal to compensate for this condition; however, OTs will need to make sure that the device can be operated reliably.²⁹ The driver must also be educated about the necessity of instructing anyone who will be operating the vehicle (e.g., mechanics, parking attendants) on how to use this modification.

In cases where the lower extremities are not functional for operating foot pedals, a device called a *hand control* can be used. A hand control consists of rods connected to the OEM accelerator and brake pedals. In a right angle push-pull type of hand control, the motion of pulling down at an angle presses the rod attached to the right foot pedal and causes acceleration. Pushing forward depresses the rod attached to the left foot pedal and activates the brake. Depending on style, hand controls utilize various upper extremity movements (rotary, push-pull, push-pull down, or push-rock motions) to activate the brake and accelerator pedals. Hand controls that use a motor to move the pedals are known as *powered controls*.¹⁵³ High-technology accelerator and brake controls have servomotors activated by vacuum, hydraulic, or electronic means. A careful match must be made between the functionality provided by these devices and the client's strength and motor control. These controls are very sensitive; when they are used, postural control is absolutely critical. Inadvertent movements may result in loss of vehicle control (Figure 11-28).

Secondary Controls

Secondary controls are those used to manage the vehicle and to interact with the elements and other roadway users.¹⁵³ A driver must be able to activate four secondary controls at will when the vehicle is in motion: turn signal indicators, horn, dimmer, and windshield wipers.⁹¹ The switches to control these functions can be placed on the hand control itself, or in a spot where they can be controlled through elbow and sometimes lower extremity motions. Some

FIGURE 11-28 Assessment of visual processing, divided attention, coordination, and judgment must be made in the natural driving environment. Performance in complex and faster traffic situations is essential, because activity demands increase with speed and visual clutter.

people lack the motor function to access multiple switches. In such cases, secondary functions can be controlled by a single sequencing switch.

Activation of the switch initiates a tone assigned to a particular function. Releasing the switch activates the function. The transmission, parking brake, heater and air conditioner, and hazard light and headlights can be operated when the vehicle is parked.¹⁵³

On-Road Assessment

Standard of Competence

Once the stationary assessment has accomplished the task of setting the driver up with primary controls, the ability to use these controls must be observed during the actual process of driving. This is commonly referred to as the *behind-the-wheel* or *on-road portion* of the evaluation. The current industry standard is to accept the on-road driving test as the definitive measure of driving competence.^{60,99}

The on-road assessment should take a minimum of 45 minutes. A shorter period is inadequate to make the necessary observations, particularly those required to make a determination about whether the client is able to sustain mental and physical effort during the drive. The on-road assessment should not be longer than 2 hours of actual driving time.

The individual in the role of the driving instructor orients a driver in the use of adaptive driving equipment, maintains vehicle control by intervening for safety when necessary, and directs the route. A method of keeping track of driving performance, such as recording observations of driving errors, is recommended. Criteria for assessing driving performance should reflect physical management of the vehicle, ability to use adaptive equipment, interaction with other traffic, adherence to rules of the road, and safety judgment.^{56,86}

Driving Route

Driving routes used for the assessment should incorporate a sampling of road conditions, traffic patterns, and unusual settings common to the local region. The driving route should allow the driver time to become familiar with the vehicle and adaptive equipment in a low-stimulation environment. This period of learning and accommodation will be longer for the novice or apprehensive driver. Initially the assessment will involve straight-line driving to determine ability to maintain lane position or make accommodations to position. The assessment route should progress through faster and more congested traffic and various dynamic traffic conditions, so that information can be gathered about the driver's performance in a wide variety of conditions (Figure 11-29). *Competence* implies that a client can repeat a performance skill consistently and that his or her

FIGURE 11-29 This client drives a steep mountain pass near his home. During the follow-up evaluation in his new Driving Systems, Inc. (DSI) unilver van, a test drive was performed in nearby foothills to ensure that adjustments were adequate for steep inclines. This essential step identified additional adjustments needed before delivery.

success was not based on the absence of environmental or traffic challenges. Repeated success in executing maneuvers in situations requiring the use of judgment must be demonstrated before competence can be ascertained. Because drivers' skills greatly vary, *bailout points* are needed along the route to give the therapist the option of terminating the on-road assessment. Therapists should always work within a window of comfort and should take clients only in situations in which it is possible to provide override control.

Driver Recommendations and Interventions

Possible Outcomes

The driver evaluation culminates in a decision about driver competency, identification of the necessary adaptive equipment and vehicle, and, when appropriate, a recommendation for the number of driver training hours required to raise performance skill to a safe and independent level. New driver evaluators need to be cautious not to misconstrue new driver or older driver patterns as uncorrectable errors incompatible with driving. Conversely, less-experienced driver evaluators need to weigh errors, especially with neurologically involved clients, in whom consistency of performance can be an issue. Possible outcomes for a driver evaluation are as follows:

1. The client demonstrates driving competence: no adaptive equipment or driver training is required.
2. The client requires changes to achieve driving competence: adaptive driving equipment and/or training is required.

3. The client's performance skills are borderline: an extended evaluation and/or driver training is required.
4. It is not safe for the client to drive at this time: continued therapy or medical intervention and time for additional recovery of function may change outcome. Re-evaluation in 6 to 12 months is recommended.
5. It is unsafe for the client to drive, and there is no potential for improvement.

After the on-road assessment has been completed, the driving team reviews the results with the driver. Asking the client for feedback before reviewing results provides a valuable perspective on his or her insight. Results cannot be shared with family without permission from the client; a verbal agreement from the client to share results should be documented.

Jacqueline was very nervous in freeway situations and made some noncritical errors, but overall, she thought she did well, especially because better positioning in the car seat decreased her shoulder pain. The therapist agreed. A recommendation of 4 hours of driver training was made to focus on defensive driving skills, compensatory strategies for older drivers, use of expanded mirrors, and freeway maneuvers. In this case, the therapist used the ADED Best Practices resources to assist her in formulating the criteria that she utilized in making recommendations for Jacqueline's additional training.

Written Report

The comprehensive driving report should contain a summary of the clinical assessment and driving performance observations and should provide a statement on the client's potential to be a safe and independent driver. It should specify the type of vehicle necessary to accommodate the recommended modifications, dealer sources for providing the modifications, and other pertinent information. Recommendations about the types of **follow-up services** required (e.g., fitting sessions at the selected vehicle modifier) and who is best suited to provide them are warranted. The report should also estimate the amount (duration, frequency, and total length) of driver training needed, should indicate specific areas of emphasis for training, and should provide resources indicating where the training is available.^{25,137,138}

Driver Training

Training in the use of assistive technology, including adaptive driving equipment, is a key component of the process of delivering comprehensive assistive technology services.⁵⁸ Individuals with cognitive and perceptual impairments often need to relearn driving behaviors or to implement compensatory skills to attain consistent driving performance, even though they may not require adaptive

equipment. Extensive training with a focus on vehicle control and recovery, especially in unexpected situations and at high speeds, is essential when high-technology equipment is used. Some clients will require training in their own vehicle, because the unique modifications that they need for driving may not be available in any of the evaluation program vehicles. Depending on each state's requirements, driver training may occur before or after the vehicle is modified.

Follow-up Services

Follow-up services are another important aspect of comprehensive assistive technology service delivery. When adaptive equipment is recommended, a follow-up evaluation ensures that the equipment is positioned and adjusted to meet the client's functional needs.^{25,137} Follow-up services include midfit and final fit sessions for quality assurance and verification of safety. When an adapted vehicle is delivered, this is the first time that the client, adaptations, and selected vehicle have interfaced. Some adjustment is almost always needed to meet functional goals and to have the adaptations perform as envisioned.²³ An on-road session is recommended to ensure that adjustments are adequate for function when dynamic forces involved in driving come into play.

Licensing Assistance

Dealing with licensing situations related to a disability or medical condition can be daunting and intimidating to a client. OTs must be knowledgeable about the licensing practices and protocols in their state. This knowledge enables the therapist to educate and inform the client about the steps for completing the licensing process. Some situations may call for the therapist to provide assistance at the local agency, so the client can obtain or extend a student or special permit. Contact with such agencies requires the written authorization of the client. Only minimal information pertinent to the issue at hand should be revealed. Best Practices include maintaining common agency forms or driver handbook materials in the clinic for distribution to the client as appropriate.²⁵

Driving Retirement

One of the most difficult tasks facing a driver evaluator is notifying a client that he or she is unable to achieve, or no longer retains, the performance skills required for safe and independent driving. Such decisions need to be carefully thought through and then communicated to the driver with compassion and understanding. The AMA refers to the transition from driver to nondriver as **driving retirement**.⁷ Referring the client to the motor vehicle department to exchange the driver license for a photo identification card, which looks like a license, is essential for legal identification

and psychosocial reasons. The therapist can work on alternate community mobility goals when appropriate to maximize independence and well-being.

Educating individuals on alternative means of transportation and immediately providing materials regarding local options can prove helpful at a difficult time. When driving retirement is considered and planned for in advance, as recommended by many agencies, the transition is eased. OTs play a significant role in promoting long-term planning through community mobility interventions with their clients.¹²¹

Jacqueline is not ready to retire from driving; she had competency verified and is receiving intervention for freeway situations. She feels confident and able to address any driving concerns raised by family members. She told her therapist that she shared the good news regarding her driving skills with her family, although not all were convinced. Her therapist encouraged her to rely on the outcome demonstrated by her performance skills and to perhaps begin discussing transportation needs that will arise when she transitions into driving retirement.

Legal Issues and Public Policy

Therapists and physicians need to be aware of their states' laws concerning medical conditions and driving. Most states do not require that medical conditions, seizures, or loss of consciousness be reported to the motor vehicle department.⁸¹ Instead, most rely on voluntary reporting of medical conditions by the driver.^{7,56} Although some states advocate reporting by the family, physician, or law

enforcement officials, not all states provide immunity for such reporting. Once identified to the motor vehicle department, the client undergoes a license review process that varies from state to state; therapists should know their states' policies on graded licensing.

Summary

Community mobility, whether it occurs while accessing a school bus, driving one's own vehicle, or riding in the local senior transport van, is a pivotal IADL. All forms of community mobility have the ability to enable engagement in necessary and meaningful occupations and are thus the concern of OT practitioners, regardless of whether they are generalists or specialists in the practice area. Individual evaluation, with consideration of valued occupational roles and the transportation systems available to a person, provides a foundation for determining the necessary level of intervention. Evidence-based research should be utilized to support practice, but without losing sight of the importance of driving and community mobility for facilitating social participation and involvement in other occupations throughout the lifespan. OTs are challenged to provide driving and community mobility services that will be widely recognized and valued by consumers, communities, and organizations.

Review Questions

1. Define functional ambulation. List three activities of daily living or instrumental activities of daily living in which functional ambulation may occur.
2. Who provides gait training?
3. What is the role of the OT practitioner in functional ambulation?
4. How do OT and PT practitioners collaborate in functional ambulation?
5. List and describe safety issues for functional ambulation.
6. Name five basic ambulation aids in order of most supportive to least supportive.
7. Discuss why great care should be taken during functional ambulation within the bathroom.
8. List at least three diagnoses for which functional ambulation may be appropriate as part of OT services.
9. What purpose does a task analysis serve in preparation for functional ambulation?
10. What suggestions could be made regarding carrying items during functional ambulation when an ambulation aid is used?
11. What is the objective in measuring seat width?
12. What is the danger of having a wheelchair seat that is too deep?
13. What is the minimal distance for safety from the floor to the bottom of the wheelchair step plate?

Threaded Case Study Jacqueline, Part 3

Jacqueline received intervention in private and public transportation arenas. She was referred for a driver evaluation by her primary therapist and is now participating in a paratransit program for respite and a supplemental transportation plan. She was anticipated to require adaptations because of arthritis in her neck, shoulders, hands, and lower extremities: an adaptive key holder, door opener, blind spot mirror, and steering wheel cover improved function by modifying the physical context of her occupations. Jacqueline received training in adaptive techniques for vehicle entry/exit, car transfers, wheelchair loading, and driving performance. She still could use a wheelchair carrier but has chosen to wait because of the cost. Jacqueline's quality of life has been greatly improved through therapeutic intervention in many aspects of her community mobility. She is quite pleased with the driving outcomes achieved with her therapist.

14. List three types of wheelchair frames and the general uses of each.
15. Describe three types of wheelchair propulsion systems and tell when each would be used.
16. What are the advantages of detachable desk arms and swing-away footrests?
17. Discuss the factors for consideration before wheelchair selection.
18. Name and discuss the rationale for at least three general wheelchair safety principles.
19. Describe or demonstrate how to descend a curb in a wheelchair with the help of an assistant.
20. Describe or demonstrate how to descend a ramp in a wheelchair with the help of an assistant.
21. List four safety principles for correct moving and lifting technique during wheelchair transfers.
22. Describe or demonstrate the basic standing pivot transfer from a bed to a wheelchair.
23. Describe or demonstrate the wheelchair-to-bed transfer, using a sliding board.
24. Describe the correct placement of a sliding board before a transfer.
25. In what circumstances would you use a sliding board transfer technique?
26. List the requirements for client and therapist to perform the dependent transfer safely and correctly.
27. List two potential problems and solutions that can occur with the wheelchair-to-car transfer.
28. When is the mechanical lift transfer most appropriate?
29. How is community mobility defined?
30. What are the primary advantages and disadvantages of public and private transportation?
31. What unique qualifications do therapists have, enabling them to address community mobility issues?
32. What basic element of community mobility can be addressed by the therapist?
33. Why are specialized skills needed for driver evaluations?
34. Describe the driving evaluation process and dynamics.
35. What are the four basic components for protecting passengers seated in a wheelchair within motor vehicles?
36. Name four ways the OTA may be used in a driver evaluation program.
37. What are the five Best Practices components in the driver evaluation process?
38. What is the best method to determine driver competency?
39. How long should the on-road evaluation session be?
40. Why are older driver issues of particular interest?
41. What additional credentials can therapists obtain in the field of driver rehabilitation?
42. What is the function of driver training?
43. Why is a follow-up evaluation necessary with adaptive equipment?
44. What legal issues must be considered by a driver rehabilitation therapist?
45. Where can the interested therapist go for additional information on this area of practice?

■ **Learning Objectives** *After studying this chapter, the student or practitioner will be able to do the following:*

1. Justify sexuality as a concern of the occupational therapist.
2. List at least five possible reactions of the person with physical disability to her or his sexuality.
3. List some attitudes and assumptions that the able-bodied population may make about the sexuality of people with physical disability.
4. Discuss how sexuality and sensuality are related to self-esteem and a sense of attractiveness.
5. Define sexual harassment and describe how to handle a situation in which clients harass staff members.
6. Describe the effects that such items as mobility aids and splints can have on sexuality.
7. List signs of potential sexual abuse of adults.
8. List at least two intervention goals designed to improve sexual functioning.
9. Discuss ways in which the occupational therapist can provide a safe environment for discussing sexual issues.
10. Describe how sexual values can be communicated.
11. List at least five effects that physical dysfunction can have on sexual functioning and possible solutions for each.
12. Discuss the potential hazards of birth control.
13. List the potential complications of pregnancy and childbirth for a woman with disability.
14. Discuss methods of sex education.
15. Define PLISSIT.

Threaded Case Study
Shivani, Part 1

Shivani has cerebral palsy. She is 29 years old and has been married for 2 years. She would like to have a child but has some barriers to overcome with this occupation of reproduction. To start with, as she was growing up she was never taught by her therapists, or anyone else, to enjoy her body and never had a role model with cerebral palsy to know if she could have and raise a child. Now she is trying to relax and enjoy sexual activities with her spouse. This has been further complicated by the fact that several people sexually molested her as she grew up (her doctor and a caretaker). Shivani has also found that sex is uncomfortable in the missionary position where she is lying on her back and her husband is positioned on top of her (the only position she is aware of); she feels like a failure as a partner and as a woman. In her culture, she feels that she should not discuss this topic with anyone.

Critical Thinking Questions

Shivani has been referred to your agency.

1. Can she enjoy having sex, get pregnant, and raise a child?
2. Do issues such as sexual positioning, enjoyment of the body, and abuse have anything to do with OT?
3. How would you approach this situation with Shivani and her partner?

Sensuality and sexuality are important aspects of everyone's activities of daily living (ADLs) and directly relate to the quality of each person's life. As an ADL, sexual activity is in the domain of occupational therapy (OT).⁶⁰ Occupational therapists work with clients in all areas related to sensuality and sexuality (Box 12-1). Sexuality is an integral

part of the human experience and is important for self-esteem and self-concept. It includes emotions, feelings, and hopes for the future. Individuals express sexuality in different ways. Sexual expression is not only the sexual act of intercourse but may include talking, touching, hugging, kissing, or fantasizing. Engagement in sexual activities does not always take priority when individuals exhibit so many other problems and deficits related to their disabling condition (Figure 12-1).

Physical limitations may cause the client to question his or her ability to experience sexual pleasure. With the onset of physical disability, the client undergoes a significant change in the commonly held roles and practices of the able-bodied population.^{10,54,65} The individual with a disability may be regarded by able-bodied persons as

FIGURE 12-1 Sexuality and disability.

asexual, or hypersexual, an object of pity, and unattractive.^{3,37,41} Being perceived as unattractive and possibly unlovable can cause the client to believe that he or she can never be intimate with anyone. Holding this belief can lead the client and related others to a sense of despair. McCabe and Taleporos⁴⁴ found that “people with more severe physical impairments experienced significantly lower levels of sexual esteem and sexual satisfaction and significantly higher levels of sexual depression than people who had mild impairments or who did not report having a physical impairment.”

Low and Zubir⁴¹ and Kettl, Zarefoss, Jacoby, et al.³⁵ found that females with acquired spinal cord injuries reported feeling less than half as attractive after they had acquired the disability, even though spinal cord injury is a disability with little observable physical change in body appearance. These studies showed a major decrease in the self-perception of attractiveness.⁴¹ Another study found that with the advent of a disability, males felt a loss of their sense of masculinity and sensed a threat to the male role.⁵³

These are just a few examples of the feelings and perceptions that affect the sensuality and sexuality of the person who has a physical disability. To accomplish comprehensive rehabilitation with the client, the OT and other health professionals must address self-perception, beliefs, and needs related to sexuality. This chapter examines issues related to sexuality and sensuality with physical disability.

Reactions to Sexuality and Disability

The many obstacles encountered by people with disability should not interfere with the expression of sensuous and sexual needs. As an informed professional, each therapist

can help the adult client eliminate unnecessary obstacles, overcome anxieties, and appreciate personal uniqueness. The expression of sexuality or sensuality is a sign of self-confidence, self-validation, and a sense of being lovable. When a person acquires a disability or is born with a disability, he or she can feel less positive about him or herself and less lovable.^{20,52,53}

Sexuality can symbolize how a person is dealing with the world. If a person feels inadequate as a sexual, sensual, and lovable human being, the motivation to pursue other avenues of life can be affected. When an individual has a negative self-image, coping with life’s problems is difficult. Because sexuality is often used as a barometer of how one feels about oneself, it is productive for the therapist to help the client feel as positive as possible about her or his physical and personal qualities. A healthy attitude toward one’s sexuality enhances motivation for all aspects of therapy. The therapist must try to help the client adjust self-perceptions enough to function positively in life.

Sexuality has been found to be a predictor of marital satisfaction, adjustment to physical disability, and success of vocational training. In society, people are often judged by physical attractiveness.⁵⁴ In Western civilization, physical intimacy is closely associated with love. Therefore, if a person perceives himself or herself as incapable of expressing sensuality or sexuality, it is possible that he or she feels incapable of loving and being loved. The majority of people who have had a stroke “reported a marked decline in all measured sexual functions.”^{24,36} Without the capability of loving and being loved, a sense of isolation and of being valueless may ensue.^{6,41,48,52} Adaptive devices such as splints, wheelchairs, and communication aids can be a detriment to one’s perceived attractiveness and sexuality. For example, it may be hard to perceive of oneself as sexual when an indwelling catheter is present or when splints are worn. By discussing the effects of these devices on social interaction, the client can get some ideas about how to handle difficult situations when they arise.^{1,40,48,67}

OT intervention should include goals that facilitate an increase in self-esteem and enable the client to feel lovable. The therapist’s role is to foster feelings of self-worth and a positive body image to help the client engage in occupations and to minimize feelings of worthlessness and hopelessness.^{6,21,41,52,54} Feeling lovable engenders a sense of self-worth, attractiveness, sensuality, sexuality, and being capable of intimacy. Achieving this goal enhances the development of a healthy and realistic life balance (Figure 12-1) in which the client engages in occupations.

Whether sex is still possible is a concern that arises after the onset of physical disability. This concern is often set aside in the immediacy of coping with the adjustment to hospital life and activities that make up the daily routine. However, the concern is not forgotten. A common complaint made about members of the health care team by people with disabilities is that the staff members do not

readily bring up the subject of sexuality and it's not an integral part of the rehabilitation process, treatment plan, or medical appointment. Individuals with disabilities feel that if their sensuality and sexuality are often negated, a significant facet of their personhood is negated. This lack of acceptance causes the person with a disability to lose the feeling that he or she is treated as a whole person. Currently no single health care profession has been designated to address issues concerning the physiological and psychosocial changes related to sexuality following an injury or illness; rather, interdisciplinary team approaches are often used. However, when a single discipline is not designated, then the subject may be left unaddressed.⁶⁵

Often men and women with disabilities have an increased dependence on an able-bodied partner, which results in a decrease in their sex life.¹⁸ One possible explanation is that the able-bodied partner is less inclined to be aroused when he or she has just bathed the partner or assisted the partner with toileting. It is often difficult to transition from caregiver to intimate partner. The therapist must be sensitive to the possibility of these perceptions and help the client deal appropriately with the feelings they evoke.

The client's sense of masculinity or femininity may be threatened by the disability.^{42,53,56} Men who have recently acquired a disability report that they feel emasculated.^{53,56} Feelings of emasculation can be reinforced by physical limitations. For example, lifting weights may no longer be possible, sports participation may not be possible without adaptations, and attendance at sporting events may be limited by lack of access. The necessity to look up at others from a wheelchair and ask for assistance can engender feelings of dependency.

A man with a disability may react to feelings of dependency and emasculation⁵³ by flirting to prove his masculinity. The client may attempt to flirt or make passes at a therapist. Because it is estimated that up to 10% of the population is homosexual,^{22,49} the therapist can expect that at some time clients of the same sex may make sexual advances.

Women experience many of the same feelings but probably interpret and react to them in a different way.⁵ Women with disabilities report feeling unattractive and undesirable. This can lead to despair if a woman feels that she cannot achieve some of her major goals in life. Thus, the female client may flirt to see if she is still attractive to others.

The therapist must realize that the client is seeking confirmation of her or his sexuality. The therapist should not be surprised by flirtations or sexual advances from clients. In response, the OT practitioner should deal with these behaviors and set therapeutic boundaries in a positive and professional manner, but the therapist should not be harassed. All of the therapist's interactions should be directed toward creating an environment that promotes the client's self-esteem, positive and appropriate sexuality, and adjustment to disability.

Ethical Considerations

When responding to the client, the therapist should be alert to the client's current sexuality issues to prevent doing further damage to the client's sense of self. If the therapist rejects or ridicules the client, the client may hesitate to attempt such confirmation of personal attractiveness in future situations in which these behaviors are more socially appropriate. If the therapist rejects the client, the client may assume that if someone who is familiar with persons who have disabilities is rejecting, then one who is unfamiliar with them would not be likely to be accepting either.

Inappropriate sexual advances, sexual harassment, or exploitation of either the therapist or the client cannot be permitted.^{45,59} Behavior is considered harassment when it causes the therapist to feel threatened, intimidated, or treated as a sexual object. If sexual harassment is allowed, it can be damaging to the client and to staff morale.²⁷ The therapist should provide direct feedback explaining that he or she feels offended and that the behavior is inappropriate and must cease. All of the staff members should be informed and develop and implement a plan to modify the client's behavior if it persists.

Therapeutic Communication

Conversations regarding sexuality can be opportunities for discussing personal feelings and perceptions. One way to approach discussion of intimate matters is by asking the female client how she will perform breast self-examination with her disability. A male client can be asked how he will perform self-examination of the testicles. If the treatment facility does not have information about these examinations, the client can obtain them from the American Cancer Society or the local Planned Parenthood Association. Each of these activities falls into the domain of health maintenance and may not have been discussed by other health team members. This interaction will set the stage for discussion of other personal matters, impress upon the client the necessity for concern about personal health, and reaffirm the client's sexual identity.

Clients often feel safe asking the OT about sexual matters related to their disabilities, because the therapist deals with other intimate activities such as bathing, dressing, and toileting. It is also important to discuss sexual hygiene as an ADL. The trust built up in the relationship encourages this communication. The therapist should be prepared with information and resources. The therapist does not need to know everything or be a sex counselor but should see that the client gets the necessary information or referral.

The OT is the most appropriate professional to solve some problems, such as motor performance needed for sexual activity.¹² For example, discussing positioning to reduce pain or hypertonicity or to enable the client to more

comfortably engage in sexual relations will help the client deal with problems before they occur.^{15,38,48}

Shivani, who has hypertonicity, particularly in hip adductors, experiences discomfort in a sexual position in which she abducts her legs during intercourse with her husband. She and her husband have not explored other positions but instead have decreased the number of times they have intercourse during the month. Shivani's sense of failure and feelings of diminished worth as a wife have further affected the intimacy of her marriage.

Approaches to intervention can include individual, partner, or group sessions. The format in which the information is presented can also vary and is dependent on where the individual is physically, cognitively, and emotionally. It is important to provide the information in a way that can be best understood and when the individual is ready to assimilate it. Information can be presented in many ways and may include diverse media such as videos, pamphlets, or booklets. Varied media may be used to address the unique learning style and need of the individual.⁸

During all aspects of the rehabilitation process, the client needs to work on communication with the therapist, staff, and his or her sexual partner. The therapist can facilitate this process simply by giving the client permission to discuss feelings and potential problems, especially sexual problems. The client needs to learn how to accurately communicate sexual needs, desires, and position options to a partner, either verbally or nonverbally, to have a mutually satisfactory sexual relationship.^{19,35} Each client will have unique problems or issues that are related to the nature of the disability. An example is a client with Parkinson's disease in whom the lack of facial expression impedes the nonverbal communication of intimacy. The client can be taught to communicate feelings verbally that were previously conveyed with facial expressions.

OT Practice Notes

Discussion of sexuality is a way to explore feelings of dependency, identity, attractiveness, and unattractiveness.^{35,39} Communication must be established regarding the feelings of sexual role changes. If a client's perceived roles are threatened, this situation should be dealt with as early as possible during intervention. If it is not, the effects could persist throughout the client's life and impinge on occupations important to the client.

Values Clarification

Sexual values of the client, the partner, and the therapist must be examined for the therapist to interact with the client in the most effective and positive manner.^{3,17,42,48,54} Many professional schools do not train health care workers

on the subject of sexuality and disability.^{3,26,56,61} In-service training can be arranged to help the staff be aware of the sexual needs of people with disability.^{23,35} Books, articles, videos, training packets, and online Internet resources are available for professional education.^{9,16,17,56} Sensitivity training for staff is imperative in creating an atmosphere of openness to discussing issues of sexuality. The sexual attitude reassessment seminar (SARS)²⁸ uses lectures, media, and small group discussions to help participants explore their knowledge and beliefs about sexuality. This seminar also describes sexual problems, how they develop, and how education and therapy can help with their clients. At the very least, it's helpful for therapists to participate in available in-services and role playing in order to increase knowledge and comfort in dealing with questions about sexuality from patients and families.

Unless the staff members are educated about the significance of sexuality and related issues, they could have negative feelings about dealing with these matters.^{3,9,61,66} If the therapist is not aware of the thoughts and feelings of all of the individuals involved, the therapist could make incorrect assumptions that have negative results.¹⁵ One of the most direct ways of gaining information is by taking a sexual history.^{15,56,57} The purpose of a sexual history is to learn how a person thinks and feels about sex and bodily functions and to discover the needs of those concerned.^{15,39,56} According to some researchers, many individuals with a disability had a sexual dysfunction before they acquired the physical disability. Taking the sexual history can help to identify such a problem.⁴⁰

Sexual History

When taking a sexual history, the therapist should create an environment that will allow for confidentiality, comfort, and self-expression. In early intervention, the therapist should ask about the client's concerns regarding contraception, safe sex, homosexuality, masturbation, sexual health, aging, menopause, and physical changes.

Box 12-2 lists some questions that could be asked. All questions should not be asked at the same time, nor would all questions be asked of every client.

After taking the sexual history, the therapist can often ascertain whether guilt is connected with the sex act, body parts, or sexual alternatives (such as masturbation, oral sex, sexual positions, or sexual devices). For example, some clients report feelings of guilt or fear in relation to having sex after a heart attack or a stroke—fear that sex can cause a stroke or guilt that it may have caused the first episode. Another fear is that the partner will not accept the presence of catheters, adaptive equipment, or scars. Performance is often an issue. Able-bodied persons and those with disabilities ask questions regarding the sexual ability of the person with disabilities.

The therapist can furnish the necessary information by (1) directing the client to other professionals, (2) providing

Threaded Case Study Shivani, Part 2

The following questions may have elicited important responses from Shivani.

1. How important is sexuality at this time in your life?
From her answer we would find out that Shivani does not feel that it is important to her but that it is for her spouse and to have a child.
2. How would you describe your sexual activities at this time?
We would find out that sex is uncomfortable for her and that she views sex as more of a necessary evil for her.
3. If you could change aspects of your current sexual situation, what would you change and how would you change it?
Shivani may say that she is uncomfortable during sex because she had been molested previously and that sex is physically uncomfortable for her now, which makes her feel like a failure. The therapist may not want to pursue the discussion regarding the sexual molestation and the psychological counseling aspects but may ask for a referral to a psychiatric professional. The physical discomfort may be then addressed. Positions could be found to make intercourse more comfortable and let Shivani feel less like a failure as a partner.

Box 12-2

Questions to Ask in a Sexual History

- How did you first find out about sexuality?
- When and how did you first learn about heterosexuality and homosexuality?
- Who furnished you with information about sexuality when you were young?
- Were you ready for the information when you first heard about sexuality?
- How important is sexuality at this time in your life?
- How would you describe your sexual activities at this time?
- How do you feel sexuality expresses your feelings and meets your needs and those of others?
- If you could change aspects of your current sexual situation, what would you change and how would you change it?
- What concerns do you have about birth control, disease control, and sexual safety?
- What physical, medical, or drug-related concerns do you have relating to your sexuality?
- Have you ever been pressured, threatened, or forced into a sexual situation?
- Which sexual practices have you engaged in, in the past (e.g., oral, anal, and genital)?
- Do you consider certain sexual activities “kinky”? How do you feel about participating in such activities?
- How important do you think sexuality will be in your future?
- What concerns do you have about your sexuality?
- Are there questions or concerns that you have regarding this interview?

magazines and books that discuss the subject, (3) showing movies, or (4) suggesting role models. The therapist must be tactful and remember that the client is probably questioning her or his own values and previous notions about sexuality. Personal care such as toileting, personal hygiene, menstrual hygiene, bathing, and birth control are issues that can evoke reflection on values regarding sex and body image.

Self-care issues, particularly personal hygiene and sexuality, usually are not emphasized enough during acute illness and rehabilitation. Discussing such issues once or twice is not sufficient. The circumstances and environment in which these issues are discussed should also be considered. The therapist must create an environment that will allow personal discussions to occur. A personal conversation cannot take place in a crowded therapy room, during a rushed and impersonal treatment session, or with a therapist with whom a good personal rapport does not exist. Building rapport is a problem in health care facilities in which therapists are frequently rotated or work on a per diem basis.

A discussion of feelings will also help the client explore her or his new body or adapt to ongoing degeneration of the body if there is a progressive disability. These conversations may take place while other therapeutic activities are in progress so that billing insurers for time is not a barrier.

Sexual Abuse

The sexual abuse of adults with disabilities is a considerable problem.^{1,58,61,66} Clients should be made aware of the possibility of exploitation, especially when using the Internet for social networking and online dating sites. Others have reported that medical staff members took inappropriate liberties with them and that personal care attendants, on whom they depended, demanded sexual favors. Clients can and should report such abuse to Adult Protective Services. The therapist also must report cases of suspected sexual abuse. The client may be reluctant to report abuse because of a concern that it will not be possible to get another aide or that, during the time it takes to hire another aide, essential assistance will not be available. These are major problems for a person who is dependent on others for care.

Therapists usually do not suspect caregivers, medical staff, aides, transportation assistants, or volunteers of sexual abuse, but the therapist should be alert to signs of possible abuse even from these sources.⁵⁵ Some individuals prey on adults and children with disabilities and are drawn to the health fields with this motive.¹ The therapist should watch for signs of potential abuse, such as clients usually being upset after interacting with a specific person, caregivers taking clients off alone for no apparent reason, excessive touching in a sensual manner by caregivers, the client being agitated when around a particular individual, and the client being overly compliant with a specific individual.

Ethical Considerations

Therapists must increase their awareness of what constitutes sexual abuse. Children with disabilities have long been expected to undress and be examined or treated as part of their medical care. This treatment is sometimes necessary, but the preferences and dignity of the client should be respected at all times. A person of any age should not be forced to endure humiliation.

The therapy session should help the client develop a sense of personal ownership of her or his body. This goal may be neglected when working with adults and is often neglected in working with children. For example, a child who believes that he or she does not have the right to say no to being touched, who cannot physically resist unwanted advances, and who may not be able to communicate that abuse has taken place is in jeopardy for being a victim.¹

The therapist should ask permission before touching the client and should touch with respect and maintain the client's sense of dignity. If the therapist does not ask permission to touch a client, the client can lose the sense of control over being touched by others. The therapist should guard against communicating this notion to the client.

Naming body parts and body processes is a good way of helping clients take charge of their bodies. Once the body parts and processes are named, using correct terminology rather than slang, the possibility exists for the client to communicate and to relate in an appropriate manner.^{1,14,47,57} The use of the proper terms has the effect of helping the client view the body in a more positive way, whereas slang tends to communicate negative images.⁵⁷

Effects of Physical Dysfunction

Specific physical problems that may create difficulties in sexual performance for people with disabilities and their partners and suggestions for management of the problems are outlined next and summarized in Table 12-1.

Hypertonia

Hypertonia can increase when muscles are quickly stretched. To prevent quick stretching of muscles involved in a movement pattern, motion should be performed slowly. It is advisable to incorporate rotation into the movement to break up the tone. Slow rocking can be used to inhibit hypertonic musculature. Gentle shaking or slow stroking (massage) can also be inhibitory. Heat or cold can also be used to inhibit tone. Clients with hypertonia should review options for different positions in which to have sexual intercourse. Alternative ways of dealing with personal hygiene (e.g., toileting, inserting tampons, gynecologic examinations, and birth control) may also need to be explored in relation to hypertonicity.

Shivani's OT discussed strategies that could be used to relax the hypertonicity in her legs, such as gently rocking her legs side to side while she was seated. Although initially presented as a means to decrease the hypertonicity affecting Shivani's sitting balance when toileting and for personal hygiene during menstruation, this technique also was suggested as a means to relax her legs before intercourse.

Hypotonia

Clients with low muscle tone (hypotonia) need physical support during sexual activity. Pillows, wedges, or bolsters may be used to support body parts, allowing for endurance and protecting the body from overstretching and fatigue. Sexual positions that allow support of the joints involved should be explored. The client and her or his partner should also explore their attitudes about the positions.

Low Endurance

Prolonged sexual activity can be intolerable because of low physical endurance. Some techniques for dealing with low endurance are employing principles of work simplification to sexual activity, using timing to engage in sex when the client has the most energy, and assuming positions in which sexual performance uses less energy.

Loss of Mobility and Contractures

Limited mobility and contractures prohibit many movement patterns and limit the number of positions for sex. Activity analysis must be done to find positions that will allow sexual activity. This system often requires creative problem solving on the part of the client, the partner, and the responsible professional counselor.

Joint Degeneration

Conditions such as arthritis can cause pain, damage to the joints, and contractures. Avoiding stress and repetitive weight bearing on the joints can decrease joint damage. Activity analysis is needed to reduce joint stress and excessive weight bearing on the joints. It is necessary to find a position, such as that shown in Figure 12-2, that takes weight and stress off the knees or hips. This position is sometimes referred to as the missionary position. A position with substantial hip abduction may not be acceptable for

FIGURE 12-2 This position places pressure on a female's bladder and requires hip abduction but little energy expenditure for her. *An excellent discussion of these alternatives can be found in *Sexuality and Disability* 12:1, 1994.

the client, in which case a side-lying position may be more acceptable. If hip abduction is limited, the woman should avoid positions such as those shown in Figures 12-2 as well as Figures 12-5 and 12-9, presented later in the chapter. After Shivani's OT introduced the technique of slow rocking, Shivani asked about other positions that would be more comfortable during intercourse. The OT discussed the possibility of using the side-lying position to decrease the stress on the hip joints and discomfort Shivani experiences during intercourse.

Pain

Pain limits the enjoyment of sexual activities.³¹ Usually at some time of day pain is diminished and energy is at its highest. Sexual activities can be scheduled for such times. After pain medication has taken effect, many people find that sexual activity is possible. Communication between partners is especially important when pain is involved. An unaffected partner who does not understand the negative effects of pain may believe that the affected partner is not considering her or his personal needs. A referral to a counselor who understands the effects of pain or to a pain specialist can help work out emotional and physical aspects of this problem. The OT can help the client think of acceptable ways of meeting the partner's sexual needs without causing pain. Masturbation and mutual masturbation with sexual fantasy are possible ways of meeting sexual needs in these circumstances. In this way the partners are interacting and neither person feels isolated.

Loss of Sensation

The loss of sensation can affect the sexual relationship in several ways. The lack of erogenous sensation in the affected area can block proper warning that an area is being abraded (e.g., the vagina not being sufficiently lubricated) or damaged (e.g., bladder or even bones if the partner is on top and being too forceful). A lack of sensation may be a sign of disruption of the reflex loop responsible for sensation and erections in the male and sensation and lubrication in the female.

Cognitive Impairments

Disabilities such as traumatic brain injury (TBI), multiple sclerosis (MS), and cerebrovascular accident (CVA) may affect sexual relationships and sex drive. Clients may exhibit difficulties with attention/concentration, social communication, decreased awareness, and executive functions such as abstract thinking, all of which can affect relationships and successful sexual interactions.⁷

Emotional and Behavioral Changes

Depression adversely affects sex drive, and with a new onset of a disability there is a high incidence of depression. For example, depression exists in 14% to 61% of persons with TBI and in individuals who have sustained a spinal cord injury.^{11,43}

Aging and Sexuality

With aging, changes take place that can affect sexuality. Menopause and the resulting hormonal changes cause vaginal atrophy in women and slower reactions to sexual stimulation. In the male, greater stimulation may be needed to develop and maintain an erection, and reaction time between erections may be greater. Partners can be informed of ways to increase stimulation and can be helped to understand that it is the quality, not the quantity, of sexual activity that is important in the relationship. The client should be made aware of the maturation process and its normal effect on sexuality so that the disability is not blamed for all of the problems.

Isolation

The environment is composed of objects, persons, and events. In all activities is an interaction between the person and environment. Some of the objects with which people with disabilities interact are wheelchairs, braces, canes, crutches, and splints. These objects are all hard, cold, and angular. They can communicate a hard exterior and a fragile interior and can convey the notion that no softness exists, that it is not safe to hug, and that a person in a wheelchair or in braces or on crutches can get hurt or toppled if touched. As a result of these ideas, the individual with a disability may feel isolated by the appliances.

Some people tend to withdraw from the objects around the client. This may reinforce the client's notion of a lack of sensuousness and increase the client's sense of isolation. Clients often feel isolated and different from the "normal" population.¹⁷ This phenomenon is more common among clients who have been out of the health care facility for a period of time. In the early phases of the disability, the therapist and the client can role-play about how to deal with a new partner or how to explain the equipment used, such as a catheter. This approach may help ease the client's fears and increase the client's comfort with such issues. At the same time, the therapist is communicating that sex may be a possibility in the future. It should be pointed out to clients that at no time in human history have people with disabilities not existed in society, that they are a part of society, and that it is not "abnormal" to have disability. All people who live long enough will acquire a disability to a greater or lesser extent at some time.

Medication

Approximately 20% of individuals experience various side effects from prescription medications. Potential side effects of medication are impotence, delayed sexual response, or other problems. Diuretics and antihypertensives can cause impotence, decreased libido, and loss of orgasm. Tranquilizers, selective serotonin reuptake inhibitors (SSRIs), and antidepressants can contribute to decreased libido and even impotence in some individuals.⁵⁶ Side effects of medication should be discussed with the physician and the pharmacist to see whether medications can be altered or changed. If

they cannot, acknowledging that the problem is organic can be helpful to the client.

Street drugs also have sexual side effects and adversely affect sex drive and desire. For example, methamphetamines and cocaine may have the sexual side effect of decreased interest in sex and difficulty reaching orgasms. Marijuana and alcohol can cause difficulty in obtaining and sustaining erections. Although occupational therapists do not condone usage of street drugs, it is important to consider that it may be part of our client's life and providing education on these side effects is critical.

Performance Anxiety

At times of great emotional stress, a male client may find that the erection is inhibited. This problem can lead to increased anxiety in relation to sexuality and create a cycle of dysfunctional inhibition. It can be helpful for the client and his partner to take the focus off erection and genital intercourse and focus on sensuality and making each other feel good. A massage is one possibility that will allow for more normal physiological reactions. If this approach does not work, a trained counselor may be needed to help the couple deal with the problem, if it has been determined that the problem is not organic in nature.

Skin Care

The person with a disability should be informed that positioning modifications might be needed to protect the skin, prevent skin breakdown, and increase pleasure. If a sexual position causes repeated rubbing on the skin, this friction can cause abrasions and result in skin damage. The therapist and client can discuss methods to prevent the friction—through an alternative position, for example. Pressure on bony prominences or pressure exerted in a specific area by a partner can also cause problems with skin irritation and must be avoided.

Lubrication

Stimulating natural lubrication in female clients is important. It may be overlooked in a woman with paralysis because she may not be able to feel the stimulation or lack of natural lubrication. Stimulation to cause reflexive lubrication should occur even when the woman does not feel it. Without proper lubrication, damage may occur without awareness of the problem. If needed, artificial water-based lubricants (such as K-Y Jelly) should be introduced. The individual should be warned that only water-based lubricants are appropriate because petroleum-based lubricants can cause irritation and can attack latex condoms, causing condom failure. This is a major concern because the female partner is more likely than the male to become infected with the human immunodeficiency virus (HIV) in any given heterosexual encounter.

Erection

Many men regard the ability to achieve an erection as one of the most significant signs of masculinity.³⁹ If awareness of sensory stimulation to the penis is blocked by the sensory

loss associated with paralysis and if the male client does not try to stimulate a reflexogenic erection, he may believe that he is impotent. This is not necessarily true, and the client may go through much needless anguish. The client should be encouraged to explore his body. Rubbing the penis, the thighs, or the anus can be effective ways to evoke a reflexogenic erection. Even rubbing the big toe has been reported by some men with quadriplegia to stimulate an erection. If the normal reflex arc is interrupted, it is usually not possible to achieve an erection, and alternative methods must be explored.

Alternative methods can be forms of sex that do not require an erect penis, such as using a vibrator or trying oral or digital sex. If the client feels that penile intercourse is the only acceptable method, other possibilities do exist.¹³ Injections of hormones that stimulate erections can be used, but this practice may have adverse reactions or lead to problems if the client does not have good judgment or lacks hand dexterity. The use of a vibrator or massager against the penis to help produce ejaculate is sometimes effective and is one of the less invasive techniques.⁵⁷ Surgical implants can be used but have disadvantages, such as the possibility of infection and skin breakdown. With a physician's prescription Viagra, Levitra, and Cialis are among the stimulants that are being developed and may be a possibility for some clients but have some major side effects.

Fertility

Some disabilities may directly impact an individual's ability to biologically become a parent. For example, women who sustain a spinal cord injury (SCI) or traumatic brain injury (TBI) may experience a disruption in their menstrual cycle. This pause may last as long as 6 months after an injury. However, the ability for a woman to have children is not usually affected once her menstruation resumes. It should be noted that depending on the disability, a woman may be subject to certain pregnancy-related complications, and those should be discussed with a physician prior to considering pregnancy. Men with catastrophic injuries or illnesses such as spinal cord injury also experience difficulty with fertility. Typically, the reason for this is the inability to ejaculate during intercourse. Men who wish to father a child do have options, and a fertility specialist should be consulted.

Birth Control

The client should consult with her or his physician in weighing the pros and cons of various methods of birth control. People with disabilities must consider a number of factors when planning birth control.^{12,13,29,38,47} Because most disabling conditions do not impair fertility (especially for women), it is important for the client to be aware of birth control and potential complications of the use of birth control.

Condoms require good use of the hands. An applicator can be adapted in some cases, but someone with good hand dexterity must assemble the device beforehand. Diaphragms

are not very feasible for people who have poor hand function, unless the partner does have hand function and both parties feel comfortable about inserting the diaphragm as part of foreplay. The contraceptive sponge also requires good use of hands.

Using birth control pills can increase the risk of thrombosis, especially when the client is paralyzed or has impaired mobility. If the client has decreased sensation, the intrauterine device (IUD) can result in complications from bleeding, cramping, puncturing of the uterus, or infection. The use of spermicides requires good control of the hands or the assistance of the partner who has normal hand function. The use of nonoxynol 9 has been suspected to increase the risk of HIV transmission and should be avoided.⁵⁰ The injectable type of birth control may allow for easy use but has many of the same side effects as the pill. In using any method of birth control, the client must always be concerned with decreasing the chance of infection and with practicing safe sex.

Adaptive Aids

Adaptive aids may be necessary, especially if the client lacks hand function. One aid is a vibrator for foreplay or masturbation.²⁵ Special devices have been adapted for men and women.^{15,38,47} Pillows may be used for positioning, and other equipment may be used for clients who have special needs. The therapist must prepare the client for the concept of using sexual aids before suggesting the option to the client. For example, the therapist can suggest that the client privately explore the sensation that the vibrator produces in the lower extremities. The client might discover the possible use of the vibrator for sexual stimulation or at least, when told how it can be used, may be more open to the idea of using a vibrator as a sexual aid.

Safe Sex

The issue of safe sex has increased considerably since the advent of the acquired immune deficiency syndrome (AIDS). Safe sex is important to protect against all forms of sexually transmitted diseases (STDs).²⁹ Clients need to be advised that this is an important issue. If there is a sensory impairment in and around the genital area, the person might not be aware of an abrasion or infection. Having any genital irritation or infection allows easy entrance for STDs. The person with disability must be informed of the increased risk for HIV and STDs so that extra caution can be taken.

Hygiene

Catheter care is a concern, especially when hand function is impaired. Questions may be raised regarding how or if a person with an indwelling catheter can have sex. Sex is possible for both men and women, but some precautions should be taken. If the catheter becomes kinked or closed off (which will definitely happen in the case of a catheterized man having vaginal intercourse), pressure should not

be placed on the bladder. The bladder should be fully voided before sexual activity. Urine flow should be restricted for as short a time as possible and no more than 30 minutes. Damage to the bladder and kidneys could result if these precautions are not followed. The client should not drink fluids for at least 2 hours before sex to prevent the bladder filling during this time. Sexual positions that avoid placing pressure on the bladder should be used (Figures 12-3 to 12-10). Many of the same positions can be used if the client uses a stoma appliance.

Women who have various disabling conditions have reported irregular menstrual periods and deterioration of their neurologic condition during menstruation.⁶⁴ Hygiene issues may occur for several reasons. Lack of education, poor hand function, and poor sensation are conditions that may contribute to menses complications. Information regarding toxic shock syndrome should be given to clients who may not feel or be aware of infection. A sanitary napkin or pad requires less fine motor skill and is less dependent on intact sensation than a tampon. Although the client's preferences must be considered, the therapist is responsible for educating a woman regarding the pros and cons of using either a sanitary pad or a tampon during menstruation. Menopause complications may be increased, but this area may need further research.

A person with an impairment of bowel or bladder function may have an occasional episode of incontinence during sexual activities. If the client and the therapist discuss this possibility and how to deal with it, some embarrassment can be averted when it occurs. The client and therapist can role-play to explore various scenarios, such as "You are planning intimacy with a new partner. How will you explain your catheter and appliances to the person?" These may be awkward conversations for the therapist and the client, but

FIGURE 12-3 Vaginal entry of B requires no hip abduction, and hip flexion tightness would not impede performance. Energy requirements for both parties are minimal. Bladder pressure, catheter safety, and stoma appliance safety should not be an issue in this position for B. This position may be recommended if B has back pain or is paralyzed, especially if roll is used to support lumbar spine.

FIGURE 12-4 Partner A needs little hip abduction but good strength. Partner B may find decreased strain on his back. Hip, knee, or ankle joint degeneration would preclude this position for either partner.

FIGURE 12-6 This position keeps pressure off the bladder, lessens the chance of tubing becoming bent, reduces pressure on the back (especially if a small roll is used under the low back), and does not require B to use much energy. The legs do not need to be as high as is shown, but if hip flexors are contracted, this position may be comfortable.

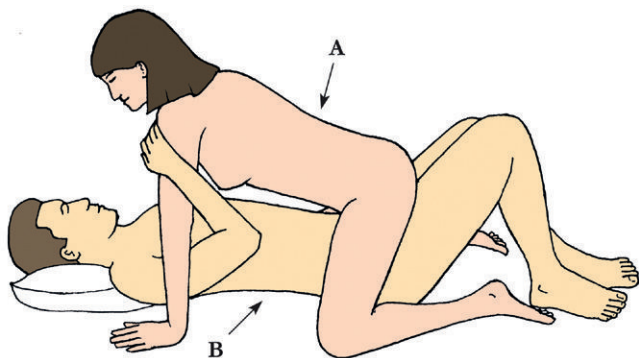

FIGURE 12-5 Person A must have hip abduction, balance, and endurance but pressure is off of bladder and stoma. If a catheter is used, it would be unrestricted. Back pain may be avoided by keeping the trunk vertical. Person B's hip flexors could be contracted. If low back pain is a problem, the legs should be flexed and the roll placed under low back. If the stoma appliance is used, this position would prevent interference. If low endurance is a problem, this position can be used effectively for B.

FIGURE 12-7 Partner B need not expend much energy in this position. Both partners may avoid swayback in this position. Either person may have hemiparesis. Person B will not need hip abduction, and pressure on the stoma bag may be avoided.

FIGURE 12-8 This position can be used if either partner has hemiparesis. If low endurance is a problem, this position can be used. Person A may avoid swayback in this position.

dealing with these issues beforehand is usually easier than waiting for the situation to arise. Such topics must be approached with caution and discretion.

Pregnancy, Delivery, and Childcare

Before becoming pregnant, women must weigh the risks and benefits of pregnancy, childbirth, and childcare. Complications of pregnancy may affect the client's function and

mobility. These include the potential for respiratory or kidney problems. The effect of the increased body weight on transfers, an increased possibility of autonomic dysreflexia, and the need for increased bladder and bowel care should all be considered when pregnancy is contemplated.⁶³

FIGURE 12-9 Partner B can be paralyzed or have limited range of motion. His back may need roll for support, and he must be concerned with pressure on his bladder.

FIGURE 12-10 Rear vaginal entry of B, who does not need much energy because of support and little or no abduction of hips. Flexion tightness of hips does not affect performance. Because of the weight on B's knees, hips, and back, as well as inevitable repetitive movement at hips, this would not be a good position for individuals with back, hip, or knee joint degeneration.

Labor and delivery can present some special problems, such as a lack of awareness of the beginning of labor contractions. Induction of labor may be contraindicated if a person has a spinal cord injury at T6 or above and the medical staff members are not trained to deal with the respiratory problems or dysreflexia that can result. After delivery, the parent with disability will need to have modifications made to the wheelchair. The client may need consultations to achieve an optimal level of function in the parenting role.²⁹

Using Shivani as an example, the therapist may help her with where to find information. Introducing her to sites appropriate for an online search, or encouraging her to contact Planned Parenthood or United Cerebral Palsy to gain the information to make informed decisions would help her locate necessary information. She could also ask these agencies for a list of doctors who have experience with women who were pregnant and have cerebral palsy.

The therapist may then simulate situations during the first year after birth. This may include how to transport an infant, change diapers and dress the child at different stages,

play with the child, bathe the child, and deal with parenting when one has mobility impairments, just to name a few possible scenarios.

Sexual Surrogates

A sexual surrogate is someone trained to work with individuals to help them deal with sexual dysfunction or explore their sexuality. Typically a surrogate will work with a therapist and a client. A sexual surrogate will engage in sexual behaviors with the client, often using specific techniques that have been shown to be effective. The goal is to allow the client to explore aspects of sexual response, sexual feelings, and sexual techniques in a safe environment with a professional who is trained to provide feedback and offer advice.³⁴ The main goal of the interaction is education.

Methods of Education

The following techniques or approaches have been used effectively to deal with the emotional aspects of sex education for people with disability.

Repeat Information

Mentioning sexual issues just once is not enough. Whether they have a disability or not, most people need to hear information more than once. This fact is especially true for people who are in crisis or who are in the process of adjustment to a disabling condition. Too much information, or more than is asked for, should not be offered at one time. Whenever possible, the therapist should try to say something positive in every conversation. Holding out hope for the restoration of function or alternative function is important. The therapist should not assume that the client understands all of the information. To verify that the information is understood, the therapist should invite the client to ask questions and to paraphrase what has been said.

Discovery of the “New” Body

With any disability, the client's body image and perception of the body are altered. In effect, the client has a new body and must find altered ways of moving, interpreting sensations, and performing ADLs. A large part of the therapeutic experience is directed toward helping the client discover how to use this new body as effectively as possible. The therapist can facilitate this discovery of the new body by creating situations that encourage awareness of the body through the input of sensation and function.⁴⁰ The client alone or with her or his sexual partner can accomplish this awareness through exercises that encourage exploration of the body. Exercises such as the gentle tapping or rubbing of a specific area can be developed to see if sensation exists or if the stimulation causes a change in muscle tone. Many people with a disability such as paralysis report that they have experienced nongenital orgasms¹² by stimulating other new erogenous areas, often in the area just above where sensation starts to appear. The therapist may suggest ways

to use this sensation or change in tone in ADLs or may ask the client to think of ways this change in tone could be used, such as triggering reflex leg extension to help with putting on pants. This discussion stimulates problem solving by the client.

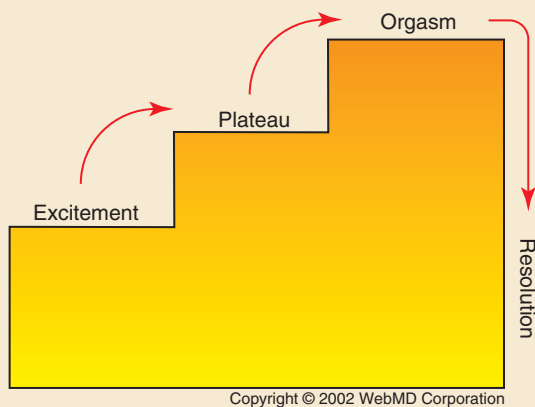

PLISSIT

The acronym PLISSIT stands for permission, limited information, specific suggestions, and intensive therapy. PLISSIT is a progressive approach to guide the therapist in helping the client deal with sexual information.² *Permission* refers to allowing the client to feel new feelings and experiment with

new thoughts or ideas regarding sexual functioning. *Limited information* refers to explaining what effect the disability can have on sexual functioning. An explanation with great detail is not usually necessary early in the counseling process. The next level of information is providing specific suggestions. It may be in the therapist's domain to give *specific suggestions* on dealing with specific problems that relate to the disability, such as positioning. This is the highest level of input the average occupational therapist should attempt without advanced education and training in sexual counseling. *Intensive therapy* should be reserved for the rare client who has an abnormal coping pattern in dealing with

Box 12-3

The Sexual Response Cycle

The sexual response cycle has four phases: excitement, plateau, orgasm, and resolution. Both men and women experience these phases, although the timing usually is different. For example, it is unlikely that both partners will reach orgasm at the same time. In addition, the intensity of the response and the time spent in each phase varies from person to person. Understanding these differences may help partners better understand one another's bodies and responses, and enhance the sexual experience.

Phase 1: Excitement

General characteristics of the excitement phase, which can last from a few minutes to several hours, include the following:

- Muscle tension increases.
- Heart rate quickens and breathing is accelerated.
- Skin may become flushed (blotches of redness appear on the chest and back).
- Nipples become hardened or erect.
- Blood flow to the genitals increases, resulting in swelling of the woman's clitoris and labia minora (inner lips) and erection of the man's penis.
- Vaginal lubrication begins.
- The woman's breasts become fuller and the vaginal walls begin to swell.
- The man's testicles swell, his scrotum tightens, and he begins secreting a lubricating liquid.

Phase 2: Plateau

General characteristics of the plateau phase, which extends to the brink of orgasm, include the following:

- The changes begun in phase 1 are intensified.
- The vagina continues to swell from increased blood flow, and the vaginal walls turn a dark purple.
- The woman's clitoris becomes highly sensitive (may even be painful to touch) and retracts under the clitoral hood to avoid direct stimulation from the penis.
- The man's testicles are withdrawn up into the scrotum.
- Breathing, heart rate, and blood pressure continue to increase.
- Muscle spasms may begin in the feet, face, and hands.
- Muscle tension increases.

Phase 3: Orgasm

The orgasm is the climax of the sexual response cycle. It is the shortest of the phases and generally lasts only a few seconds.

General characteristics of this phase include the following:

- Involuntary muscle contractions begin.
- Blood pressure, heart rate, and breathing are at their highest rates, with a rapid intake of oxygen.
- Muscles in the feet spasm.
- There is a sudden, forceful release of sexual tension.
- In women, the muscles of the vagina contract. The uterus also undergoes rhythmic contractions.
- In men, rhythmic contractions of the muscles at the base of the penis result in the ejaculation of semen.
- A rash, or "sex flush" may appear over the entire body.

Phase 4: Resolution

During resolution, the body slowly returns to its normal level of functioning, and swelled and erect body parts return to their previous size and color. This phase is marked by a general sense of well-being, enhanced intimacy, and, often, fatigue. Some women are capable of a rapid return to the orgasm phase with further sexual stimulation and may experience multiple orgasms. Men need recovery time after orgasm, called a refractory period, during which they cannot reach orgasm again. The duration of the refractory period varies among men and usually lengthens with advancing age.

sexuality. An extensive counseling background is needed to provide intensive therapy.

Activity Analysis

To assess the client's positioning needs, the therapist must analyze the demands of the particular activity. This analysis entails looking at the physical, psychological, social, cultural, and cognitive aspects of the client's functioning. Activity analysis should be implemented using an objective and professional perspective. The therapist must realize that the sex act itself, if one exists, is only a small part of the act of making love and should be treated as just one more ADL that must be analyzed and with which the client needs professional assistance. The therapist must also remember that not all partners had sex on a daily, weekly, or even yearly basis before the onset of the disability. The therapist's values and biases should not be imposed on the client. Same-sex partners, multiple partners, masturbation, or a preference for no sexual activities are some of the client's practices that could evoke bias.

Basic Sex Education

Some clients need basic sex education if they didn't have the information before the onset of disability (Box 12-3). Some clients may not have been informed because of the disability, or they may be misinformed about sexual practices.^{1,12,41,46} Research has shown that people with hearing impairments have substantially less information regarding sex than do those without hearing impairments.⁶² In one study of adolescents with congenital disabilities, it was found that they were misinformed or not informed about sexual issues and that they relied on health professionals and parents to keep them informed.⁴ Women who had not had sex before age 18 years may be less inclined to have sex later if they are not given sexual information.^{19,25,41}

If the OT is not the one to educate the client or the client's partner, the therapist should anticipate the need for information and have resources available for the client to acquire the information. It is not advisable to recommend only books about sexuality and people with disabilities. Such books are useful, but their focus on the disability may be discouraging to some. Books written for the able bodied, such as *The Hite Report on Male Sexuality*,³³ *The Hite Report*,³² and *How to Satisfy a Woman Every Time*,³⁰ can be helpful. These books will not only give the client an understanding of sex, but they will also show the client that he or she is normal, while minimizing the focus on the disability. Excellent books written for individuals with disabilities also can be recommended. Some of these are *Choices: A Guide to Sexual Counseling with the Physically Disabled*,⁴⁷ *Reproductive Issues for Persons with Physical Disabilities*,²⁹ *The Sensuous Wheeler*,⁵¹ *Sexuality and the Person with Traumatic Brain Injury*,²⁷ *Sex and Back Pain*,³¹ *Sexuality and Disabilities*,⁴² *Sexual Function in People with Disability and Chronic Illness*,⁵⁶ and *Enabling Romance*.³⁸

Summary

This chapter began with the case of Shivani and examined some of the possible needs of people with disabilities that affect the ADLs of sexuality. This topic is a powerful one that the OT must deal with in a professional and sensitive manner. We have seen that Shivani can engage in sexual activity, become pregnant, and be a good parent. She may need assistance with finding the better positions to have sex, and she may learn to enjoy her body and sex even though she was abused. All of these issues may be within the role of the OT and should be dealt with to improve the quality of life for the client.

OTs are concerned with the sexuality of their clients because sexuality is related to self-esteem and influences the adjustment to disability and because sexual activity is an activity of daily living. As with other ADLs, a physical dysfunction can necessitate some change in the performance of sexual activities. Education, counseling, and activity analysis can be used to solve many common sexual problems confronted by persons with physical dysfunction.

OTs can provide information and referrals to clients who are concerned with sexual issues. Trained therapists can provide counseling. Issues of sexual function, sexual abuse, and values need to be considered in providing sex education and counseling. Through activity analysis and problem solving, physical limitations that affect sexual functioning can usually be managed. Various sexual practices, modes of sexual expression, and expressions of sensuality are possible. The client needs the opportunity to explore her or his needs and acceptable options to meet those needs. The OT is one of the members of the rehabilitation team who has something to offer the client in the area of rehabilitation and sexuality and sensuality.

Review Questions

1. List at least five areas related to sensuality or sexuality that are usually the concerns of the OT.
2. What are some common attitudes of the able-bodied population about the sexuality of persons with physical dysfunction?
3. How do these attitudes affect the disabled person's perception of her or himself and attitudes toward his or her own sexuality?
4. How is sexuality related to self-esteem and a sense of attractiveness?
5. Describe some typical questions for taking a sexual history. How can these questions be used to clarify values about sexuality?
6. How do mobility aids and assistive devices affect sexual functioning? How can this concern be managed?
7. What are some signs of potential sexual abuse of adults?

8. What are some suggestions for dealing with the following physical symptoms during sexual activity: hypertonia, low endurance, joint degeneration, and loss of sensation?
9. List some medications that may cause sexual dysfunction.
10. Discuss some issues and precautions relative to birth control for the woman with a physical disability.
11. How is a catheter managed during sexual activity?
12. What are some potential problems in pregnancy, delivery, and childcare?
13. Discuss some techniques for educating a person about sexual issues.
14. How should sexual harassment of staff members by clients be handled?

Sleep and Rest

13

JEAN S. KOKETSU

■ Chapter Outline

History of sleep and rest in occupational therapy
Occupational therapy definition of sleep and rest
Need to address sleep in occupational therapy
Need to address rest in occupational therapy
History of sleep in society/cultural influences
Western sleep practices
Brief history of sleep medicine
Sleep disorders
Occupational therapy and sleep
Occupational therapy evaluation

■ Key Terms

Circadian rhythm	Rest
Comorbid insomnia	Sleep
Homeostasis	Sleep architecture
Hypnogram	Sleep efficiency
Insomnia	Sleep hygiene
Non-REM sleep	Sleep latency
Polysomnography	Somnolence
REM sleep	Zeitgeber

■ Learning Objectives *After studying this chapter, the student or practitioner will be able to do the following:*

1. Define normal sleep architecture in the young adult population.
2. Describe how sleep architecture changes across the life span.
3. Describe the difference between sleep and rest.
4. Describe at least five negative consequences of poor sleep and rest on daily occupations.
5. Name at least seven techniques to promote good sleep hygiene techniques that will optimize conditions to facilitate sleep.
6. Describe the role of the occupational therapy practitioner in sleep and rest.

The Occupational Therapy Practice Framework (OTPF) is an official document of the American Occupational Therapy Association (AOTA), the national organization that represents occupational therapy in the United States.⁷ The OTPF is reviewed every 5 years and is considered an evolving document. In the original OTPF,⁵ seven performance areas in which humans engage were identified. The performance areas included activities of daily living (ADL), instrumental ADLs (IADLs), education, work, play, leisure, and social participation. Sleep and rest was organized under the category of ADLs. Several revisions were made in the second

edition of the framework (the OTPF-2) after feedback received from researchers, practitioners, and scholars. One change included a recategorization of sleep and rest.

According to the second edition of the OTPF (referred to as the OTPF-2), sleep and rest is now considered to be one of the eight main areas of occupations in which humans may engage. The categorization of sleep and rest as its own occupational performance area was made for several reasons.

The rationale for this change was that “[r]est and sleep are two of the four main categories of occupation discussed by Adolf Meyer.⁶⁴ Unlike any other area of occupation, all

Threaded Case Study | Mrs. Tanaka

Mrs. Tanaka is a 61-year-old first-grade teacher with a diagnosis of left ischemic cerebrovascular accident (CVA), right hemiplegia, who was born and raised in California. She was admitted to the inpatient rehabilitation unit that specializes in clients with neurologic injuries or events. She is married and lives with her husband of 40 years in a single-story house to which she will return. Mrs. Tanaka has two adult children and three grandchildren. Her 63-year-old husband is in good health and will be her caregiver upon discharge.

Prior to the CVA, Mrs. Tanaka enjoyed working as a teacher and taking care of her grandchildren. Her status at evaluation consisted of the following: right hemiplegia with severe sensory and perceptual motor deficits. Her right arm was edematous, her muscles were hypotonic and dependent for movement. She was able to follow one-step verbal/gestural cues with moderate assistance. She required maximum assistance for bed mobility, dressing, and hygiene and grooming. She was totally dependent for bathing, basic transfers, all instrumental activities of daily living (IADLs), and community mobility. Mrs. Tanaka tolerated 15 minutes of the team evaluation before falling asleep. The prior hospital did not note any sleep disturbance.

The occupational therapist scheduled to see the client at 8 or 9 in the morning to work on activities of daily living (ADLs)

such as bed mobility, transfers, dressing, and hygiene activities. The nursing staff noted that the client had a “rough night” and slept for only 2 to 3 hours. Her hospital roommate complains to the occupational therapist that Mrs. Tanaka snores loudly and tells you that she wants to change rooms as a result. Throughout the day, Mrs. Tanaka was unable to participate in all therapies because of her sleepiness. As the first week of her rehab stay progressed, she continued to have difficulty participating in therapies because of her sleepiness.

The patient, family, and rehab team are concerned about Mrs. Tanaka’s inability to acquire restful sleep at night and to stay awake during the day to fully benefit from therapies and to reach her rehab goals before returning home.

This chapter addresses the area of sleep and rest, two occupational performance areas that are in the domain of occupational therapy practice.⁷

Critical Thinking Questions

1. What is the role of the occupational therapists (OTs) in addressing Mrs. Tanaka’s sleep disturbance?
2. What is sleep and rest, and why do OTs need to address this area of occupation?
3. What can an occupational therapist do to help with Mrs. Tanaka’s sleep difficulty?

people rest as a result of engaging in occupations and engage in sleep for multiple hours per day throughout their life span” (p. 665).⁷ As cited in the OTPF-2,⁷ other rationales included the fact that “[s]leep significantly affects all other areas of occupation. Jonsson⁵⁴ suggested that providing sleep prominence in the framework as an area of occupation will promote the consideration of lifestyle choices as an important aspect of participation and health” (p. 665).⁷

With sleep and rest considered a performance area in the occupational therapy domain, it is appropriate for an occupational therapist to address sleep and rest when treating Mrs. Tanaka.

History of Sleep and Rest in Occupational Therapy

From the earliest published writings in occupational therapy, sleep was considered to be important. In October 1921, Adolf Meyer, presenting a paper at the fifth annual meeting of the National Society for the Promotion of Occupational Therapy (now known as the American Occupational Therapy Association) stated (1922):⁶⁴

There are many other rhythms which we must be attuned to: the larger rhythms of night and day, of sleep and waking hours, or hunger and its gratification, and finally the big

four—work and play and rest and sleep, which our organism must be able to balance in all this is actual doing, actual practice, a program of wholesome living as the basis of wholesome feeling and thinking and fancy and interests. (p. 6)

Despite the founders of occupational therapy considering sleep and rest to be important for a healthy balance in life, the area of sleep and rest seems to have been forgotten in the occupational therapy literature as well as in the profession’s practice.

Green has suggested that occupational therapy has paid little attention to the area of sleep because influential scholars in the field have omitted sleep definitions from classifications of occupations⁴¹ (Table 13-1). Green also noted that occupational scientists are uncertain about whether sleep is considered an occupation. In his research, Green found evidence in the occupational science literature on sleep with respect to time use and of occupational therapists giving advice on sleep. However, he noted, “Coverage has been neither consistent nor comprehensive and it is unclear why sleep has been considered by so few writers” (p. 342).

Howell and Pierce suggested that Meyer’s ideas about the importance of the occupations of sleep and rest were not embraced or further developed in occupational therapy because of the culture’s overemphasis on productivity in industry, business, home management, and even leisure.⁴⁹

■ **TABLE 13-1** | Some Definitions of Occupation and Relationship of Sleep

Author(s)	Definition	Place of Sleep	Comments
Clark et al. (1991)	Chunks of culturally and personally meaningful activity in which humans engage that can be named in the lexicon of our culture. (p. 301)	Definition does not exclude sleep if sleep can be considered a meaningful activity.	Definition of occupation by founders of occupational science.
Hagedorn (1995)	“An occupation is an organized form of human endeavour, having a name and associated role title.” (p. 84)	Sleep is not an occupation but could be an activity in that it “takes place on a specific occasion, during a finite period of time [and] for a particular purpose” and it “results in a change in the previous state of objective reality or subjective experience.” (p. 82)	According to Hagedorn, a person <i>possesses</i> an occupation but <i>performs</i> activities. (p. 79)
Christiansen et al. (1995)	Occupations are the ordinary and familiar things that people do every day. (p. 1015)	This definition could encompass sleep.	Position paper from AOTA states that “while all occupations constitute purposeful activity, not all purposeful activities can be described as occupations.” (p. 1016)
Golledge (1998)	“The daily living tasks that are part of an individual’s lifestyle.” (p. 102)	Terms are defined in the context of therapy, and there is no place for sleep in this taxonomy.	Distinction between purposeful activity, activity and diversional activity.
Carlson and Clark (2001), cited in Larson et al. (2003)	Occupations: —“are units of action with identifiable start and end points” —“are repeatable, intentional and consciously executed” —“tend to be meaningful in the context of a person’s life” —“are intermediate in terms of scope” (between microbehaviours and global life concerns)” —“are labeled by members of a culture” (being customary rather than idiosyncratic) (p. 16)	“Sleep itself would not qualify as an occupation” (p. 16), not being <i>consciously executed</i> , although it appears to meet several other criteria.	It is suggested that it is crucial for occupational therapists to consider the place of sleep in a client’s routine in order to achieve a balanced healthy lifestyle.
Pierce (2001)	“An occupation is a specific individual’s personally constructed, nonrepeatable experience. [It is] a subjective event in perceived temporal, spatial, and sociocultural conditions that are unique to that one-time occurrence. [It] has a shape, a pace, a beginning and an ending, a shared or solitary aspect, a cultural meaning to the person, and an infinite number of other perceived contextual qualities. A person interprets his or her occupations before, during, and after they happen.” (p. 139)	Sleep could not be considered an occupation by this definition, despite meeting some of the criteria, because a person cannot interpret the sleep <i>during</i> the experience.	An activity by contrast is a culturally defined and general class of human actions, for example, play or cooking.

■ **TABLE 13-1** | Some Definitions of Occupation and Relationship of Sleep—cont'd

Author(s)	Definition	Place of Sleep	Comments
Kielhofner (2002)	“Human occupation refers to the doing of work, play or activities of daily living within a temporal, physical and sociocultural context that characterizes much of human life.” (p. 1)	Sleep appears not to be an occupation according to this definition or Kielhofner’s earlier definitions of human occupation (e.g., Kielhofner and Burke, 1985).	Kielhofner noted that all humans exist in a framework of time and that we are moved to fill or occupy time with the things we do. (p. 2)
Christiansen and Baum (2005)	“Occupations are human pursuits that: —are goal-directed or purposeful —are performed in situations or contexts that influence how and with whom they are done —can be identified by the doer and others —have individual meaning for the doer as well as shared meaning with others.” (p. 5)	By these criteria, sleep can be considered an occupation and the authors describe it as such. (p. 10)	

From Green A: Sleep, occupation and the passage of time, *Br J Occup Ther* 71(8):343, 2008.

The authors believe that the Protestant work ethic, Industrial Revolution, and Victorian era all played a role to shape current Western views on restorative occupations. They pointed out that Meyer’s message was “ignored” in Western society because “it is generally believed that valuable time is wasted while sleeping, time that could be spent more productively” (p. 68).⁴⁹

In a review of occupational therapy textbooks published since 1990, Green found that information on sleep was limited.⁴¹ He pointed out, however, that Yasuda⁹⁴ and Hammond and Jefferson⁴⁴ addressed the topic more thoroughly in chapters regarding fibromyalgia and rheumatoid arthritis, respectively. Now that sleep and rest are identified as a separate occupational performance area in the OTPF-2, it is anticipated that educational programs will cover the area of sleep and rest even more thoroughly in their curriculums. Jonsson further suggested that the prominence of sleep and rest as an occupational performance area in the OTPF-2 will highlight the importance of this area of occupation to lifestyle choices for participation and health.⁵⁴

It should be considered that occupational therapists may be so busy helping patients on areas of occupations when the client is awake that focusing on the area of sleep may be given lower priority. For example, the areas an occupational therapist needs to address for Mrs. Tanaka are numerous and can be overwhelming for a novice and even experienced occupational therapist with time pressures for clients to meet functional and other occupational goals.

Given the previously mentioned revision of the OTPF it is expected that the profession will now accord the matter of sleep and rest the attention it deserves as a main area of

occupation. Additionally, educators have a new document by the AOTA, the Blueprint for Entry-Level Education,⁸ which identifies key content areas that occupational therapy students should receive in their education. The topic of sleep and rest was included on the list of occupation-centered factors that should be included in entry-level curriculum content for students.

Occupational Therapy Definition of Sleep and Rest

Sleep

The OTPF-2 defines sleep as “[a] natural periodic state of rest for the mind and body, in which the eyes usually close and consciousness is completely or partially lost, so that there is a decrease in bodily movement and responsiveness to external stimuli.”⁹⁷ During sleep the brain in humans and other mammals undergoes a characteristic cycle of brain-wave activity that includes intervals of dreaming.^{7,86} The OTPF includes in its definition of sleep that consciousness could be “completely” lost. Sleep researcher Mahowald,⁶⁰ however, stated, “There is now overwhelming evidence that the primary states of being (wakefulness, NREM sleep and REM sleep) are not mutually exclusive, but may become admixed or may oscillate rapidly, resulting in numerous clinical phenomena” (p. 159). Coren,²⁶ another sleep scientist, pointed out that at some level our vision, hearing, and sense of touch are still functioning to some extent when asleep. Human sleep is not just the opposite of wakefulness or wakefulness the opposite of sleep.⁶¹ It appears that consciousness is not completely lost during sleep.

Rest

As cited in the OTPF,⁷ rest is defined as “[q]uiet and effortless actions that interrupt physical and mental activity, resulting in a relaxed state” (p. 227).⁷³ According to the OTPF-2,⁷ rest includes identifying a need to rest and relax, reducing involvement in taxing (physically, mentally, or socially) activities, and participating in relaxation or other endeavors that restore energy, calm, and renewed interest and engagement.

Nurit and Michal compared how the literature of the various fields that interact with occupational therapy conceptualize rest.⁷³ Psychology, they pointed out, considers rest a basic human need,⁶² whereas the nursing profession differentiates between physical and mental rest. Various religions and philosophies view rest as important for restoration and focus. The researchers concluded that though the various fields may have different concepts of rest, they all concur with occupational therapy that rest is important for a healthy, balanced life.

Nurit and Michal also reviewed debates surrounding the concept of “bed rest” in medicine;⁷³ they cited that historically rest was highly recommended.¹⁸ They pointed to research that has shown that clients on bed rest, when compared to those clients in ambulatory groups, may experience detrimental effects to their health.³ In this chapter, the focus is on the general concept of rest as opposed to the idea of physician ordered “bed rest” when a patient may not be allowed out of bed for medical or safety reasons.

Sleep and Rest

The OTPF-2 explains that the concept of both sleep and rest “includes activities related to obtaining restorative rest and sleep that supports healthy active engagement in other areas of occupation” (p. 632).⁷ Instead of categorizing the occupations into what she has called “adopted cultural categories” (p. 45)⁷⁸ of work, play, leisure, and self-care, Pierce described the categories of occupation based on how the individual experiences them. She described three categories of occupation as pleasurable, which includes play and leisure; productive, which includes work; and restorative types of occupations, which includes sleep, self-care, and quiet activities.^{77,78} Among pleasurable, productive, and restorative occupations, Howell and Pierce considered restorative occupations as the least recognized.⁴⁹ Pierce stated,⁷⁸ “In our clients, the need for improvements in the restorative quality of their occupational patterns can be critical. Without adequate restoration, productivity and pleasure also remain low” (p. 98).

Need to Address Sleep in Occupational Therapy

It is important to consider that a founding figure of the occupational therapy profession, Adolf Meyer, regarded sleep to be one of the four main areas humans need in

order to function (in addition to work, rest, and play). It is also noteworthy that the OTPF-2 considers sleep a major human occupation.⁷ Perhaps an even more compelling reason occupational therapists should address sleep is because it is an occupation in which every human being across the age span engages or should engage. Out of the eight occupational performance areas under the revised OTPF, it is the only performance area that cannot be performed by someone else or by an alternative means. Though the environment and actions surrounding sleep can be adapted, the act of sleeping itself is the only occupational performance area that cannot be adapted for an individual to function optimally, let alone survive.

Dahl bluntly pointed out that “Sleep is not some biological luxury. Sleep is essential for basic survival, occurring in every species of living creature that has ever been studied. Animals deprived of sleep die” (p. 33).²⁸ As this chapter illustrates, sleep and rest, or lack thereof, affects almost every client population with whom occupational therapy practitioners work and within virtually every setting.

Need to Address Rest in Occupational Therapy

As mentioned previously, rest is considered along with sleep to be one of the primary occupational performance areas according to the OTPF-2.⁷ Rest, however, should not be confused with sleep. According to Dahl,²⁸ “Sleep is not simply rest. Mere rest does not create the restorative state of having slept” (p. 32). Dahl points out that the “fundamental difference between sleep and a deeply relaxed wakefulness is that sleep involves dropping into a state with a relative loss of awareness of and responsiveness to the external world.” If a client such as Mrs. Tanaka “rests” during the day but does not sleep, she will still suffer the loss of sleep with all its unique restorative benefits.

Howell and Pierce discussed the importance of rest in addition to sleep for physical, cognitive, and mental restoration.⁴⁹ They note the uniqueness of individuals in deciding which occupations are restorative and how one person may consider a particular activity to be relaxing and calming while another may not. The authors also point out that occupations that are highly restorative tend to have strong routines of simple and even repetitive nature, are often considered pleasurable and have personal meaning to the individual based on tradition and history with the occupation.

History of Sleep in Society/ Cultural Influences

Howell and Pierce have posited that one of the most significant forces that shape our current view of occupations is the Protestant work ethic,⁴⁹ which developed during the Protestant Reformation in the 1500s. The values of honesty,

thrift, and hard work were developed during this time in Europe when the Protestants separated from the Catholic Church. Leisure was considered a potential temptation into sin.

Coren pointed out that the invention of the light bulb by Thomas Edison served to transform society, making shift work possible throughout the night.²⁶ Prior to the introduction of the modern tungsten filament light bulb in 1913 (an inexpensive and long-lasting bulb), the average person slept 9 hours a night as was documented by a 1910 study.²⁶ The new light bulb served to “free” working people from working in darkness, but, ironically, it may have simultaneously served to decrease the hours of sleep for future generations.

In the 2009 U.S. National Sleep Foundation (NSF) poll,⁶⁹ 1000 telephone interviews were conducted among a random sample of Americans in the continental United States. Respondents were at least 18 years of age and a head of the household. Respondents were asked how many hours of sleep they needed to function at their best during the day. On average, respondents reported needing 7 hours and 24 minutes to function at their best. However, they reported getting an average of 6 hours and 40 minutes of sleep on a typical workday or weekday, almost 2½ hours less than what people reported in 1910. These statistics point to the existence of a culture-wide “sleep debt,” a point of relevance for occupational therapists whose overarching goal is “supporting health and participation in life through engagement in occupations.”⁷⁷

Mrs. Tanaka, whose primary cultural influence is Western, also has beliefs and values about sleep. It is therefore of utmost importance to identify Mrs. Tanaka’s and her family’s beliefs about sleep. Is sleep considered important or a waste of time?

Western Sleep Practices

Sleep behavior among Western industrial societies is distinctive to that culture. In a comparative analysis of sleep amongst industrialized Western society and indigenous cultures, Worthman and Melby pointed out several uniquely Western sleep practices:⁹³

1. Solitary sleep from early infancy, supported by cultural norms and beliefs about risk of overlying need for infant independence of autonomy and need for sexual decorum
2. Consolidation of sleep into a single long bout
3. Distinct bedtimes enforced in childhood and reinforced by highly scheduled daytime hours, for work or school, and mechanized devices for waking
4. Housing design and construction that provide remarkably sequestered, quiet, controlled environments for sleep in visually and acoustically isolated spaces (pp. 104-105)

In contrast, non-Western sleepers habitually engage in co-sleep in shared beds or spaces.⁹³ They also may have a more fluid sleep schedules, more fluid sleep-wake states, and

may fall asleep and remain asleep in more sensorially dynamic settings.

Human beings have a tremendous diversity in sleep patterns and sleep developmental histories based on cultural background and upbringing.⁹³ It is important for occupational therapists to be aware of a client’s sleep history and culture so they can set realistic and meaningful goals for them regarding their sleep. The OTPF-2 acknowledges that client engagement in occupations within cultural contexts influence how the occupation is organized.⁷

It is important for the occupational therapist treating Mrs. Tanaka to find out what her typical sleep habits were prior to the stroke. Did she sleep in her bed alone or with her husband? What time did she normally go to bed and wake up? Did she usually take naps? What habits or routines did she have before going to sleep or upon waking up? Did she experience interruptions during sleep such as getting up to go to the bathroom? What kind of bed did she sleep on? What are her sheet and pillow preferences? Was there noise in the room where she slept? What are comfortable light and temperature levels for her?

Brief History of Sleep Medicine

Sleep medicine as a medical specialty is relatively new. William C. Dement, a pioneer in sleep medicine himself, considers Nathaniel Kleitman, a physiologist who started studying sleep in the 1920s, as the first to devote his professional life to the study of sleep.^{29,30} Kleitman and Aserinsky first started describing rapid eye movement (REM) sleep in the early 1950s with overnight electroencephalograms (EEG) first being reported in the late 1950s by Dement and Kleitman.³¹ In 1965, sleep apnea was discovered in Europe,³¹ and in 1970, Dement founded the first sleep disorders center at Stanford University Hospital. The 1970s saw a proliferation of the opening of sleep disorder clinics. Since that time, sleep medicine has become a specialty in medicine, scholarly journals focusing on sleep were launched, national and international organizations focused on sleep research and education were founded, and a congressional commission focused on sleep was mandated.

Definition of Sleep According to Sleep Medicine

Behavioral Definition

Carskadon and Dement gave a behavioral definition of sleep: “sleep is a reversible behavioral state of perceptual disengagement from and unresponsiveness to the environment” (p. 13).²¹ Sleep also occurs naturally and periodically.²⁹ Sleep is usually characterized by closed eyes, postural recumbence (lying down), and behavioral quiescence. Other sleep behavior such as sleeptalking and sleepwalking may occur.²¹

Scientists describe several discrete stages of sleep based on brain wave patterns and eye and muscle activity. The two major types of sleep are non-REM (or quiet) sleep and REM sleep.³³ The two states (NREM and REM) exist in virtually all mammals and birds and are as distinct from each other as sleep is from the waking state.²¹

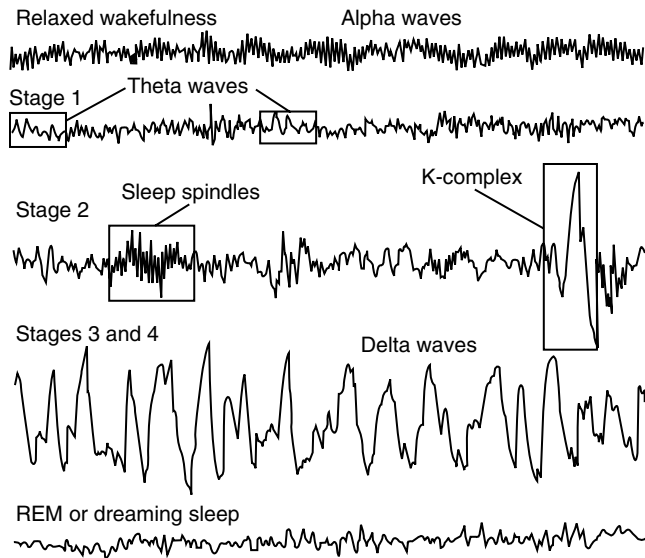

FIGURE 13-1 Brain waves recorded on an EEG to identify stages of sleep.

(From Epstein LJ, Mardon S: *Harvard medical school guide to a good night's sleep*, New York, 2007, McGraw Hill.)

NREM sleep accounts for 75% to 80% of total sleep time in young adults and is usually divided into four stages (S1, S2, S3, S4). The stages are defined by brain wave patterns from an EEG. The EEG pattern in NREM sleep is commonly described as synchronous, with characteristic waveforms such as sleep spindles, K-complexes, and high-voltage slow waves (Figure 13-1).

Conversely, REM sleep, accounts for approximately 20% to 25% of total sleep time in young adults and is defined by EEG activation, muscle atonia or paralysis, and occasional bursts of rapid eye movements.²¹ REM sleep is associated with dreaming. This is based on vivid dream recall reported after approximately 80% of arousals from this state of sleep.³¹ Spinal motor neurons are inhibited by brain stem mechanisms that suppresses postural motor tonus during REM sleep. It is believed that the body is paralyzed during REM sleep to protect dreaming individuals from physically acting out dreams and injuring themselves.

Sleep Architecture

Polysomnography

A polysomnograph (PSG) is a continuous recording of specific physiologic variables during sleep. The PSG is typically performed at night during a sleep study in a sleep clinic. The PSG quantifies sleep and includes an EEG, which measure brain waves, an electromyogram (EMG), which measures muscle activity, and an electrooculogram (EOG), which measures eye movements.⁹⁵ Young et al. pointed out that a PSG also includes an electrocardiogram (EKG) and measures airflow, oxygen saturation, and body position.⁹⁵

Epstein and Mardon described how the sleep stages are charted on a diagram (called a hypnogram) made from the data collected from the PSG;³³ the chart resembles a city

FIGURE 13-2 Sleep architecture. Resembling a skyline, this hypnogram charts the sleep stages during an overnight sleep study. This hypnogram illustrates a typical night's sleep.

(From Epstein LJ, Mardon S: *Harvard medical school guide to a good night's sleep*, New York, 2007, McGraw Hill.)

skyline and is referred to as “sleep architecture” by sleep experts (Figure 13-2). A client’s sleep architecture describes the details of an individual’s sleep after an overnight recording of EEG, EOG, and EMG. The hypnogram shows the following:²⁹

- Time needed to fall asleep (“sleep latency”)
- Sequence of sleep stages
- Time spent in each stage of sleep
- Total sleep time
- Number and length of nighttime awakenings

Progression of Normal Sleep

Normal young adults first enter sleep through NREM sleep with REM sleep occurring 80 to 100 minutes afterward. Throughout the night in approximately 90-minute periods, cycles of NREM and REM sleep alternate with progressively increasing periods of REM sleep.²¹ Box 13-1 lists the general stages of sleep with descriptions of bodily functions during the stages.^{21,33,45,48,83}

Sleep across the Age Span

Research shows that age is the strongest and most consistent factor that affects sleep stages (Figure 13-3).^{21,76} The biggest difference in sleep stages is in newborn infants who enter from wake to sleep through the REM phase for the first year of life. Infants also cycle between REM and NREM, but they cycle through the phases in 50 to 60 minutes instead of the approximately 90 minutes in adults. Deep or slow wave sleep (SWS) is maximized in young children but decreases markedly with age in quantity and quality. For example, children may be very difficult to arouse when they are in deep SWS in the first cycle, whereas an older adult may be easier to awaken in that phase.

Adolescence

Although this book focuses on adults, it is felt that a discussion of adolescents is warranted because teenagers (especially older teens) may be treated in traditionally adult settings such as inpatient rehabilitation units, acute care,

Box 13-1

Stages of NREM and REM Sleep

NREM Sleep

Stage 1 (1-7 minutes)

Considered transitional wakefulness to sleep onset or to REM sleep. Body temperature begins to drop, muscles start to relax, eyes may move slowly from side to side. EEG shows brain waves slowed to four to seven cycles per second, called “theta” waves. You can usually easily wake someone in this phase by tapping him or her or softly calling his or her name (low arousal threshold). However, everyone experiences stage 1 differently. If awakened in this stage, one person may say he or she was asleep while another may only say that he or she was drowsy. A common sign of severely disrupted sleep is an increased amount and percentage of sleep in this phase.

Stage 2 (10-25 minutes)

Follows stage one sleep. Eyes aren’t moving much, heart rate and breathing are slower than when one is awake. This is the first stage of established sleep. Brain waves are irregular with EEG showing intermediate-sized brain waves with brief bursts of fast sleep spindles or K-complexes that occur about every 2 minutes. Overall, more intense stimulus is required to arouse someone in this stage (higher arousal threshold). In the later phases of this stage, the EEG shows high-voltage slow wave activity. May overall comprise half the night.

Stage 3 (usually only a few minutes)

EEG shows slow wave activity for >20% of time <50% of time. For third and fourth stage, breathing slows and becomes more regular, and blood pressure and pulse fall to 20% to 30% of waking state.

Stage 4 (20-40 minutes in first cycle)

EEG shows that >50% of time is in the slow wave activity. Breathing is slow and regular. It takes more stimulus to wake someone in this phase.

REM Sleep

REM (in the first cycle: 1-5 minutes, increases up to 30 minutes)

Body temperature, blood pressure, heart rate, and respiratory rate all increase and are often irregular. Clitoris and penis may become erect. EEG shows dramatic decline in amplitude, which resembles the waking state. Thermoregulation is severely inhibited. Motor neurons are inhibited resulting in major muscles being paralyzed except the diaphragm and ocular muscles.

Note: When stages 3 and 4 are combined, the result is referred to as “slow wave sleep” (SWS), “delta sleep,” or “deep sleep.” See Figure 13-1 for brain wave patterns during sleep. SWS is considered the most restorative stage of sleep for physiologic repair, whereas REM sleep is believed to be necessary for memory consolidation.⁴⁵

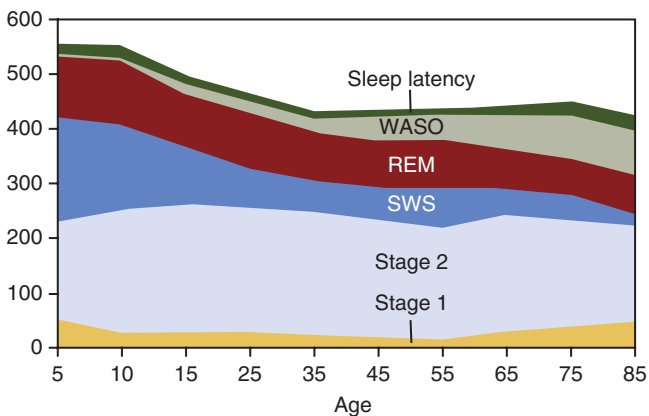

FIGURE 13-3 Time is measured in minutes and looks at sleep latency (the time it takes to fall asleep), wake time after sleep onset (WASO), REM, SWS, and stage 1 and stage 2 sleep in terms of age. Note that as we age it takes longer to fall asleep (sleep latency), deep sleep decreases, and stages 1 and 2 increase. Also note that SWS decreases markedly during adolescence. As we age, night awakenings (WASO) also increase.

(From Ohayon M, Carskadon MA, Guilleminault C, et al: Meta analysis of quantitative sleep parameters from childhood to old age in healthy individuals: developing normative sleep values across the human lifespan, *Sleep* 27:1255-1273, 2004.)

burn unit, home health, and hand therapy to name a few. Contrary to popular belief, teenagers require more sleep than adults. As cited by Carskadon,²⁰ evidence shows that teenagers need at least 9 to 9.25 hours of sleep a night to maintain optimal alertness.²² Teenagers also have been shown to have a phase delay in the circadian timing system, which means that their biological clocks alert them to stay up late and sleep in later (e.g., sleep from midnight to 9 a.m.).³³ These are important considerations to think about in occupational therapy practice in terms of scheduling.

Adulthood

From age 20 to 60, sleep patterns don’t change as rapidly as during childhood. However, there are consistent trends that occur in sleep patterns such as decreased sleep efficiency, decreased time in the restorative deep sleep, as well as easier arousal during the deep sleep phase (Table 13-2). After age 60, the sleep trends of adulthood continue.³³ A hallmark of aging is an increased time spent in stage 1 of NREM sleep and a decreased percentage of time in stages 3 and 4, particularly in men. Sleep efficiency also decreases as one ages. Sleep efficiency is measured by dividing the actual time one is asleep by the amount of time one is in bed. Sleep efficiency at approximately age 45 is 86% and

TABLE 13-2 Sleep Changes with Aging

	Age 20	Age 40	Age 60	Age 70	Age 80
Sleep latency	16 minutes	17 minutes	18 minutes	18.5 minutes	19 minutes
Total sleep time	7.5 hours	7 hours	6.2 hours	6 hours	5.8 hours
Percentage of time in stage 2 sleep	47	52	53	55	57
Percentage of time in deep sleep	20	15	10	9	7.5
Percentage of time in REM sleep	22	21	20	19	17
Sleep efficiency	95	88	84	82	79

Data from Epstein LJ, Mardon S: *Harvard medical school guide to a good night's sleep* (p. 43). New York, 2007, McGraw Hill, p. 43; and Ohayan M, Carskadon MA, Guilleminault C, et al: Meta analysis of quantitative sleep parameters from childhood to old age in healthy individuals: developing normative sleep values across the human life span, *Sleep* 27:1255-1273, 2004.

declines to 79% for those over 70. Brief arousals are also more common with the elderly. Older adults may also have an advanced sleep phase, meaning that they may get sleepy in the early evening and have a tendency for early morning awakening.

Circadian Rhythm and Homeostasis

The timing of human sleep is regulated by two systems in the body: the circadian biological clock and sleep/wake homeostasis.

Circadian rhythms are approximately 24-hour cycles of behavior and physiology that are generated by biological clocks (pacemakers or oscillators).⁶⁶ The internal biological clock regulates the timing and periods of sleepiness and wakefulness, temperature, blood pressure, and the release of hormones throughout the 24-hour day without need of outside cues for the clock to persist. However, environmental stimuli known as zeitgebers or “time cues” help to synchronize that internal clock to the 24-hour day. Light is the most dominant zeitgeber for most species,⁶⁶ with bright light having the ability to shift circadian rhythms.¹⁴

The master circadian (24-hour) clock is located in the suprachiasmatic nucleus (SCN) in the hypothalamus of the brain and dictates when we feel sleepy and when we feel most awake. Melatonin, a naturally occurring hormone, is inhibited by light. It is secreted by the pineal gland at night, which induces sleep and has the ability to synchronize circadian rhythms (Figure 13-4).⁷⁹

The circadian rhythm for sleep and wakefulness is bimodal, with the strongest desire to sleep between midnight and dawn and in the midafternoon (Figure 13-5).^{33,67} This explains why people have the most difficult time staying awake between 2 to 4 in the morning and why they feel most sleepy in the afternoon after lunch. If one is sleep deprived, he or she will feel sleepier during those afternoon dips in circadian rhythm than if he or she had sufficient sleep. On the other hand, if one is sleep deprived and has

FIGURE 13-4 The sleep/wake control center is located in the suprachiasmatic nucleus in the hypothalamus. This “pacemaker” regulates the circadian rhythm of sleep and wakefulness.

(From Epstein LJ, Mardon S: *Harvard medical school guide to a good night's sleep*, New York, 2007, McGraw Hill, p. 21.)

been awake for a long time, he or she may have difficulty falling asleep during those clock “alerting” times. This may explain the quandary of the world traveler who has flown through many time zones and desires to sleep but is unable because his biological clock is telling his body to stay awake.

As cited by Czeisler, Buxton, and Singh Khalsa,²⁷ humans can override the signals of the circadian and sleep-wake system if they have urgent matters to attend to such as studying for a final exam. The invention of artificial light and alarm clock contribute to human need (or desire) to override the biological clock simply because they can or because of societal and cultural pressures to do so.

FIGURE 13-5 The circadian rhythm of sleep and wakefulness has two peaks of sleepiness during the 24-hour day. These peak times of sleepiness are between midnight and dawn (larger peak) and in the afternoon after the typical lunchtime.

(From Epstein LJ, Mardon S: *Harvard medical school guide to a good night's sleep*, New York, 2007, McGraw Hill, p. 20.)

All phases of normal sleep are considered to be under homeostatic control (homeostasis) or the tendency to maintain equilibrium. The longer one is awake or deprived of certain sleep stages, the greater will be the drive to obtain that lost sleep or stage.⁸⁸ Stated differently, as soon as one awakens, the sleep debt starts to accumulate. This sleep/wake homeostasis creates a drive that balances sleep and wakefulness.

What Is Considered “Adequate Sleep”?

Determining what is considered adequate sleep varies widely based on age, genetic, and many other factors.²¹ The National Sleep Foundation recommendations are presented in Table 13-3.

Sleep Disorders

Many sleep disorders have been researched and identified by sleep medicine researchers. Only the more common sleep disorders are reviewed in the chapter.

Insomnia

In general, insomnia is defined as repeated difficulties with initiating sleep, difficulty maintaining sleep, awakening earlier than desired, or having poor quality sleep that is not restorative.³² Insomnia is not considered a disease but is considered a complaint. Insomnia is the most common sleep disorder and in isolation affects 30% to 50% of the general population with 9% to 15% of those reporting impairment in daily activities as a result.³² Risk factors include advancing age, being a female, and having psychiatric or medical problems. The consequence of insomnia is impaired cognition, fatigue or tiredness, depressed mood or irritability, and impaired work or school performance.⁵⁸ Comorbid insomnia refers to clients who have a medical or

TABLE 13-3 | How Much Sleep Do You Need?

Age	Sleep Needs
Newborns (1-2 months)	10.5-18 hours
Infants (3-11 months)	9-12 hours during night, and 30-minute to 2-hour naps one to four times a day
Toddlers (1-3 years)	12-14 hours
Preschoolers (3-5 years)	11-13 hours
School-aged children (5-12 years)	10-11 hours
Teens (11-17)	8.5-9.25 hours
Adults	7-9 hours
Older adults	7-9 hours

Box 13-2

Medical Conditions Comorbid with Insomnia

These are common medical conditions that occur with symptoms of insomnia:

- Cardiovascular disease (congestive heart failure and stroke)
- Pulmonary disease (asthma, chronic obstructive pulmonary disease)
- Gastrointestinal conditions (peptic ulcer disease, gastroesophageal reflux disease)
- Endocrine conditions (diabetes mellitus)
- Renal (renal failure)
- Neurologic conditions (Alzheimer’s, Parkinson’s disease)
- Pain from any source (arthritis, fibromyalgia)
- Urologic conditions (nocturia)
- Perimenopause and menopause
- Cancer

From Kryger M, Roth, T: Insomnia. In Kryger, MH, editor: *Atlas of clinical sleep medicine*, Philadelphia, 2010, Saunders Elsevier, p. 102.

psychiatric diagnosis but also have symptoms of insomnia. Box 13-2 lists medical conditions that frequently have comorbid insomnia. These are common medical conditions that occur with symptoms of insomnia.⁵⁸

Obstructive Sleep Apnea

Obstructive sleep apnea (OSA) can be a serious medical condition that is estimated to affect 18 million adults in the United States.³³ OSA is twice as common in men than in women prior to age 50 with prevalence in the genders

FIGURE 13-6 CPAP machines have dramatically decreased in size since they were first introduced.

■ **Box 13-3**

Symptoms of Obstructive Sleep Apnea (OSA)

- Snoring
- Witnessed apnea
- Excessive daytime sleepiness
- Morning headache
- Dry throat in the morning
- Depressive symptoms
- Erectile dysfunction
- Insomnia
- Impaired vigilance and memory

equalizing with age.⁴⁷ OSA is one of several sleep-related breathing disorders (SRBD) that doctors treat. In OSA the airway becomes blocked when a portion of the individual’s airway slackens, collapses, and closes off the airway blocking airflow. This causes the person to stop breathing then awaken (though not usually fully wake up) throughout the night, sometimes hundreds of times. Apnea is defined as a complete cessation of airflow for a minimum of 10 seconds whether or not there is oxygen desaturation or fragmented sleep. Hypopnea (shallow breathing) is defined as airflow being decreased by 30% or more with oxygen desaturation of 3% to 4%.⁴³ Box 13-3 list symptoms of OSA. This constant awakening throughout the night can lead to severe daytime sleepiness and fatigue. Furthermore, the decrease in oxygen levels throughout the night can cause increase in blood pressure and can lead to cardiovascular disease.³³

Currently, OSA is typically treated with a continuous positive airway pressure (CPAP, pronounced “C-pap”) device (Figure 13-6). The client is fitted with a mask attached to a hose and onto a generator that provides continuous flow of pressurized air through the nose to keep the airway open while the client sleeps. A variety of masks (Figure 13-7) exist, but there are three general types: nasal mask, nasal pillows, and full face mask (Figure 13-8). CPAP has been found to be effective and can be critical to decrease blood pressure in some patients.⁵² However, up to 50% of clients may be noncompliant.⁶⁹ Other treatments for OSA include oral appliances or dental devices and surgery.⁴⁷

If untreated, OSA can have severe adverse effect on a client’s functioning throughout the day. With sleep chronically deprived, daytime function is affected by slowed thought processes, forgetfulness, slowed responses, and difficulty concentrating.⁹⁰ Clients who have sustained a CVA and have been treated in a hospital rehabilitation program were found to have comorbid SRBD that predicted a poorer outcome on functional recovery rate.²³ Researchers suspect that two processes contribute to decreased cognitive functioning in patients with OSA: nocturnal hypoxia (decreased oxygen to the brain) and fragmented sleep. Furthermore, as a group, OSA clients’ risk of motor vehicle accidents is increased twofold. Research has also shown evidence that sleep-disordered breathing precedes stroke and may contribute to the development of stroke.⁵⁵

Considering the functional and cognitive impairments that can result from OSA, it is important for occupational therapists to query clients about their sleep when evaluating clients who may have a secondary diagnosis of OSA or have

FIGURE 13-7 This is a small sample of masks and headgear that are available from several manufacturers. Three general types of masks are used. The two on the right are nasal pillow-type masks where prongs are inserted into the nostrils. In the middle are two full face masks, and to the left are two nasal masks. The bottom nasal mask is for a child.

FIGURE 13-8 This man is using a full face mask that fits over both the nose and the mouth and is useful for “mouth breathers” like this client, who needed it to treat severe sleep apnea.

(From Hayes D Jr, Phillips B: Sleep apnea. In Kryger MH, editor: *Atlas of clinical sleep medicine*, Philadelphia, 2010, Saunders Elsevier, p. 190.)

symptoms that may indicate an SRBD and referral to a physician. The functional-cognitive impairments may impact client follow-through on home programs, safety, and ability to meet goals, and they can result in decreased quality of life.

Since the mid-1990s it has been known that 60% to 70% of all stroke patients exhibit sleep-disordered breathing

(SDB) as defined by an apnea-hypopnea index (AHI) of 10 episodes per hour.¹³ Could it be that Mrs. Tanaka has a history of an undiagnosed SRBD? Or is the sleep disturbance the result of the CVA and location of the brain insult? Or is poor sleep hygiene in the hospital the biggest contributor to Mrs. Tanaka’s sleep issues? It is critical for the occupational therapist treating Mrs. Tanaka to keep the physician informed about the client’s sleepiness during treatment and her loud snoring, both of which can be indicators of OSA.

Restless Legs Syndrome

Restless legs syndrome (RLS) is a common disease that affects a client’s ability to fall asleep and stay asleep.¹¹ RLS affects 10% of adults in the United States with prevalence increasing with age. The four criteria for the diagnosis are the irresistible urge to move the legs due to a creepy crawly sensation when going to sleep, irresistible urge to move the legs, improvement of symptoms with moving legs, and nighttime worsening of symptoms (Figure 13-9).^{4,11,89}

Many clients with comorbid conditions associated with RLS are treated by occupational therapists in inpatient, outpatient, home health, nursing home, and other settings (Figure 13-10). RLS symptoms can occur anytime in the day during prolonged immobilization (e.g., long car drive), but they typically occur in the evening with increasing symptoms until bedtime. The urge to move the legs results in insomnia, effects of which can be detrimental to occupational performance (Figure 13-11).

It is believed that RLS is related to dopamine deficiency with other hypotheses including brain iron deficiency. Current nonpharmacologic treatment includes encouraging

FIGURE 13-9 Essential criteria and core symptoms for RLS.
 (Cited in Avidon AY: Restless legs syndrome and periodic limb movements in sleep. In Kryger MH, editor: *Atlas of clinical sleep medicine*, Philadelphia, 2010, Saunders Elsevier, p. 115.)

alerting (mentally challenging) activities, which have been found to relieve RLS symptoms, as well as avoidance of caffeine, alcohol, and nicotine.¹¹ With focus on occupation and wellness, these are certainly areas in which occupational therapy practitioners can provide treatment.

Periodic Limb Movement Disorder

Periodic limb movement disorder (PLMD) is frequently confused with RLS but is a different condition though they can coexist. PLMD affects up to 34% of patients over 60 years of age with prevalence increasing with age. PLMD can only be definitively diagnosed with an EMG and a sleep study/PSG. In this disorder, a client has periodic episodes of repetitive and stereotyped movements of the limbs (arms or legs), which the client cannot control, during sleep. This results in client arousals or awakenings during sleep, which the client often doesn't recognize. The "creepy crawly" sensations present in RLS do not exist in PLMD. When this condition is severe, clients experience excessive sleepiness, which can affect daytime functioning.¹¹

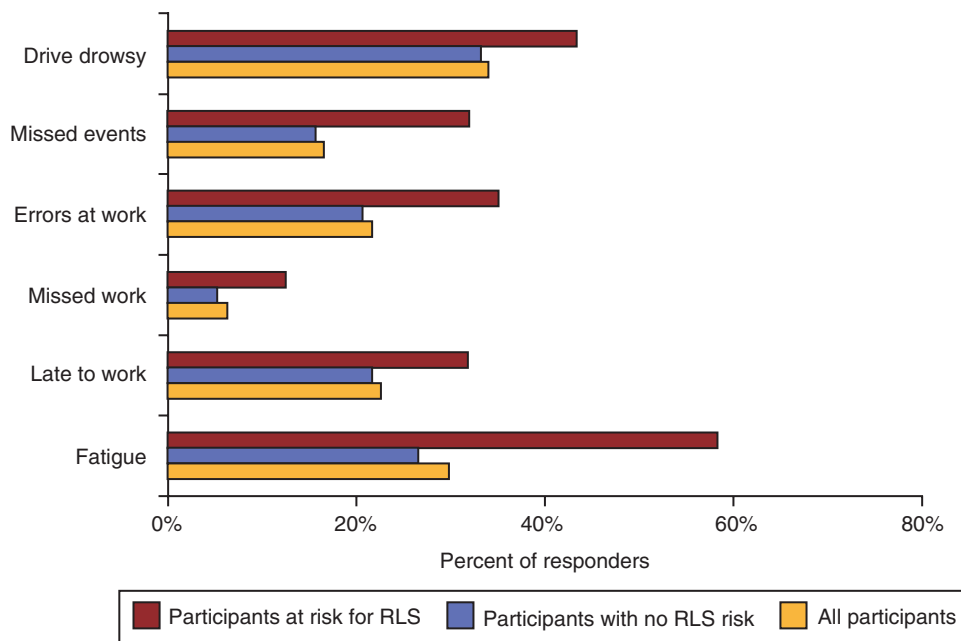

Parkinson's Disease

Sleep problems are common in all forms of Parkinson's disease (PD).⁸⁷ The most commonly seen neurodegenerative disorder in a sleep disorders clinic is Parkinson's disease.¹²

FIGURE 13-10 Comorbid conditions associated with late-onset (>45 years old), secondary RLS; OTs treat many of these patients in practice. Mg = magnesium, COPD = chronic obstructive pulmonary disease.

$p < 0.05$, at risk of RLS vs. not at risk of RLS

FIGURE 13-11 As the figure shows, RLS can have a significant impact on functioning in some daily occupations.

(From Avidon A: Restless legs syndrome and periodic limb movements in sleep. In Kryger MH, editor: *Atlas of clinical sleep medicine*, Philadelphia, 2010, Saunders Elsevier, p. 118.)

Of the patients with PD, from 60% to 90% have sleep complaints. A majority of clients with PD have sleep complaints that adversely affect sleep including excessive sleepiness, insomnia, nightmares, and other sleep disorders. As severity of the disease increases, sleep complaints also increase. Improved sleep hygiene is an important treatment that can be provided to this population in addition to training in safe bed mobility and transfer training and provision of adaptive equipment (e.g., bedside commode) for safety in toileting tasks.¹²

Consequences of Poor Sleep

Sleepiness

The seemingly obvious but not so obvious consequence of sleep debt is sleepiness. Behavioral signs of sleepiness include yawning, ptosis (drooping of the upper eyelid), reduced activity, lapses in attention, and head nodding.⁸¹ Besides the embarrassment that may be caused by those behaviors when in a public place, there are serious consequences to sleepiness.

The terms *sleepiness*, *fatigue*, and *somnolence* are sometimes used interchangeably. However, sleepiness should be distinguished from fatigue. Sleepiness is a sleep state that is characterized by the tendency to fall asleep, whereas fatigue is the exhaustion that occurs after exertion.⁴⁰ Another definition of fatigue, as cited by Bushnik, Englander, and Katznelson,¹⁹ is “the awareness of a decreased capacity for physical and/or mental activity due to an imbalance in the availability, utilization and/or restoration of resources

needed to perform activity” (p. 46).¹ Though many people, including sleep experts, use the word *somnolence* and *sleepiness* interchangeably, Gooneratne et al. believe that the terms should not be considered the same.⁴⁰ Somnolence is an impaired neurologic state that can lead to lethargy or coma, whereas sleepiness is a tendency to fall asleep.

As cited by Roehr et al.,⁸¹ sleepiness is a physiologic need state much like hunger or thirst. The body’s desire to sleep cannot be met by resting, eating, taking a cold shower, or exercising. It can only be met by sleep. Researchers have quantified sleepiness by how readily subjects fall asleep, by subjects rating how likely they are to fall asleep in certain situations, and by subjects rating themselves on how they feel at the moment. The Multiple Sleep Latency Test (MSLT) is considered the standard method for quantifying sleepiness.⁸¹ With this test, subjects are placed in a dark room on a bed. The amount of time it takes the subject to fall asleep is measured every 2 hours during the waking hours on several occasions. Severely sleep deprived individuals fall asleep instantly (zero sleep latency). Generally, many clinicians consider an average latency of 5 to 8 minutes to be consistent with excessive daytime sleepiness; 10 to 12 minutes or more is considered to be within normal limits.²⁴

Research has shown that those who are the most sleep deprived as evidenced by behavioral measures are the least accurate in rating their sleepiness. Roehr et al. have speculated that adaptation to the chronic sleepiness state occurs such that some people actually forget what complete alertness feels like.⁸¹ The researchers also reported that for those

with mild to moderate sleepiness, subjective complaints of sleepiness and even its behavioral indicators can be masked by a number of factors such as motivation, environment, posture, activity, light, and food intake. The researchers reported: “Heavy meals, warm rooms, boring lectures, and the monotony of long-distance automobile driving unmask physiologic sleepiness when it is present, but they do not cause it” (p. 41). However, for those with significant and severe sleep debt, the ability to override sleepiness diminishes. Even in the most exciting environment, microsleeps can occur as well as likelihood of sleep onset. An example would be a person falling asleep while watching an adventure movie during the most climactic scenes.

A healthy individual becoming sleepy while watching a movie is a relatively benign problem if it is isolated. However, research has found that sleepiness can be a detriment to functioning. One study found that excessive sleepiness in the elderly without dementia or depression was associated with self-reports of moderate impairments in activities such as housework, sports, activities in the morning or evening, and keeping pace with others.⁴⁰ In this study there were strong associations between those with a number of medical conditions and those reporting excessive sleepiness.

Other studies have shown a relationship that activities and positioning may have an effect on sleepiness. One study showed that sleep latency (how long one takes to fall asleep) increased by 6 minutes when the subject was sitting up rather than lying down. Sleep latency has been shown to also increase by 6 minutes when subjects went for a 5-minute walk prior to taking the MSLT.^{15,16}

Many well-known disasters can be attributed to workers who were sleep deprived, including the Exxon *Valdez* oil spill (1989), the Three-Mile Island nuclear meltdown (1979), and the *Challenger* space shuttle explosion (1986).^{26,29,97}

All these findings can have implications for occupational therapists who work with sleepy clients in their goal setting and treatment plans. For Mrs. Tanaka, if medical or psychiatric conditions or medication problems are ruled out, occupational therapists can help ensure the client gets adequate sleep at night. If Mrs. Tanaka’s sleep problem includes a shifted circadian rhythm, light exposure during treatment and between therapies during the day may help to shift her circadian pattern so that she sleeps at night, not during the day. Treatment in an upright posture in a bright room may help to keep her alert longer during treatment so that she can participate in therapy during the day.

Drowsy Driving

Researchers at the U.S. National Highway Traffic Safety Administration (NHTSA) looked at data during the periods of 1991-2007 on fatal single-vehicle run-off-road crashes. The most influential factor in the occurrence of these fatal crashes was sleepiness. The NHTSA reported that the odds of a sleepy driver being involved in a run-off-road crash are more than three times more likely than they are for a driver who is not sleepy.⁷¹ Compared to that, the odds of a driver

with alcohol in his system (blood alcohol concentration = 0.01 + grams per deciliter) is almost two times as likely to be in a similar crash than a sober driver. Currently, only the state of New Jersey enacted a Law (Maggie’s Law in 2003) that considers falling asleep at the wheel and fatigued driving a criminal offense in a fatal crash if someone is found to not have slept in 24 consecutive hours.

The National Sleep Foundation has reported the following as the groups most at-risk of being involved in a fall-asleep crash:⁷⁰

- Young people, especially males under 26
- Shift workers and people with long work hours
- Commercial drivers, especially long-haul drivers
- People with undiagnosed or untreated disorders (those with untreated OSA have been shown to have up to seven times increased risk of falling asleep at the wheel)
- Business travelers who drive many hours or are jet-lagged

Shift Work

Research that shift work can be deleterious to your health is well documented. As previously mentioned, the invention of artificial light and the Industrial Revolution changed the work world so that people can now work around the clock. The prevalence of shift work sleep disorder that results in insomnia is estimated to be about 10% of the night and rotating shift worker population.⁸⁰

Neuromuscular Disorders and Sleep

Individuals with neuromuscular disorders are considered in a “state of vulnerability” during sleep, as normal REM-related changes such as atonia and other changes in ventilation are magnified as a result of muscle weakness. Sleep disturbance can also be related to spasticity, poor secretion clearance, sphincter dysfunction, inability to turn, pain, and any associated or secondary autonomic dysfunction. All these factors can impair sleep and decrease daytime functioning.³⁹ Individuals who rely on accessory muscles to breathe (e.g., tetraplegia) are also in a vulnerable state during sleep. Sleep disturbance is also a common consequence of traumatic brain injury (TBI), and those with this condition constitute another population of clients that occupational therapists treat.⁷⁴

Other Consequences of Sleep Deprivation

As cited in Young et al.,⁹⁵ sleep deprivation can result in a multitude of negative physical and psychological consequences even when the person is healthy. These negative consequences include but are not limited to hypertension,^{37,75} decreased postural control,³⁴ and possible obesity and diabetes.^{38,57} Inadequate sleep can also result in greater likelihood of falls.⁸⁴ In older adults, the consequences of poor sleep are significant and can result in overall poorer health, physical function, cognitive function, and increased mortality.⁹

Sleep Considerations in the Hospital Setting

As mentioned previously, inadequate sleep can have serious consequences in and of itself. Acute hospitalization combined with inadequate sleep can further hinder recovery. Studies have shown that approximately half of patients admitted to general medical wards complain of sleep disruption. Young et al. have suggested that patients who are hospitalized have difficulty initiating and maintaining sleep and complain of early awakening and nonrestorative sleep.⁹⁵ Hardin reported that for more than 30 years sleep abnormalities have been documented in patients who are hospitalized in the intensive care unit (ICU).⁴⁵ Environmental noises and patient care activities account for about 30% of awakenings in ICU patients.³⁶ The noise levels in ICUs are found to be especially high.⁶⁵ However, nursing care activities such as taking vital signs and giving sponge baths may actually contribute more to the patient awakening than do the environmental conditions.³⁵

The etiology of sleep disturbances in the hospital or institutional setting are multifactorial and can be related to a patient's medical illness, medical treatments, and environment.⁹⁵ Patients treated in a traditional rehabilitation setting may also have a higher likelihood of sleep disturbance. One study indicated that of 31 consecutive admissions to a brain injury unit with a diagnosis of closed head injury (CHI), 68% were shown to have sleep-wake cycle disturbance.⁵⁹ Those with the aberrations in nighttime sleep had longer stays in both the acute and rehabilitation settings, important to consider with concerns over high healthcare costs.

Taking account of these factors, it is important to consider Mrs. Tanaka's sleep patterns at the facility or unit prior to admission to the rehabilitation hospital or unit. Was Mrs. Tanaka in the ICU? How long was she there prior to admission to the rehabilitation unit? Was her sleep disturbed in that setting?

To Nap or Not to Nap?

The research has been mixed on whether it's a good idea for one to nap during the day. The primary concerns are that napping fragments sleep and that consolidated nighttime sleep may be disrupted as a result. One study suggested that sleep disruption is common and severe among older persons receiving inpatient postacute rehabilitation and that excessive daytime napping was associated with less functional recovery for up to 3 months after admission.² However, other researchers are finding benefits to napping and recommend short naps as we age to accommodate the normal age-related changes to sleep (Box 13-4).⁴⁶

Nocturia

Nocturia is defined as waking one or more times to void (urinate) at night and is the most common lower urinary tract symptom.¹⁷ As Booth and McMillan have cited,¹⁷ prevalence studies indicate that nocturia increases in both genders with age.^{50,82} The most significant consequence of nocturia is sleep disturbance with evidence of fatigue during

Box 13-4

How to Take a Good Nap

- Keep the nap short. Even a few minutes may have benefits. A 20- to 30-minute nap may be ideal. A longer nap may lead to postsleep grogginess ("sleep inertia").
- Find a dark, quiet, cool place with reduced noise.
- Plan a nap in the afternoon instead of napping haphazardly.
- Time caffeine intake to not coincide with the nap.
- Don't feel guilty about the nap. A good, well-timed nap can actually help to increase productivity.

(Harvard Health Letter, 2009.)

the day impacting energy and activity.¹⁰ Research shows that there is an association between risk of falls and nocturia and that caregivers and other sleeping partners are also at risk of falls during the night and day because of fatigue due to sleep disruption.¹⁰ When evaluating clients on their ADL status, occupational therapists should always ask clients about their voiding habits at night. Frequency of voiding can alert the occupational therapy practitioner to sleep disturbances and help to determine safe toileting equipment, routines, splint schedules, safe environmental setup, and need for referral to the client's physician.

Occupational Therapy and Sleep

In current practice, a sleep disturbance may not be the primary reason a client is seeking services from occupational therapy. However, because it is established that insufficient sleep can negatively impair all occupations, it is clearly an important area to consider in occupational therapy treatment in all practice settings. Based on estimates from a 2006 survey from state occupational therapy regulatory boards, AOTA staff estimate that there are roughly 118,500 occupational therapy practitioners in the workforce in the United States.⁶ Occupational therapy practitioners in all practice settings being well versed on the topic of sleep and rest can have a significant positive impact on society.

Occupational Therapy Evaluation

It is important to obtain a thorough occupational profile of the client during the evaluation. This includes the client's history and experiences, patterns, interests, values, and needs.⁷ Included in the profile should be questions regarding the client's sleep and rest patterns, routines, and habits. A thorough medical history and information on whether the client has a history of sleep disorders or difficulties should be included.

Occupational Therapy Intervention for Sleep and Rest

According to the OTPF-2,⁷ the types of occupational therapy intervention include therapeutic use of self, therapeutic use of occupations and activities, consultation,

education, and advocacy. All of these interventions can be used when treating patients regarding the occupations of sleep and rest.

Therapeutic Use of Self

The occupational therapy practitioner can demonstrate caring and concern for the client or caregivers regarding the amount and quality of rest and sleep they are obtaining. Sleep medicine is a relatively new discipline, so many doctors do not ask their patients about their sleep or don't recognize the signs of sleep disorders or issues.³³ The occupational therapy practitioner may be the first to ask a client/caregiver of sleep concerns because of occupational therapy's attention to occupations, routines, and life balance.

The occupational therapy practitioner can practice "mindful empathy," which is an objective mode of observation of the client's emotions, needs, and motives while being objective.⁸⁵ Instead of judging a client for canceling appointments or not fully participating in treatment, actively listening to a client and reassessment of the situation could reveal a sleep-deprived client.

Therapeutic use of self also includes occupational therapy practitioners being more knowledgeable and having competency in the areas of sleep and rest to help clients to optimize their sleep and rest patterns. Becoming knowledgeable about sleep and sleep disorders can help the occupational therapy practitioner to recognize any problems that may indicate severe sleep disturbance so the client can be referred to a doctor or sleep specialist.

Occupational therapy practitioners can also model good sleep practices so they are alert, safe, and functioning at their best when working with clients. Occupational therapy practitioners need to examine their own values about sleep and rest. Is sleep and rest considered a waste of time? Is someone lazy if they require a nap during the afternoon?

Developing cultural competency is a "central skill" for using oneself therapeutically.⁸⁹ As previously mentioned, recognizing and appreciating diversity in sleep and rest is important as definitions, patterns, practices, and environments may completely differ from our own. Mrs. Tanaka's views and experiences with sleep, habits, and patterns of sleep are all important considerations when treating her. For example, if Mrs. Tanaka's family reports she always used a night light to sleep and was afraid of the dark, we should not impose complete darkness in her room at night as a sleep hygiene technique.

Therapeutic Use of Occupations and Activities

The therapeutic occupations and activities can focus on helping the client to have a healthy lifestyle balance and routines to ensure adequate rest and sleep. An activity configuration or pie chart can be used with the client to review occupations that are important to the client and to assess how time is spent and the portion of time allocated to each of these occupations.

Activities of Daily Living

Schedules

Consider optimal times for activities of daily living (ADLs) training (e.g., if client is a "night owl," don't schedule shower/dressing training at 7 a.m.). Try to schedule certain ADLs at "customary" times, especially for clients with cognitive impairment (e.g., working on dressing in the a.m. instead of at 1:30 in the afternoon) so that they become accustomed to a routine. Consult with other team members or family members and ensure that clients are getting sleep and rest. Keep track of sleep by using a sleep chart or diary. Schedule in regular daytime naps in bed (if possible; not in a wheelchair or recliner) or rest breaks if needed. Keep the medical team informed about client's alertness during therapies.

Dressing

If dressing is considered a usual habit for a client, dissuade the use of pajamas during the day and have clients dress in "street" clothes during the day. Encourage pajamas or "usual" sleeping clothes at night while on a rehabilitation unit or when recovering from illness or injury at home. However, it is important to note that some clients regularly wear housecoats during the day. Some cultures may also deem it necessary to wear pajamas because the client is still considered "sick."

Hygiene and Grooming

If a client normally shaves or wears makeup during the day, encourage this as part of the morning/daytime routine if it's important to the client. Ensure that the client and caregiver have a routine for activities to get ready for the day and to go to sleep at night.

Bed Positioning/Bed Mobility/Bed/Bedding

Train the client and caregiver(s) in bed positioning to ensure comfort and optimal functioning. Are there enough pillows? Does the head of bed need to be elevated? Does an extremity need to be elevated? Are there other precautions that need to be followed while the client is in bed (total hip, logroll, etc.)? Train the client and caregivers in bed mobility techniques for safety. Assist in determining the optimal bed for the client to use to facilitate sleep with consideration for skin protection, breathing, and mobility/transfer status at the forefront. Ensure that the client has easy access to call light, and make or request adaptations to the call light if needed. If the client is going to be away from home, consider if a special quilt or blanket from home may assist the client to sleep or whether particular textures for sheets may be more suitable for the client to use during sleep for skin protection or comfort.

Environment

To encourage sleep, turn lights off, encourage a quiet room, turn the TV off, and close the door fully if needed and if safe. Consider whether client gets overstimulated with too

many items posted on the wall. Make sure the floor is clear of clutter and obstructions for safety. Remove throw rugs. Make sure the temperature in the room is comfortable for the client to sleep. Extra blankets may be needed for those clients who tend to get cold.

Transfers

Train client, caregivers, and family members in safe transfer techniques onto commode or other transfers that may occur at night.

Toileting

Consider the most appropriate times for catheterization, voiding, and bowel program to optimize rest and sleep. Ensure that any equipment (commode, urinal, etc.) is readily available by the bedside. Discuss with medical team, client, and caregivers optimal toileting techniques to encourage sleep at night for all concerned and for safety (e.g., with approval by the physician, for males, initial use of condom catheter at night for urination versus use of commode if transfers are difficult).

Showering/Bathing

Consider the most optimal time for a bath or shower to encourage sleep at night or wakefulness during the day to participate in therapies or daytime activities. Perhaps a morning shower would “wake up” a client in the morning. Consider that optimal times for client to take shower or to bathe may be at night to help with sleep. Safety should be the highest consideration when determining showering/bathing times.

Eating/Meals

Work on feeding activities and encourage meals out of bed with the rest of the family in the family dining area, as appropriate, to ensure that daily rhythms are reinstated to help distinguish day from night.

Home Safety Evaluation

As appropriate, perform a home evaluation to ensure that the home is safe for transfers, toileting, ambulation at night, and to determine any equipment needs. Suggestions can be made for bed placement, and night lights and call bells can be set up as needed. Confer with a physical therapist about optimal ambulation devices.

Other Activities

Try to schedule treatments outdoors so that the client is exposed to light as it is the strongest zeitgeber and can help to reset the biological clock if it is off kilter. Collaborate with the client and family to make sure activities selected are interesting and important for the client. Clients sometimes sleep during the day because they're bored. Encourage participation in activity groups, therapeutic recreation groups, and community events if it helps the client to sleep at night. Make suggestions for and encourage quiet restful

evening activities. As mentioned previously, Howell and Pierce have pointed out that occupations that are highly restorative tend to have strong routines of simple and repetitive nature, are often considered pleasurable, and have personal meaning to the individual.⁴⁹ West has suggested relaxing activities such as reading, stretching, meditating, or praying before bedtime.⁹¹ Use of sleep preparatory activities such as visual imagery and massage can also be used.⁹¹ Some evidence suggests that aromatherapy with essential oils such as lavender and chamomile may have some promise in helping to induce a state of mind that assists with sleep.⁹² However, continued research is needed to find evidence of its effects on sleep architecture by polysomnography.⁹²

Community Mobility

Occupational therapy practitioners can train clients who are no longer deemed safe to drive because of sleep disorders in community mobility and alternative transit (see Chapter 11, Section III).

Splint/Exercise Schedule/Pain

Consider client sleep when giving splinting schedule instructions. Ensure proper fit for comfort so that client can sleep. Make sure the splint schedule doesn't interfere with sleep or that the continuous passive motion (CPM) machine, typically used with clients who require a total knee replacement, doesn't keep the client awake all night. Collaborate with physical therapy about CPM use. Make sure exercises are performed at a time that will optimize sleep at night. Consider client pain levels and consult with medical staff and doctors. Talk to the client about whether he or she is unable to sleep at night because of pain.

Cognitive Strategies

Develop cognitive strategies to help manage negative, anxiety-producing thoughts and concerns.⁵⁶ Examples of negative, anxiety-producing thoughts are “I'll never sleep again” or “It's already 2 o'clock in the morning, and I have to wake up in four hours.” Occupational therapists can consider training in cognitive behavior therapy (CBT). Cognitive behavioral therapy usually focuses on modifying unhealthy sleep habits, decreasing autonomic and cognitive arousals, altering dysfunctional beliefs and attitudes about sleep, and educating clients about healthier sleep hygiene practices. Research has supported the use of CBT as a non-pharmacologic treatment to sleep disturbance.⁵¹

Consultation

Occupational therapists can provide consultation in institutional settings where a 24-hour “on” schedule is frequently in place. Consult with the treatment team and staff about providing an optimal sleep environment for clients at night. Discuss with team the necessity for middle-of-the-night nonurgent blood pressure readings, sponge baths, and blood draws, and recommend they be avoided. Provide training to night-shift aides, nurses, orderlies, and caregivers in bed

mobility, bed positioning, transfer techniques, and body mechanics.

The occupational therapist can act as a consultant in worksite settings and can meet with managers and administrators about the importance of sleep for optimal functioning and safety. Encourage balance in life for a more productive and safe workforce. West pointed out that consultation services may be particularly useful in settings that employ shift workers (e.g., hospitals, factories, airlines), providers of driver education, the military, and emergency relief programs.⁹¹

Certified rehab driving specialists who are occupational therapists can educate clients and the public at large about the dangers of drowsy driving (see Chapter 11, Section III). These occupational therapists who are specialists in adaptive driving and evaluation for disabled or at-risk individuals are usually the most up to date about regulations and information regarding driving, and they can act as consultants to other occupational therapy practitioners and healthcare professionals.

Education

In an institutional setting, the occupational therapist can educate and empower the client and family to have a strict visitation schedule if needed and dissuade “too many” visitors at night or during scheduled rest times, which may interrupt rest and sleep when one is in an acute hospital setting. Occupational therapy practitioners can help empower caregivers to limit visits to short periods of time or help with the enforcement of visitation rules. The occupational therapist can educate caregivers about sleep and make sure they realize how important it is for them to get their own rest and sleep.

Some institutions require doors in rooms to be open at night despite the lights and noise. Education can be provided to staff about how best to facilitate sleep in these settings. Young et al. suggested several strategies,⁹⁶ including offering earplugs and eye masks, encouraging regular nocturnal sleep time, and discouraging long daytime naps. Other suggestions include encouraging the medical staff to minimize nighttime bathing, dressing changes of wounds, or other medical procedures and to avoid discussing emotionally charged topics with the patient at night.

Occupational therapy school educators can inform their college students—who are known to be at risk for erratic sleep behaviors and significant sleep debt—about the consequences of sleep deprivation. If afternoon classes are scheduled, more “active” class activities may be required to fend off sleepiness for the instructors and students during the circadian clock’s “sleepiness” times. Occupational therapy and occupational science educators can coordinate assignment due dates and spread them out to encourage balance for the instructor and students and to ensure proper sleep for both.

As cited by Green, Hicks, and Wilson,⁴² patients complain of the lack of information about the management of insomnia.⁷² Occupational therapists can provide education to the sleep-deprived public in community practice settings.

Sleep Hygiene

Sleep hygiene refers to activities involving lifestyle choices and environmental factors that can lead to healthy sleep. Sleep specialists provide sleep hygiene education with the intent to provide information about lifestyle and environments that either interfere or promote sleep.⁶⁸ Occupational therapy practitioners can also provide sleep hygiene information to support healthy active engagement in other areas of occupation.⁷

In its description of sleep as an occupation, the OTPF-2 describes sleep hygiene activities thusly: “A series of activities resulting in going to sleep, staying asleep, and ensuring health and safety through participation in sleep involving engagement with the physical and social environments” (p. 632)⁷ (Box 13-5).

Recommendations for Sleep Hygiene

- Develop a regular sleep-wake cycle. Use an alarm clock if needed.
- Develop a relaxing routine before bedtime.

Box 13-5

Sleep Hygiene Areas for Consideration According to OTPF-2

Preparation of Self

- Developing routines that prepare one for comfortable sleep such as grooming, undressing/dressing, reading, listening to music to fall asleep, saying goodnight to others, meditation or prayers
- Determining the time of day and length of time desired for sleeping or time needed to wake
- Establishing patterns that support growth and health (patterns are personally and culturally determined)

Preparation of Environment

- Making the bed or space on which to sleep
- Ensuring warmth/coolness and protection
- Setting an alarm clock
- Securing the home, such as locking doors or closing windows or curtains
- Turning off electronics or light

Participation in Actual Sleep

- Ceasing of activities to ensure onset of sleep, napping, and dreaming
- Ceasing of activities to sustain a sleep state without interruption
- Nighttime care of toileting needs or hydration
- Negotiating needs of others in the social environment
- Interacting with those who share the sleeping space (e.g., children or parents)
- Nighttime caregiving, such as breastfeeding
- Participating in activities to ensure, monitoring the comfort and safety of others, such as the family, while sleeping

Data from American Occupational Therapy Association: Occupational therapy practice framework: domain and process, second edition, *Am J Occup Ther* 62(6), 2008.

- Prepare a quiet environment for sleep or use “white noise” to foster sleep.
- Avoid mentally stimulating or arousing activities before bedtime.⁵⁶
- Remember that the only activities that should occur in bed are sleep and sex (avoid reading, watching TV, texting, tweeting, or using other media/computer devices in bed).
- Keep a sleep diary.
- Do not use alcohol to fall asleep. Alcohol can make snoring and OSA worse. Evidence exists that three to five glasses of alcohol in the evening can cause arousal when the effects of the alcohol wear off.²⁹
- Do not use caffeine prior to sleep. Caffeine has a half-life of 3.5 to 5 hours depending on one’s age, activity, or body chemistry, which means that it could be in your body for many hours after ingesting it.^{29,63}
- Limit liquids at night.
- Avoid medicines that will keep one awake at night. Confer with a doctor about medications taken at night, particularly those affecting sleep occupations (no diuretics at night, etc.).⁹⁵
- If one can’t fall asleep in a reasonable amount of time (e.g., 15 minutes) while in bed, leave the bed, go to another room, or perform another activity until one feels sleepy.

Determining When to Refer to a Physician/ Sleep Specialist

Refer the client to a physician or sleep specialist if he or she complains of any of the following conditions:³³

- Has trouble initiating sleep or getting restful sleep for more than a month or two
- Does not feel rested despite getting the usual amount of sleep or more sleep than he or she is accustomed to getting in order to feel rested
- Falls asleep at inappropriate times, even though he or she is getting 7½ to 8 hours of sleep
- Is told he or she snores loudly or gasps and has periods of not breathing that disrupts a bed partner or roommate
- Has to sleep in a different room because a bed partner claims the client’s snoring is too disruptive
- Follows good sleep hygiene habits but still has difficulty sleeping

Other reasons to refer a client to a physician or sleep specialist:

- Caregivers complain that the client is awake all night and sleeps all day.
- A cognitively impaired client is not able to report clearly his or her sleep habits but has obviously declined in occupational performance areas

Epworth Sleepiness Scale

Using the following scale, circle the *most appropriate number* for each situation.

0 = Would doze *less than once a month*
 1 = *Slight* chance of dozing
 2 = *Moderate* chance of dozing
 3 = *High* chance of dozing

Situation	Chance of Dozing			
Sitting and reading	0	1	2	3
Watching TV	0	1	2	3
Sitting, inactive in a public place (in a theater or in a meeting)	0	1	2	3
As a passenger in a car for an hour without a break	0	1	2	3
Lying down to rest in the afternoon (when circumstances permit)	0	1	2	3
Sitting and talking to someone	0	1	2	3
Sitting quietly after a lunch without alcohol	0	1	2	3
In a car, while stopped for a few minutes in the traffic	0	1	2	3

Add the 8 numbers you have circled **Total _____**

FIGURE 13-12 The Epworth Sleepiness Scale was validated in clinical settings and can be used by occupational therapists to collect information to refer a client to a physician. A total of 10 or more indicates excessive daytime sleepiness. A score of 6 is the norm. However, clients with insomnia can have scores in the normal range. A score of 12 to 24 may indicate a severe abnormality.

(Adapted from Johns MW: A new method for measuring daytime sleepiness: The Epworth Sleepiness Scale, *Sleep* 14(6):540-545. Zupancic M, Swanson L, Arnedt T, and Chevrin R. Impact, presentation and diagnosis. In MH Kryger, editor: *Atlas of clinical sleep medicine*, Philadelphia, 2010, Saunders.)

(ADLs, mobility, etc.) and you suspect poor sleep.

- The client falls asleep regularly during your treatment in the daytime.

If appropriate, have the client fill out a sleepiness scale such as the Epworth Sleepiness Scale, which was validated in clinical settings (Figure 13-12).⁵³ A total of 10 or more indicates excessive daytime sleepiness. A score of 6 is the norm.⁹⁷ Present the data to the client's doctor. Notify the physician of the client's deficits in occupational performance or other symptoms resulting from sleep deprivation.

Summary

Historically, occupational therapists and occupational scientists have been interested in the importance of helping clients to maintain a healthy balanced lifestyle.²⁵ Included in that balance should be adequate sleep and rest, two “restorative” occupations.⁷⁸ According to the second edition of the Occupational Therapy Practice Framework,⁷ the category of sleep and rest is considered a major occupational performance area that is in the domain of occupational therapy practice; accordingly, addressing this area in all practice settings is appropriate.

Occupational therapists have not traditionally treated clients whose diagnosis or problem has been primarily sleep disorders. However, the sleep medicine literature abounds with information about the deleterious effects of sleep deprivation, including the effects on the at-risk clients whom occupational therapists treat on a daily basis in physical disability and other practice settings. Although occupational therapy has not focused research on rest and sleep, sleep medicine research affirms what occupational therapy practitioners have known all along. Humans need to sleep. Humans need to rest. Otherwise, occupational performance declines and can negatively affect one's quality of life and health. However, compelling evidence suggests that occupational therapists could and should put more emphasis, research, and practice in helping clients who have sleep difficulties.

Reflecting on the case of Mrs. Tanaka, it is evident that occupational therapy practitioners can help make a positive difference in her rehabilitation outcomes by focusing on her sleep disturbance once medical issues have been ruled out. A multitude of reasons may explain Mrs. Tanaka's sleep disturbance. The exact location of her brain injury event may help the medical team determine if the disturbance is organic. The occupational therapist who is educated and attuned to the sleep and rest needs of Mrs. Tanaka can—through the therapeutic use of self; the therapeutic use of occupations; and activities, consultation, education, and advocacy—help the client to successfully reach her rehabilitation goals.

Review Questions

1. What is sleep architecture?
2. Does sleep architecture change as we age?
3. What is REM sleep, and how does it differ from NREM sleep?
4. Why should occupational therapy practitioners address sleep in their practice?
5. What is the difference between sleep and rest?
6. Where does the area of sleep and rest fit into the second edition of the Occupational Therapy Practice Framework?
7. What is sleep hygiene?
8. What is the Multiple Sleep Latency Test? What is the Epworth Sleepiness scale?
9. When is it appropriate to refer a client to a physician or sleep specialist?
10. How can an occupational therapist help to improve a client's sleep hygiene in a hospital setting?
11. Name at least five consequences of inadequate sleep.
12. What is obstructive sleep apnea, and what are some signs and symptoms of the disorder?

■ Chapter Outline

History of occupational therapy involvement in work programs

Role of the occupational therapist in work programs

Industrial rehabilitation

Functional capacity evaluation

Vocational evaluations

Job demands analysis

Work hardening/work conditioning

Worksite evaluations

Ergonomics

Workstations

Seating

Visualizing the job task

Tools

Materials handling

Ergonomic evaluation

Injury prevention programs

Empowering corporate clients: the injury prevention team

Management commitment

Training in risk factor identification/ergonomic evaluation and problem solving

Developing risk factor controls

Medical management strategies

Outcomes assessment and preventing future problems

Pre-employment testing

Transition services from school to work

Transition-related evaluation

Service planning

Program implementation

Work readiness programs

Community-based services

Community rehabilitation programs

Homeless shelter programs

Welfare-to-work programs

Ticket to work

Future trends

Summary

Review questions

■ Key Terms

Vocational evaluation

Industrial rehabilitation

Functional capacity evaluation

General vocational evaluation

Specific vocational evaluation

Job demands analysis

Essential tasks

Work hardening

Work conditioning

Worksite evaluations

Ergonomics

System theory

Ergonomic evaluation

Primary prevention

Secondary prevention

Tertiary prevention

Work-related musculoskeletal disorders

Work readiness program

■ **Learning Objectives** *After studying this chapter, the student or practitioner will be able to do the following:*

1. Understand the role of occupational therapy in the development of work programs.
2. Describe the different types of work evaluation and work programs that are currently being practiced.
3. Identify the components of an industrial rehabilitation program.
4. Understand the difference between work hardening and work conditioning.
5. Identify the aspects of a well-designed functional capacity evaluation.
6. Explain the importance of reliability and validity in the context of evaluation.
7. Understand the differences between job demands analysis, ergonomic evaluation/hazard identification, and worksite evaluation.
8. Discuss the application of job demands analysis.
9. Discuss basic ergonomic interventions.
10. Describe the components of injury prevention programs.
11. Describe school-to-work transition services.
12. Describe the purpose of a work readiness program.
13. Identify various community-based work programs.

Threaded Case Study | Joe, Lorna, and Henry, Part 1

Joe is a 26-year-old man who worked two jobs to support himself and his daughter, who lived with his ex-wife. He worked as a janitor during the day at a hotel and spa and cleaned offices at night. Because of a motor vehicle accident, he sustained a T11 spinal cord injury, which resulted in complete paralysis of his legs. Since this injury affected his mobility, strength, and effort, he could not return to janitorial work because he would not be able to effectively carry out the essential functions of the job from a wheelchair. Fortunately, one of Joe's employers, the hotel and spa, liked him because he was a good worker and was willing to offer him an alternative job as a laundry attendant if he could meet the physical demands of the job. Joe was referred to occupational therapy by his physician.

Lorna is a 39-year-old single mother who has been working at the same job in a St. Louis upholstery factory for the past 20 years. Lorna's job is to pull heavy fabric tightly over a padded wooden frame and then staple the fabric to the frame. Once she is finished stapling, she pushes the piece of furniture over to a coworker, who checks her work and then wraps the piece of furniture in thick plastic. It is hard work and her hands and back often ache at the end of the day from pulling the fabric tightly, using the heavy staple gun, and handling the awkward furniture. With the holidays approaching, Lorna and coworkers decide to put in extra hours to make some additional money to buy presents for their children. Lorna is now experiencing significant pain, numbness, and tingling in her hands. She can no longer just shake her hands out to make it go away. She is having trouble holding onto the fabric and often drops the staple gun. She has had to take a few days off work because of the pain in her back and hands.

Henry is a 42-year-old father and husband who has been supporting his family by working as a roofer for the past 15 years. On one of his work assignments he fell off the roof and sustained a traumatic brain injury and a couple of lower extremity fractures. As a result, his motor and praxis skills, sensory-perceptual skills, cognitive skills, emotional regulation skills, and communication and social skills have been affected.

He has been receiving worker's compensation for 2 years; Henry now feels ready to return to some type of work but does not know what he can do. He has enough insight to know that he cannot return to roofing but would like to do something with his life.

Critical Thinking Questions

As you read through the following information on occupational therapy work evaluation and intervention, keep in mind the circumstances of Joe, Lorna, and Henry to determine which services they may benefit from most.

1. What type of evaluation and services could occupational therapy offer to assist Jose, his physician, and the employer?
2. What occupational therapy interventions can help Lorna and her work environment?
3. What work-related occupational therapy services can help Henry discover what type of work that he can do at this point?

One of the most significant occupations in which adults engage is work. A stable job provides the means to acquire the most basic physiologic and safety requirements that humans need to survive and thrive: food and water, a safe place to sleep, and the security of knowing that these resources will continue to be available. For many, belonging and esteem needs are also met at the workplace. Anything that prevents an adult from participating in the occupation of work will have significant consequences for that individual's health and well-being. According to the Office of Disability Employment Policy of the U.S. Department of Labor, in August, 2010, 22% of the labor force consisted of people with disabilities. The unemployment rate for those with disabilities was 15.6%. Occupational therapy practitioners play a key role in helping workers maintain their employment despite the symptoms that they experience, as well as facilitating one's entry or re-entry into the workforce.

History of Occupational Therapy Involvement in Work Programs

The therapeutic use of work has always been a core tenet of occupational therapy since the inception of the profession.³² Work programs have their roots in those with mental illness during the moral treatment movement, which started in Europe in the late 18th and early 19th centuries.⁷⁷ In 1801, Philippe Pinel, one of the founders of moral treatment, first introduced work treatment in the Bicentre Asylum for the Insane. He suggested that “prescribed physical exercises and manual occupations should be employed in all mental hospitals. ... Rigorously executed manual labor is the best method of securing good morale. ... The return of convalescent patients to their previous interests, to industriousness and perseverance have always been for me the best omen of a final recovery.”⁸⁰ Later in the 1800s, several psychiatric settings instituted productive activity programs.

In 1914, George Barton, one of the founding fathers of the occupational therapy profession who was disabled by tuberculosis and a foot amputation, established the Consolation House in New York.⁸⁹ This program enabled convalescents to use occupations to return to productive living.⁸⁹ Barton stated, “the purpose of work was to divert the mind, exercise the body, and relieve the monotony and boredom of illness.”⁸³

In 1915, Eleanor Clarke Slagle, another founder of the occupational therapy profession, was hired to create a program for persons with mental or physical disabilities to work and become self-sufficient.⁸⁹ The program was located at Hull House, a settlement house in Chicago, and was funded by philanthropic contributions. The participants involved in the program produced goods such as baskets, needlework, toys, rugs, and cabinets while developing manual skills and receiving wages for their work.

The early leaders of occupational therapy identified the importance of work when defining the profession’s focus and purpose. Adolph Meyer, a psychiatrist who emigrated from Germany at the time and was an early proponent of moral treatment, observed that healthy living involved a “blending of work and pleasure.”⁶¹ Dr. Herbert Hall helped establish a medical workshop at Massachusetts General Hospital in Boston, where clients were involved in “work cure.”³⁰ In this workshop, clients produced marketable goods and received a share of the profits. The focus of treatment in these curative workshops was to restore the impaired body part to as normal function as possible, with the goal of returning the client to work.

While this curative workshop movement was transpiring on the East Coast, similar programs were developing elsewhere in the United States. For example, at the Los Angeles County Poor Farm, now recognized as Rancho Los Amigos National Rehabilitation Center in Downey, California, “all inmates were requested to do an amount of work that was commensurate with their physical strength and mental

FIGURE 14-1 A, Patients at work weaving rugs in the occupational therapy shop at the Los Angeles (LA) County Poor Farm. B, Patients with a display of their products made at the LA County Poor Farm.

(From Flidner CA: Occupational therapy: for the body and the mind. In Rodgers GM, editor: *Centennial Rancho Los Amigos Medical Center 1888-1988*, Downey, Calif, 1990, Rancho Los Amigos Medical Center.)

capacity, which was determined by the admitting doctor.”²⁷ Inmates used woodworking machinery to build a large amount of furniture that was used at the farm. Commodes, bedside tables, wheelchair tables, park benches, cabinets, and other items were built in the shops. In later years when there was a true occupational therapy department, patients made Navajo-type rugs, rag or braided rugs, brushes, shawls, pottery, pictures, baskets, and leatherwork (Figure 14-1, A). Patients took special occupational therapy classes “which were designed to enable those who are crippled, blinded or otherwise handicapped to make themselves useful” by producing articles that could be used at the County Farm or sold to employees or the California Crafts and Industries Society in Los Angeles (Figure 14-1, B).²⁷

In the early 1900s, the medical profession did not seem to consider vocational readiness programs to be important. The focus of care for persons with physical illnesses was primarily palliative and involved immobilization and bed

rest. This attitude shifted after World War I with the need to rehabilitate the large numbers of injured soldiers to help them become functional and gain employment.

The U.S. Federal Board for Vocational Education (FBVE) was created after adoption of the Vocational Education Act of 1917.⁴² In 1918, the Division of Orthopaedic Surgery in the Medical Department of the Army organized a reconstruction program for disabled soldiers.⁷⁷ One of the founders of occupational therapy, Thomas Kidner, served as an advisor. This program led to the development of reconstruction aides, who were the precursors to occupational and physical therapists. Treatment involved both handicrafts and vocational education. The reconstruction aides used work activities to return the injured soldiers to military duty or civilian life to the highest degree possible.

In 1920, Congress passed the Civilian Rehabilitation Act of 1920 (Smith-Fess Act, Public Law 66-236). This law provided funds for vocational guidance and training, work adjustment, prostheses, and placement services.⁴² If therapy was part of a medical treatment program, the law provided payment for occupational therapy services; however, it did not provide payment for physician services. Physicians either provided free services or received payment through state or volunteer contributions. This limited the use of occupational therapy services in vocational rehabilitation to the states that supplemented federal program funds to support services such as the curative workshops.

The Social Security Act of 1935 defined rehabilitation as “the rendering of a person disabled fit to engage in a remunerative occupation.”⁵³ This was the first attempt to provide vocational rehabilitation to the physically handicapped in the community.

In 1937, industrial therapy, called employment therapy, was born.⁵⁸ The occupational therapist used activities as treatment modalities. It was common for patients to have work assignments in the hospital that matched their experience, aptitude, and interest. Sheltered work environments within the hospital were used, including the hospital laundry, barber shop, and carpenter shop.

The term *prevocational* started appearing in the literature by the late 1930s. It referred to the use of crafts to develop skills readily transferable to industry.¹⁰¹ Prevocational therapy prepared patients for the work role. Occupational therapists worked as directors, work evaluators, and prevocational therapists in work programs. In the 1940s, prevocational programs and work evaluation were accepted as part of the practice of occupational therapy. Patients in acute care facilities who were physically disabled were transferred to outpatient or rehabilitation prevocational and vocational programs.

World War II brought more opportunities for occupational therapists to become involved in work programs. With the advancement of medicine and pharmacology, many injured soldiers survived their wounds. Federal funding for rehabilitating disabled veterans increased as the government discharged the disabled soldiers. This led to an

increase in the development of work programs designed to evaluate and rehabilitate injured veterans.¹⁷

In 1943, the Barden-LaFollette Act (Public Law 78-113) modified the original provisions of the Civilian Rehabilitation Act of 1920.⁴² This new law, called the Vocational Rehabilitation Act, covered many medical services, including occupational therapy and vocational guidance. Services were expanded to those with physical and mental limitations. This law also created the Office of Vocational Rehabilitation, a state and federally funded agency that is still in existence today and provides job training and placement services to people with disabilities. Industrial therapy continued in various settings as a form of vocational rehabilitation.

During the 1950s, many occupational therapists believed that work evaluation belonged to a newly established profession of vocational rehabilitation rather than occupational therapy.⁵⁸ Occupational therapy involvement declined, and vocational counselors, vocational evaluators, and work adjusters were primarily the leaders in this field. There were, however, still a few occupational therapists who remained active in work programming.

A high point in the development of prevocational exploration and training techniques in the field of occupational therapy occurred in 1960.⁴² Rosenberg and Wellerson published an article on development of the TOWER (Testing, Orientation, and Work Evaluation in Rehabilitation) system in New York.⁸⁴ The TOWER system was one of the first work sample programs to use real job samples in a simulated work environment.⁸⁴ In 1959, Lilian S. Wegg gave the Eleanor Clarke Slagle Lecture on “Essentials of Work Evaluation” based on her experiences at the May T. Morrison Center for Rehabilitation in San Francisco. Wegg promoted the need for both sound testing procedures and training programs.¹⁰⁰ Florence S. Cromwell, a president of the American Occupational Therapy Association (AOTA), established norms for disabled populations on certain prevocational tests while evaluating the performance of adults with cerebral palsy at the United Cerebral Palsy Organization.⁴² Cromwell continued to be an important advocate of work-related therapy in the ensuing decades.

Occupational behavior theory, which emerged in the mid-1960s and early 1970s, offered a return to the profession's concern for occupation. Mary Reilly, an early proponent of occupational behavior theory and a 1962 Eleanor Clarke Slagle lecturer, believed that productive activity as treatment was the unique contribution of occupational therapy.⁴² Occupational behavior theory advocated that persons can achieve healthy living only through a balance between work, rest, and play.

The increasing numbers of industries in the late 1970s and early 1980s introduced a whole new arena for occupational therapists: industrial rehabilitation and work hardening.⁴² Work hardening used actual work tasks in a simulated structured work environment, generally in community-based settings.⁵ Occupational therapists used

their knowledge of neuromuscular characteristics, including range of motion (ROM) and endurance, along with task analysis skills and knowledge of the psychosocial aspects of work in evaluating, planning, and implementing a work-hardening program.

In 1989, the Commission on Accreditation of Rehabilitation Facilities (CARF) developed work-hardening standards requiring an interdisciplinary approach.¹⁵ The interdisciplinary team consisted of occupational therapists, physical therapists, psychologists, and vocational specialists.

The Americans With Disabilities Act of 1990 (ADA; Public Law 101-336) was important legislation that opened major markets for occupational therapists.⁴² Occupational therapists were involved in providing both work training for persons with disabilities and assistance to employers in meeting the requirements of the ADA. This legislation continues to have important implications for work practice.²³ (See Chapter 15 for more information on the ADA.)

In 1992, the AOTA defined work as “all productive activities and included life roles such as homemaker, employee, volunteer, student, or hobbyist.”⁴ This document was replaced in 2000 by the statement “Occupational Therapy Services in Facilitating Work Performance.” This statement asserts that “occupational therapists and occupational therapy assistants contribute to the delivery of services for the promotion and management of productive occupations as well as the prevention and treatment of work-related disability.”²

In 2002, the Occupational Safety and Health Administration (OSHA) unveiled a comprehensive approach to ergonomics to reduce the incidence of musculoskeletal disorders (MSDs) in the workplace. Their four-pronged, comprehensive approach includes guidelines, enforcement, outreach and assistance, and a national advisory committee on ergonomics.

Occupational therapists have traditionally consulted and continue to consult with employers and employees on making recommendations about equipment, posture, and body mechanics to prevent injuries. Ergonomic intervention continues to be an area of many opportunities for occupational therapists who have received additional training and education in the area of ergonomics.

Role of the Occupational Therapist in Work Programs

Occupational therapists and occupational therapy assistants play an important role in helping individuals participate in all aspects of work. According to the *Occupational Therapy Practice Framework: Domain and Process*, second edition, work is an area of occupation that is defined by Mosey as “activities needed for engaging in remunerative employment or volunteer activities,” including the following: “employment interests and pursuits, employment seeking and acquisition, job performance, retirement preparation and adjustment, volunteer exploration, and volunteer

participation.”¹ Occupational therapy practitioners provide services to those with limitations in the area of work performance. The occupational therapist focuses on identifying and analyzing the problem and selecting and/or designing appropriate assessments and interventions for solution of the problem. According to the statement “Occupational Therapy Services in Facilitating Work Performance,” “problems in work performance can arise from physical, sensory, cognitive, perceptual, psychological, social, or developmental changes. Therefore, occupational therapy practitioners provide work-related services in a variety of settings, including, but not limited to, acute care and rehabilitation facilities, industrial sites, and office environments, psychiatric treatment centers and in the community.” Two key services are provided in these settings, “evaluation and intervention, which includes consultative, preventive, restorative, and compensatory services.”² This chapter describes the range of work evaluations and interventions in which occupational therapists are involved in assisting people in actively participating in meaningful work roles.

Industrial Rehabilitation

The range of services provided to injured workers and industry is often encompassed by the terms “industrial” or “occupational rehabilitation.” These terms will be used interchangeably in this chapter. Industrial rehabilitation includes functional capacity evaluation (FCE), vocational evaluation, job demands analysis (JDA), worksite evaluation, pre-employment screening, work hardening/conditioning, on-site rehabilitation, modified/transitional employment, education, ergonomics, wellness, and preventive services. Occupational therapists are integral in providing these services, and this area of practice provides a tangible way for therapists to experience the tremendous reward of seeing lives changed through their efforts. The AOTA has developed a Work and Industry Special Interest Section (WISIS) for those who are involved in or wish to know more about this area of specialization.

Functional Capacity Evaluation

An FCE is an objective assessment of an individual’s ability to perform work-related activity.^{28,52} These functionally based tests have been used since the early 1970s to assist in making return-to-work decisions and were primarily performed by occupational and physical therapists.³⁸ Today, however, the results of such an evaluation can be used in many different ways and they are performed by a multitude of disciplines. Occupational therapists are remarkably qualified to conduct FCEs because of their education and background in task analysis.^{2,3} An FCE can be used to set goals for rehabilitation and readiness for return to work, assess residual work capacity, determine disability status, and screen for physical compatibility before hiring a new employee and case closure.⁷⁵

Ethical Considerations

The FCE is a tremendous tool in the course of rehabilitation that allows a therapist to have objective findings for making thoughtful and appropriate recommendations regarding initiation, continuation, or cessation of treatment or referring the client to another service. Great care must be taken to ensure that the results are not derived lightly because of the enormous impact that such results can have on a person's life.^{45,50}

An FCE usually consists of a review of medical records, an interview, musculoskeletal screening, evaluation of physical performance, formation of recommendations, and generation of a report.⁴⁵ Evaluation of physical performance usually takes the form of assessing the client's physiology, both cardiovascular and muscular endurance, during the course of strength, static, and dynamic tasks. The report usually contains information regarding the overall level of work, tolerance for work over the course of a day, individual task scores, job match information, level of client participation (cooperative or self-limited), and interventions for consideration.^{45,50}

OT Practice Notes

The referral source for an FCE can and does vary. Physicians, attorneys, case managers, insurance carriers, and other therapists are the primary sources for FCE referrals. Some states, institutions, and insurance carriers require a physician's prescription for an FCE; therefore, it is important to be aware of each state's practice act, employer, and insurance carrier guidelines for accepting referrals. Reimbursement also varies with geographic location.

A wide variety of FCEs are currently used in practice today, both commercially available systems and evaluations developed by individual therapists or clinics (Box 14-1, Figure 14-2).

FCEs can be (1) all-inclusive when looking at case closure or settlement; (2) job specific when making a match between a person's abilities and the job description, such as "cashier at XYZ store" or a broader occupational title such as "cashier"; or (3) injury specific, such as an upper extremity evaluation after bilateral carpal tunnel release. Joe, the 26-year-old man with T11 paraplegia, could benefit from a job-specific FCE to determine whether he can meet the physical demands of the alternative job as a laundry attendant.

A well-designed FCE is comprehensive, standardized, practical, objective, reliable, and valid.^{45,50,86}

Twenty Physical Demands of Work

Lifting	Kneeling
Standing	Crouching
Walking	Crawling
Sitting	Reaching
Carrying	Handling
Pushing	Fingering
Pulling	Feeling
Climbing	Talking
Balancing	Hearing
Stooping	Seeing

Data from US Department of Labor, Employment and Training Administration: *Revised dictionary of occupational titles*, vols I and II, ed 4, Washington, DC, 1991, US Government Printing Office.

A comprehensive FCE will include all of the physical demands of work as defined by the *Dictionary of Occupational Titles* (DOT) published by the U.S. Department of Labor and last revised in 1991 (Box 14-2).⁹⁷ The main focus of Joe's FCE will be on the physical demands of work that he can still reasonably do from the wheelchair, such as lifting, sitting, carrying, pushing, pulling, balancing,

reaching, handling, fingering, feeling, talking, hearing, and seeing.

It is also important for the individual being tested to understand the correlation between the test items and the functions of the job. The application of meaningful activity can improve individuals' cooperation during testing and encourage maximum effort. For example, an individual who performs secretarial duties may have difficulty understanding the need to test her ability to climb ladders if she does not actually perform this function during the course of her job.^{1,75}

An FCE needs to be practical in terms of length of testing, cost, space, and report generation.^{50,75}

Standardization in FCEs means having a procedure manual, task definitions and instructions, a scoring methodology, and equipment requirements and set-up.^{50,52,76} This type of structure helps ensure that individuals are being assessed in a fair and consistent manner and demonstrates the effort to minimize observer bias. Verbal instructions are critical in establishing rapport between the evaluator and the individual being tested. During the initial interview, the tone is set for the course of the evaluation, and the individual's trust in the evaluator is implicit in maximizing cooperation and effort during the evaluation.⁵⁰ Objectivity is not limited to weights, distances, heights, or some other numeric quantity; subjective measures can be made objective with operational definitions. Objectivity during the course of an FCE does not exclude clinical judgment and decision making, but it does require the measure to be as free as possible of examiner bias.⁸⁶ This includes physical performance, as well as client cooperation during testing. Objectivity is accomplished through standardization of the testing protocol and a structured scoring methodology.

The most important aspects of an FCE are reliability and validity of the testing protocol. Two types of reliability are deemed to be important in an FCE: interrater and test-retest reliability.⁵² Interrater reliability in an FCE means consistency; if two therapists administer the same test to the same client, will they get the same results?⁴⁵ King and Barrett state that "test-retest reliability or intra-rater reliability refers to the stability of a score derived from one administration of an FCE to another when administered by the same rater."⁴⁵ Being able to establish reliability is the first step in determining the validity or accuracy of the results.⁸⁶ If there is not agreement between evaluators, it is difficult to determine whose results are correct.⁴⁵ Once reliability has been proved, validity can be assessed. The term *validity* is used in many ways, often with significance placed on issues surrounding sincerity of effort. In scientific terms, validity means accuracy; in other words, does the FCE provide results that truly describe how the client can perform at work?^{50,86}

There are several types of validity, with content, criterion (both concurrent and predictive), and construct validity having the most impact on the results of an FCE.^{45,50} Content validity is the easiest to establish in an FCE because

this measure refers to whether the evaluation tests the physical demands of work, as defined by a panel of experts, by job analysis, or by a recognized document such as the DOT.^{50,52,75,97}

Criterion validity refers to whether conclusions can be drawn from the measures taken, and in an FCE this refers to whether a person can actually perform at the level demonstrated during testing.^{45,50,52} Criterion validity is often determined by comparing the methodology in question with a "gold standard"—another instrument that has been proved to be reliable and valid.^{45,50,52} This is difficult to do in an FCE because there are a limited number of available assessments with proven reliability and validity to compare against and because other methods, such as comparing the person's tested ability with the actual work level, can be seriously flawed.^{50,52,56} Criterion validity includes concurrent and predictive validity.

Concurrent validity refers to the ability of a test to measure existing abilities, and in an FCE this would be demonstrated by the test's ability to determine which clients can perform at a given level and which clients cannot perform at a given level.^{45,50,52}

Predictive validity is indicated by the test's capacity to predict future ability and has great value in an FCE by determining who can safely return to work and remain without injury.^{45,50,59} The first FCE to be studied for validity and published in peer-reviewed literature was developed by the occupational therapist Susan Smith and has served as an important contribution to the knowledge base.⁹² Without reliability and validity, a referral source cannot know whether the results of the evaluation would vary if the individual were tested by another therapist or whether the results are accurate.^{45,50,52}

Vocational Evaluations

Work evaluations, or vocational evaluations, are "a comprehensive process that systematically uses work, real or simulated, as the focal point for vocational assessment and exploration to assist individuals in their vocational development."²⁵ According to CARF, the following factors are addressed in the traditional vocational evaluation model: physical and psychomotor capacities; intellectual capacities; emotional stability; interests, attitudes, and knowledge of occupational information; aptitudes and achievements (vocational and educational); work skills and work tolerances; work habits; work-related capabilities; and job-seeking skills.³⁵ These assessments can last from 3 to 10 consecutive days, depending on the goals of the assessment. Vocational evaluators generally conduct these types of assessments in private vocational agencies; however, some occupational therapists have been involved in conducting these evaluations in public and private medical or nonmedical settings as well. Vocational rehabilitation, worker's compensation, and long-term disability carriers pay for these services, but most medical plans do not.

Standardized work samples such as the Valpar Component Work Sample System or the Jewish Employment Vocational Services are used to assess specific skills in the areas of data or things (Figure 14-3). Dexterity tests such as the Bennett Hand Tool, Crawford Small Parts, and Purdue Pegboard are used to evaluate motor skills (Figure 14-4).³⁵ When no standardized work samples are available to assess the specific skills needed for a particular occupation, specially designed situational assessments are also used to create real-life work situations that are related to actual work tasks that would be conducted on particular jobs. For example, a person who is interested in working as a floral arranger could have her motor skills evaluated to see whether she has the coordination, energy, and strength and effort to grip and manipulate tools to cut the stems of flowers and plants and arrange them in floral containers. Individuals can also be evaluated in real worksites and perform actual job tasks that one would perform on the job.

Ethical Considerations

The tasks need to take clients' safety into account and not jeopardize their health or put them at risk for injury by allowing them to perform in an unsafe manner or push beyond their maximum level of performance.⁵⁰

There are generally two different types of vocational evaluation: a general vocational evaluation and a specific vocational evaluation. A general vocational evaluation is a comprehensive assessment to evaluate a person's potential to do any type of work. For an individual who has never worked, does not have a job to return to, or cannot return to the previous job because of a disability, this type of evaluation is beneficial in determining one's aptitudes, abilities, and interests to explore all reasonable options for work. For example, Henry, the roofer who experienced a traumatic brain injury from a fall while working, could benefit most from a general vocational evaluation to explore other options for employment. A general vocational evaluation could help identify other vocational interests and abilities by exploring a person's cognitive and motor skills and physical and mental tolerances that could be applied to a different occupation. A specific vocational evaluation assesses a person's readiness to return to a particular occupation. For a person who has suffered a stroke and wants to return to work as a general office clerk, a specifically tailored vocational evaluation to assess the person's ability to return to this particular type of work can be done. Clerical work samples and specially designed situational assessments that gauge the person's ability to multitask, pay attention to detail, file, answer a telephone, and take messages can be incorporated as an integral component of the vocational evaluation.

Job Demands Analysis

Assessing the physical demands of a job by JDA is often beneficial in the rehabilitation process inasmuch as recommendations for initiation or return to work require objective information about both the client's abilities and the job itself. A well-written job description that includes the essential tasks of the job, physical requirements, cognitive aptitudes, educational requirements, equipment operated, and environmental exposure assists in selecting suitable candidates for employment, setting compensation packages, and making appropriate return-to-work decisions after an injury.⁸

A JDA does not need to be confused with ergonomic evaluations or identification and abatement of hazards. A JDA seeks to define the actual demands of the job, whereas ergonomic evaluations and hazard assessment focus more on work practice and risk for injury secondary to postural or manual material-handling extremes or excesses.⁷ Certainly, these areas can overlap, but it is important to be clear about the differences and the reasons behind the request for information and to use suitable methods for each.⁷

Approaches to a JDA include questionnaires, interviews, observations, and formal measurement.⁷ It is common to interview incumbents or supervisors about the job requirements.⁷⁵ Such an informal approach often leads to narrative descriptions with little functional information and questionable accuracy of demand estimates.^{36,62,75} As with other types of assessment, it is important to have an objective process for analyzing the demands of the job. In the context of attempting to make return-to-work decisions based on matching the results of an FCE with the job description, many FCEs include a JDA component.⁵⁰ However, these are often subjective interviews with the client and can lack accuracy regarding the physical demands.

The occupational therapist who was working with Joe contacted the employer and conducted a JDA to obtain a complete picture of the job demands and requirements of the laundry attendant position. The occupational therapist spoke to the supervisor, as well as to other employees while they were performing the actual job at the worksite. Being able to actually observe the job being done in the real work environment allowed the occupational therapist to gather the information needed to adequately assess Joe's ability to carry out the essential functions of this job.

A standardized classification system is crucial to ensure consistency in terminology and among professionals. The DOT defines the physical demands of work and defines occupations in the United States (Tables 14-1 through 14-3).⁹⁷ It provides definitions of the overall level of work, strength demands, and frequencies of the physical demands.^{97,98} Many countries around the world also refer to the DOT as their primary reference for generic occupational descriptions.

The DOT was last revised in 1991, and in the early 1990s the U.S. government made the decision to not revise

■ **TABLE 14-1** | Definitions for Overall Level of Work

Level of Work	Definition
Sedentary	Exerting up to 10 lb of force occasionally or a negligible amount of force frequently to lift, carry, push, pull, or otherwise move objects, including the human body. Sedentary work involves sitting most of the time but may involve walking or standing for brief periods. Jobs are sedentary if walking and standing are required only occasionally but all other sedentary criteria are met
Light	Exerting up to 20 lb of force occasionally, up to 10 lb of force frequently, or a negligible amount of force constantly to move objects. Physical demand requirements are in excess of those for sedentary work. Even though the weight lifted may be only a negligible amount, a job should be rated light work (1) when it requires a significant degree of walking or standing, (2) when it requires sitting most of the time but entails pushing or pulling arm or leg controls, or (3) when the job requires working at a production rate pace entailing constant pushing or pulling of material even though the weight of the material is negligible. <i>Note:</i> The constant stress and strain of maintaining a production rate pace, especially in an industrial setting, can be and is physically demanding on a worker even though the amount of force exerted is negligible
Medium	Exerting 20-50 lb of force occasionally, 10-25 lb of force frequently, or greater than negligible and up to 10 lb of force constantly to move objects. Physical demand requirements are in excess of those for light work
Heavy	Exerting 50-100 lb of force occasionally, 25-50 lb of force frequently, or 10-20 lb of force constantly to move objects. Physical demand requirements are in excess of those for medium work
Very heavy	Exerting force in excess of 100 lb of force occasionally, in excess of 50 lb of force frequently, or in excess of 20 lb of force constantly to move objects. Physical demand requirements are in excess of those for heavy work

FIGURE 14-4 The Bennett Hand Tool is a dexterity test to assess a person's ability to use hand tools.

the DOT again but instead create a new format for classifying occupations.²⁶ The intent was to create a more generic classification system or framework for defining work. The American Institutes of Research (AIR) was awarded a contract by the Utah Department of Employment Security on behalf of the U.S. Department of Labor, and they developed O*NET, an online, searchable database for information about occupations. Although the format includes an enormous amount of data, its definitions can make it difficult for rehabilitation professionals to use in a qualitative

■ **TABLE 14-2** | Definitions of Physical Demand Frequencies

Physical Demand Frequency	Definition
Never	Activity or condition does not exist
Occasionally	Up to $\frac{1}{3}$ of the day
Frequently	$\frac{1}{3}$ to $\frac{2}{3}$ of the day
Constantly	$\frac{2}{3}$ to full day

Data compiled from US Department of Labor, Employment and Training Administration: *Revised dictionary of occupational titles*, vols I and II, ed 4, Washington, DC, 1991; and US Government Printing Office; US Department of Labor, Employment and Training Administration: *The revised handbook for analyzing jobs*, Indianapolis, Ind, 1991, JIST Works.

fashion.⁷⁴ O*NET, however, is not intended to take the place of the DOT but rather to provide a more structured approach for “career exploration.”⁷⁴ It is recommended that both the DOT and O*NET be consulted when obtaining occupational information.²⁶

In terms of recent legislation that has an impact on employment law, both the ADA and the Equal Employment Opportunities Commission (EEOC) define essential

■ **TABLE 14-3** | **Strength Demands of Work: Frequency of Force Exertion or Weight Carried**

Strength Rating	Occasional (Up to 1/3 of the Day)	Frequent (1/3 to 2/3 of the Day)	Constant (Over 2/3 of the Day)
Sedentary	10 lb	Negligible	Negligible
Light	20 lb	10 lb	Negligible
Medium	20-50 lb	10-25 lb	10 lb
Heavy	50-100 lb	25-50 lb	10-20 lb
Very heavy	Over 100 lb	50-100 lb	20-50 lb.

Data from US Department of Labor, Employment and Training Administration: *Revised dictionary of occupational titles*, vols I and II, ed 4, Washington, DC, 1991, US Government Printing Office.

tasks as being the reason that the job exists.^{6,7} The ADA further defines essential tasks as those that are highly specialized (i.e., the reason that the incumbent was hired to perform the job) and that there are a limited number of people available at the job site to perform the tasks.⁶ During the course of a JDA it is important to distinguish between tasks that are essential and those that are not. This can be challenging because it is a nontraditional way for both the employee and the employer to look at the job. It is important that both hiring and return-to-work decisions be based on job descriptions that define the essential tasks to be congruent with both the ADA and EEOC language.

OT Practice Notes

In preparation for an observational JDA, an interview can be conducted on the telephone to glean initial information about the job to allow adequate research on the job title and equipment. Advance preparation also aids in selecting the personal protective equipment that needs to be worn while performing the analysis.

Jobs are composed of the tasks that are performed, the physical demands that make up the tasks, and the frequency with which the physical demands are performed, including weights handled, forces exerted, and distances both ambulated and reached.⁷ The frequency of each physical demand must be weighted appropriately for the given duration of each task because there is often a significant difference in the amount of time spent on each task during the workday. For example, the job of “loader” in ABC warehouse is

composed of two tasks: (1) loading crates with boxes and (2) wrapping the crate with packing tape when loaded. The loader completes 48 cycles of loading and taping in an 8-hour shift, with loading the crate taking approximately 80% of the work shift. The boxes weigh 10 lb each. To correctly assess the overall level of work, the amount of weight lifted must be determined, as well as the frequency of the manual materials handling.

Task 1 is composed of the physical demands of lifting, carrying, stooping, walking, reaching, handling, and standing. Task 2 is composed of walking, reaching, handling, fingering, and standing. To correctly sum the amount of the physical demands for the job of loader, one must determine how much time is spent on each physical demand within each task and then account for the proportion of the time that the task is performed during the workday. This type of assessment can be performed manually, as well as with the application of various software protocols available in the marketplace.

Whatever methods are selected, clinicians should strive to provide an accurate picture of the job and its requirements, with an emphasis on functional demands for easier application in the rehabilitation continuum.

Ethical Considerations

Whatever methods are selected, clinicians should strive toward providing an accurate picture of the job and its requirements with an emphasis on functional demands for easier application in the rehabilitation continuum.

Work Hardening/Work Conditioning

The idea of using work for rehabilitation is at the very core of occupational therapy. In the 1970s, the idea of occupational rehabilitation developed from the necessity of improving strategies to control work-related injuries.^{19,44,51,73} Work hardening was first illustrated conceptually by Leonard Matheson, a psychologist at Rancho Los Amigos who worked very closely with Linda Dempster, an occupational therapist, in developing his material.^{44,51,73} The goal was then and still remains rehabilitation of injured workers, maximization of their function, and returning them to work as quickly and safely as possible. The delivery system for this type of rehabilitation has evolved over time from a lengthy hospital-based program, to structured interdisciplinary programs in outpatient settings, to the more progressive partnership between outpatient intervention and transitional work, as well as to rehabilitation occurring at the workplace in company-sponsored clinics. In the 1980s, CARF developed guidelines for work-hardening programs and offered certification for a fee through adherence to their guidelines and periodic surveys.^{19,44,51,73} In

1991, a committee from the American Physical Therapy Association (APTA) developed another set of principles for clinics that wanted to follow recognized standards but did not desire to undertake the CARF accreditation process.^{19,44,51}

Work hardening refers to formal, multidisciplinary programs for rehabilitating an injured worker.^{19,44,51,73} The disciplines represented on the team can often include occupational and physical therapists and assistants, psychologists, vocational evaluators and counselors, licensed professional counselors, addiction counselors, exercise physiologists, and dieticians.^{19,44,51} The programs typically range from 4 to 8 weeks and consist of an entry and exit evaluation (usually an FCE or a derivative thereof), a job site evaluation, graded activity, both work simulation and strength and cardiovascular conditioning, education, and individualized goal setting and program modification, with the goal of return to work at either full or modified duty.^{19,44,51} Actual equipment from the job is preferred during the work simulation to maximize cooperation of the worker and more closely replicate the actual demands of the job.⁴⁴ Work conditioning is more often defined as physical conditioning alone, which covers strength, aerobic fitness, flexibility, coordination, and endurance and generally involves a single discipline.^{19,42,44} Both approaches involve evaluation of the worker to establish a baseline from which to plan treatment and measure progress.

Motivational issues are a constant concern and are often thought to be at the forefront of unsuccessful return to work.⁹¹ Maladaptive behavior regarding return to work can develop in an injured worker as a result of depression, financial issues, family pressures, and feelings of being manipulated by the “system.”⁹¹ This can lead to employer mistrust, interest in litigation, and a need to exaggerate symptoms. Fraud on the part of the injured worker is also an issue.⁹¹ Employer indifference is a concern and can have a remarkable impact on a worker’s attitude toward returning to the job.⁹¹ Surveys of attitudes among employers have indicated that activity on the part of the employer can affect costs; as many as 90% of respondents indicated that how well the employee perceived that he or she was treated at the time of the injury was associated with decreased costs as a result of the injury.⁹¹

Think about Lorna, the upholsterer who is experiencing hand problems, and the difficulties that she is experiencing at work. An occupational therapist could evaluate her symptoms and her job description and make suggestions to the employer about modifying her job demands so that she can continue to work during treatment. This demonstrates to Lorna that her well-being matters and can help her have a positive outcome with treatment.

Ensuring a positive outcome for the injured worker requires early intervention and a customized plan of treatment to address the various areas affected by the injury, including both physical and psychosocial.⁹¹ Incorporation of a multidisciplinary team allows the patient to have the benefit of many areas of expertise working toward his or her common good. Intervening and initiating the rehabilitation program as soon as possible following the injury dramatically increase the chance for successful return to work. Based on a study of 5620 worker’s compensation beneficiaries, there was a 47% return-to-work rate in workers referred to rehabilitation within the first 3 months after injury, with a cost savings of 71%. When referred during months 4 through 6, the rates dropped to 33% for return to work and 61% for cost savings. For those referred beyond 12 months after injury, only 18% returned to work and cost savings dropped to 51%.⁹¹

Transitional work and modified duty programs involve a combination or a progression of acute rehabilitation and return to work at a level consistent with the individual’s current ability, with the goal of returning to work at full duty or maximizing the individual’s work capacity. An example of transitional duty would have a worker performing work-conditioning activities under supervision in an outpatient clinic from 8 to 10 a.m., going to the worksite and performing the less physically demanding portions of his job from 11 a.m. to 1 p.m., breaking for lunch, and then returning to the “lighter” duties of the job for the duration of the shift. More regular duty activities are added under supervision as the worker’s skill and strength improve, with eventual return to full duty. This type of structure provides a much better environment for the worker to be involved in the work culture and allows coworkers and supervisors to participate in job modification and overall recovery of the injured worker.⁹¹ Modified duty follows a similar path but typically does not include the clinical portion of the day. There are challenges to return to work at less than full duty, however, with some employers not wanting workers to return to the site unless they are at “100%.” It is imperative to demonstrate the benefit to the company and the employee, both economically and psychologically, of early transitional return to the long-term success of returning the employee to the workforce.

Industrial rehabilitation programs will continue to change as the tides of economy, industry needs, and legislation move forward. Occupational therapists are key in directing the changes that lie ahead.

OT Practice Notes

It is essential for the therapist to encourage the employer to be involved with the employee after the injury, investigate injury claims that are worthy of investigation, call to inquire about how the employee is feeling, and consider modified duty and transitional work options to promote successful return to work.

Worksite Evaluations

Worksite evaluations are on-the-job assessments to determine whether an individual can return to work after onset of a disability or whether a person can benefit from reasonable accommodations to maintain employment.^{41,95} For example, a man who worked at a manufacturing company as a machine operator incurs a stroke and the employer is willing to take him back as long as he can meet the physical and cognitive demands of the job. An occupational therapist can go to the worksite to evaluate the person's ability to safely and adequately operate the machinery and carry out the essential functions of the job. Consider another example. A person who previously worked as an office clerk without any difficulty is now experiencing extreme fatigue, pain, and muscle weakness with repetitive tasks as a result of post-polio syndrome. This person could benefit from a worksite evaluation to identify reasonable accommodations to allow her to continue working at this job while minimizing her symptoms. Several factors are assessed at the worksite with the worker present: the essential functions of the job, the functional assets and limitations of the worker, and the physical environment of the workplace.⁵⁵

A worksite evaluation is usually conducted after a job analysis has been done. Larger companies may already have information on job analyses done on specific jobs. If a job analysis has not been done, the occupational therapist can conduct a job analysis if the employer is willing, or a job description could be obtained from the employer before going out to the worksite. If there is no written job description, a phone call to the supervisor/manager of the worker should be made to obtain verbal information regarding the essential functions of the job and the physical and cognitive requirements for the job. After this information is obtained, the occupational therapist schedules a time with the employer and the worker to meet at the worksite. This is exactly what happened with Joe as he prepared to switch from the job of janitor to laundry attendant at the hotel and spa. After the occupational therapist conducted the job analysis, Joe met with both the occupational therapist and the employer at the worksite for the worksite evaluation.

When the occupational therapist meets the employer and worker at the worksite, the occupational therapist assesses the work, the worker, and the workplace.⁴⁷ The evaluation begins with an analysis of the essential functions that may require accommodation.⁹⁵ The occupational therapist should have an idea of what these functions are based on the information obtained before going to the worksite. The desired outcome of the work tasks should be emphasized, not just the process of performing the essential function.⁹⁵ The occupational therapist should find out certain details, such as how the outcome will be affected if a particular task is done incorrectly, in a different sequence, or omitted; whether there are quotas, standards, or time constraints that must be met⁷⁹; and whether the frequency with which a task is done will affect the outcome.

Activity analysis is a useful tool for evaluating a person at the worksite.¹¹ It can be used to address all areas, including motor, sensory, cognitive, perceptual, emotional and behavioral, cultural, and social. When assessing a person's ability to carry out the essential functions of the job, the occupational therapist has expertise in breaking down the tasks and determining the parts of the task with which the worker is having difficulty or may have difficulty over the course of a workday. The occupational therapist can suggest accommodations to allow the worker to carry out the essential functions of the job.

The final step in the worksite evaluation is to assess the work environment. The environment outside the immediate work area should be evaluated (parking if driving or access to public transportation; access into the building, break room, and restroom), as well as the workstation itself. All work areas that the worker may use need to be investigated to identify obstacles and solutions to increase accessibility. The location and placement of machines, supplies, and equipment that the worker needs to access should be assessed, as well as other environmental factors such as lighting, temperature, and noise level.

Taking photographs or video recordings at the worksite can be very useful; however, permission must be obtained from the employer as well as the worker to do so. The occupational therapist should also bring a tape measure to measure the height of work surfaces, width of doorways, and other factors, depending on the person's needs. Drawing a layout of the work area to scale on graph paper is also very helpful, especially when the worker is in a wheelchair. Critical measurements can be recorded on the diagram.

The outcome of the worksite evaluation is to determine whether the person can safely and adequately carry out the essential functions of the job with or without any reasonable accommodations. Ergonomic principles (addressed in the following section) should be considered and applied when recommending reasonable accommodations. The process of identifying reasonable accommodations requires cooperation between the person with the disability, the employer, and the occupational therapist.⁷⁹ Each person has valuable insights and information to contribute to the process of identifying the best accommodations. The Job Accommodation Network (JAN) is a service provided by the Office of Disability Employment Policy (ODEP) of the U.S. Department of Labor's and is the best resource for assisting employers and disabled workers in making reasonable accommodations (<http://askjan.org>).⁸⁷ Their Website points out that most job accommodations are not usually expensive. According to the JAN, more than half of all accommodations cost nothing. The JAN offers one-on-one guidance on workplace accommodations, the ADA, and self-employment options for people with disabilities. JAN consultants can be contacted both over the phone and online. JAN's toll-free number is (800)526-7324. The occupational therapist analyzes the need for modification of the equipment that the worker is using or modification of the

workplace to help the person perform with greater efficiency, effectiveness, and safety.⁵

After the worksite evaluation is completed, a report is prepared and sent to the qualified employee, the referring party, and the employer. The problem areas that relate to the essential job functions should be listed clearly, as well as the accommodations necessary to solve them. If training is necessary to use a recommended accommodation, sources for the training should be identified. If commercially available equipment is recommended, exact model numbers, local sources, and approximate expenses should be provided.⁹⁵ If custom equipment needs to be fabricated, sources, cost estimates, and the amount of time required to fabricate the equipment should be included as well. The report should summarize the findings of the evaluation and the accommodations that were recommended.

After Joe's worksite evaluation, it was determined that he could safely and dependably carry out the essential functions of the job from his wheelchair. Just one accommodation was recommended and implemented. Since it gets very hot in the laundry room and Joe is sensitive to the heat, the employer agreed to purchase additional fans to ventilate the room better, as well as allow the door to the laundry room to be propped open. The employer agreed to schedule Joe's shift in the evening or early morning when it was cooler to avoid having to work in the heat of the day.

The occupational therapy practitioner thus evaluates the worker, the work, the workplace, and the relationship among them. Therapeutic intervention is used when deficits in performance are found. The occupational therapist can modify the way that the worker performs the work or modify the work environment to allow the worker to perform optimally.

Ergonomics

All aspects of the domain of occupational therapy must be in harmony for people to fully engage in the occupation of work. The activity demands of the job and the context in which the job is performed must fit with the employee's abilities and physical/psychosocial makeup. Any mismatch between the activity demands of the job and context, individual client factors, and performance patterns will interfere with successful execution of the appropriate performance skills required to do the job.

Occupational therapists use the science of ergonomics to assist clients in fully engaging in the occupation of work. Ergonomics addresses human performance and well-being in relation to one's job, equipment, tools, and environment. The goal of ergonomics is to improve the health, safety, and efficiency of both the worker and the workplace.⁶⁷ The term *ergonomics* is derived from the Greek words *ergos*, meaning "work," and *nomos*, meaning "laws"—hence the laws of work.²⁰ The Polish educator and scientist Wojciech Jastrzebowski (1799-1882) introduced the term *ergonomics* in the literature about 150 years ago.¹⁹ However, the concept of

ergonomics—that there is some connection between physical well-being and the type of work performed—is as old as humanity: "From the very first tool of the Stone Age, humans have tried to find better ways of working, taking advantage of human talents and making up for human shortcomings."⁵⁶

The idea behind ergonomics is that every worker brings his or her own unique set of performance skills, performance patterns, and client factors to the workplace. Many times work settings and work processes are designed to satisfy space and budget limitations and the demands of productivity and aesthetics. When these designs fail to take into account the people who will be using the work setting and process, injury and inefficiency can result. Finding a way to match individual employees' strengths and limitations with the context and activity demands of a job can improve both worker safety and workplace productivity.

The principles of ergonomics help address a variety of work-related issues. Common issues include workplace and work process design, work-related stress, the disabled and aging workforces, tool and equipment design, architectural design, and accessibility. Ergonomic intervention can be applied proactively, preventing problems before they occur, or reactively, adjusting the worker-job-context "fit" when problems do occur. Many occupational therapists use ergonomic principles as part of their comprehensive rehabilitation or wellness and prevention client-centered programs. A few occupational therapists specialize in ergonomics and become professional ergonomists.

With regard to ergonomic services, the occupational therapist's client base may include the individual worker, workers in the context of employee groups, and/or the employer itself. The environment for an occupational therapist providing ergonomic services is generally at the client's place of work. These occupational therapists must become skilled in navigating what can be an unfamiliar business world with its unique lingo, social norms, and traditions. However, an occupational therapist providing ergonomic services shares a similar focus with occupational therapists in all areas of practice, that is, a focus on marketing and sale of the product (in ergonomics—wellness), cost-effectiveness, definable outcomes, and client satisfaction.

Occupational therapists are not the only professionals suited to specialize in the field of ergonomics. Ergonomics professionals come from a variety of backgrounds. It is not unusual to see ergonomists who have been academically trained in industrial hygiene, engineering, safety, business administration, human resources, medicine, physical/occupational rehabilitation, psychology, architecture, epidemiology, or computer science.¹⁸ For the occupational therapist, the road to becoming a professional ergonomist can take many paths. [Box 14-3](#) outlines a variety of methods for acquiring advanced knowledge and certification in the field of ergonomics.

For occupational therapists interested in the field of ergonomics, the holistic nature of occupational therapy training

Box 14-3

Education and Training Opportunities in Ergonomics

Education and training beyond occupational therapy entry-level practice are necessary for achieving advanced competence in ergonomics.

University-sponsored graduate certificate programs in ergonomics are available through Texas Women's University, Cleveland State University, University of Central Florida, and University of Massachusetts. These graduate-level courses typically require four to five courses for a total of 12 to 16 credit hours.

Continuing education providers offer several-day courses that on completion, allow the occupational therapist eligibility for certifications such as the Ergonomics Evaluation Specialist available through Roy Matheson and Associates, Inc. (www.roymatheson.com), and the Certified Ergonomics Assessment Specialist

available through the Back School of Atlanta (www.backschoolofatlanta.com).

The Oxford Research Institute (www.oxfordresearch.org) offers the following advanced-level certifications: Certified Industrial Ergonomist, Certified Associate Ergonomist, and Certified Human Factors Engineering Professional.

The Board of Certification in Professional Ergonomics (BCPE) (www.bcpe.org) offers the highest level of certification in the field of ergonomics—the Certified Professional Ergonomist. Other advanced-level certifications available through the BCPE include Associate Ergonomics Professional, Certified Ergonomics Associate, Certified Human Factors Professional, and Associate Human Factors Professional.

Data from Snodgrass J: Getting comfortable: developing a clinical specialty in ergonomics has its own challenges and rewards, *Rehab Manag* July;24, 2004.

Box 14-4

Anthropometry

Anthropometry is the study of people in terms of their physical dimensions. It includes the measurement of human body characteristics such as size, breadth, girth, and distance between anatomic points. It also includes segment masses, centers of gravity of body segments, and ranges of motion, which are used for biomechanical analysis of work and postures. Standard anthropometric tables are available to assist designers of work areas, work surfaces, chairs, and equipment. The tables outline the average dimensions of adult men and women in the 5th, 50th, and 95th percentiles of the population. Ideally, designs should “fit” a wide range of persons between the 5th percentile (smallest people) and the 95th percentile (largest people). Retail merchandise labeled “ergonomic” is based on these anthropometric dimensions. In practice, however, few designs meet the needs of such a wide range of people, which explains why expensive equipment labeled “ergonomic” does not always produce the desired results. Professional ergonomic intervention seeks to create a better “fit” for the individual user.

Workstation Design

An example of ergonomic chair design based on anthropometric data is presented in Figure 14-7, A.

From Eggleton E, editor: *Ergonomic design for people at work*, vol 1, New York, NY, 1983, Van Nostrand Reinhold.

is an asset. The occupational therapist immediately understands that the goal of ergonomic intervention, or achieving a perfect fit between an individual worker and his or her job and context, is never simplistic. In the domain of occupational therapy, the worker component is composed of performance skills, performance patterns, and client factors (Box 14-4). The job component is composed of activity demands,

both of the job tasks and of tools/equipment. Engaging in the occupation of work occurs in a variety of contexts, including the environment and organization, as well as the worker's personal, cultural, social, and spiritual contexts.

Observing independent aspects of the domain offers the observer limited insight. Rather, it is the interactions between the various aspects of the domain that reveal the

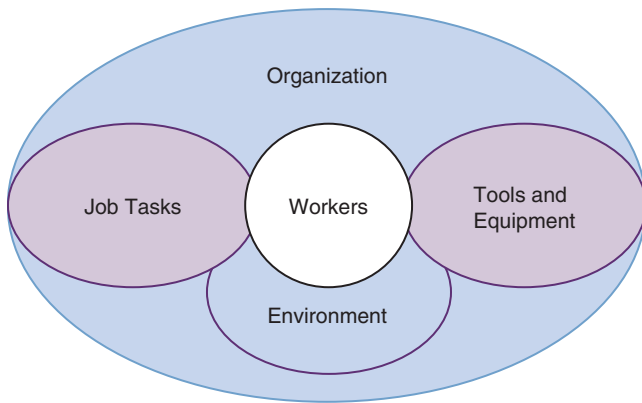

FIGURE 14-5 Dahl's ergonomics work system.

(From Dahl R: *Ergonomics*. In Kornblau B, Jacobs K, editors: *Work: principles and practice*, Bethesda, Md, 2000, American Occupational Therapy Association.)

whole picture. This way of looking at worker performance via the interactions of all aspects of the domain of occupational therapy is known as system theory. Rannell Dahl, MS, OTR, explains that the “components of work systems are workers, job tasks, tools and equipment, work environments, and organizational structure, and the interactions among these components.”¹⁸ Dahl offers an excellent schematic of this concept of the ergonomics work system (Figure 14-5).

In his groundbreaking text *Conceptual Aspects of Human Factors*, David Meister explained that in human factors (ergonomics), the system concept is the belief that human performance in work can be meaningfully conceptualized only in terms of organized wholes. He emphasized the fundamental Gestalt ideas that “the whole is more than the sum of its parts, that the parts cannot be understood if isolated from the whole, and that the parts are dynamically interrelated or interdependent.”⁵⁹ Occupational therapists understand that one can conceive of worker performance only in terms of the interaction between performance skills, performance patterns, context, activity demands, and client factors. The *Occupational Therapy Practice Framework: Domain and Process* supports this concept: “Engagement in occupation as the focus of occupational therapy intervention involves addressing both subjective (emotional and psychological) and objective (physically observable) aspects of performance. Occupational therapy practitioners understand engagement from this dual and holistic perspective and address all aspects of performance when providing interventions” (p. 628).¹

Occupational therapist Jeffrey Crabtree adds that it is “the subjective meaning of the interactions in the human-work-machine-environment model [that] is central to occupational therapy and ergonomics.”¹⁶

The system theory does not discount the importance of the adequacy of independent aspects of the domain of occupational therapy. The quality of the work system can suffer

if there are deficiencies or deviations in performance skills, performance patterns, context, activity demands, or individual client factors. Dahl explains that each component of the ergonomics work system (see Figure 14-5) “has its own set of characteristics that affect the performance of the work system”¹⁸ as a whole. It is here that ergonomic assessment and intervention seek to make a difference in the quality of our clients’ engagement in the occupation of work. The ergonomic practitioner modifies and strengthens certain aspects of the system with the goal of enhancing the overall quality of the work system interactions (i.e., improving the fit between the worker and his or her job).

Although it is beyond the scope of this chapter to comprehensively review the complete array of ergonomic design considerations, the following is a discussion of selected ergonomic design principles. There are, however, a multitude of resources for occupational therapists interested in learning more about the science of ergonomics. The authors of this chapter direct you to the references listed at the end of the chapter. Additionally, readers may be interested in the ergonomics information available through OSHA (www.osha.gov) and NIOSH (www.cdc.gov/niosh/).

When discussing ergonomic design it is important to understand that it is the relationship between the worker and work equipment, tools, or processes that is the problem, not any particular characteristic on either side. This can be confusing to an employer who orders expensive ergonomic tools and equipment for his or her workers and is disappointed when the workers continue to suffer work-related injuries and illnesses. The specialists in ergonomics must explain to their clients that a tool or piece of equipment is never in itself ergonomic; rather, it is the fit between a particular piece of equipment, tool, or process and the intended user of that equipment, tool, or process that creates a proper ergonomic situation.

Workstations

There are three major types of workstations: seated, standing, and combination sit/stand. The type of task being performed dictates the best choice. Seated workstations are best for fine assembly and writing tasks and when all required task items can be supplied and handled within comfortable arm’s reach in the seated work space. Items handled in a seated workstation should not require hands to work more than 6 inches (15 cm) above the work space, and the items handled should not weigh more than 10 lb (4.5 kg). For this reason, the height of the work surface should be above elbow height for precision work. Standing workstations are appropriate for all kinds of work tasks but are preferred when downward force must be exerted (i.e., packaging and wrapping tasks) and when frequent movement or multilevel reaching is required around the work area. Items weighing more than 10 lb (4.5 kg) should be handled in a standing workstation. Work surface heights for heavy work should be 4 to 6 inches (10 to 15 cm) below elbow height for heavy work. The combination sit/stand

workstation is best for jobs consisting of multiple tasks, some best done sitting and some best done standing.²² Figure 14-6 shows the recommended dimensions for both a seated workstation and a standing workstation.

Seating

If seating is required, the design of the chair is of paramount importance for worker comfort and support. Poor seating leads to poor working posture. The result can be fatigue, musculoskeletal injury, and/or poor work performance. Although chair preference is highly variable among the population, there are some basic characteristics to consider. Chairs should be easily adjustable for height, backrest position, and seat pan tilt. Appropriate lumbar support is important. Seats upholstered in woven fabric are cooler and more comfortable in warmer work environments.²² Chair casters should match the flooring (i.e., hard floor versus carpet casters). A seat pan that is too deep will cut into the back of the leg and compromise lower extremity circulation. Sitting in a chair without the feet supported will also cause pressure on the back of the legs. When the worker is seated at the workstation and performing a task, both feet should be supported on the floor or a footrest. Choosing a seat pan with a front-edge “waterfall” design will also decrease pressure on the back of the legs. Armrests are an area of controversy but should generally be provided when the work task requires the arms to be held away from the body.³⁷ Figure 14-7, *A*, illustrates the recommended chair characteristics for generalized seated workstations. Figure 14-7, *B*, illustrates a seated position for computer users.

Visualizing the Job Task

Visual factors to consider are the location of task items and lighting. Again, recommendations depend on the type of task being performed. The goal is clear, direct viewing without straining the eyes or neck. Tasks should be located as directly in front of the worker as possible. Tasks requiring close-range viewing should be positioned 6 to 10 inches (15 to 25 cm) above the work surface. Minimum and maximum viewing distances depend on the size of the object being viewed. Bifocal eyeglass wearers have difficulty observing any object closer than 7 inches (18 cm) in front of the body that is above eye level or near the floor. Additionally, bifocal wearers have difficulty focusing on signs or dials located 24 to 36 inches (61 to 91 cm) in front of them.²⁰

Three basic lighting factors need to be considered for performance of work: quantity, contrast, and glare. Lighting should be adequate for the worker to perform the job task, but not so bright that it causes discomfort. General work environment illumination is typically provided by sunlight and light fixtures at 50 to 100 foot-candles (ft-c). Computer users may find that this amount of illumination washes out the display screen and causes eyestrain. The recommended illumination level for computer workstations is 28 to 50 ft-c. Too much contrast between the task items and the

surrounding areas can also stress the eyes. Therefore, the illuminance between the task items, equipment, horizontal work surface, and surrounding areas should be minimized. Finally, the color and finish of the workstation walls and equipment, as well as the arrangement of the lighting sources, should all be designed to avoid reflective glare on the job task (Figure 14-8).⁷²

Tools

Tools should be designed to protect the worker from hand vibration, extreme temperatures, and soft tissue compression. Therefore, handles on tools are essential. “A properly designed tool handle should isolate the hand from contact with the tool surface, enhance tool control and stability, and serve to increase the mechanical advantage while reducing the amount of required exertion.”⁸¹ Since the average worker’s hand is 4 inches (10 cm) across, the length of the tool handle must be at least 4 inches to avoid unnecessary pressure on the palm of the hand. Handles of scissors and pliers should be spring-loaded to avoid trauma to the back and sides of the hands.⁸¹

Tool design should minimize muscular effort and awkward posturing of the upper extremity. Whenever possible, opt for power tools to minimize the human effort required. Choose tool shapes that allow the wrist to stay straight and the elbow to stay bent and close to the body during use. The shape of the tool will depend on the job task and work surface (Figure 14-9). Tools that weigh between 10 and 15 lb (4 to 6.5 kg) cannot be held in a horizontal position more than a couple of minutes without the worker experiencing pain and fatigue. Suspension systems and counterweights should be designed for use with heavy hand tools.⁸¹

Whole-body vibration can cause back pain and performance problems when the workstation vibrates, as in the case of long-distance truck drivers and in production industries using high-powered drills or saws in the work area.¹⁴ Hand-arm vibration has been linked to vascular compromise, peripheral nerve damage, muscular fatigue, bone cysts, and central nervous system disturbances.²⁹ The effects of hand tool vibration should be minimized as much as possible. Use antivibration tools at low speeds when available. Ensure that tool handles and gloves fit the workers’ hands. Train workers to grip tool handles as lightly as possible and allow the tool to do all the work instead of the worker adding force behind the tool. Encourage frequent rest breaks and educate workers that smoking increases the risk for vibration-related hand problems.^{18,29}

Materials Handling

Concerns regarding handling materials center on back injury and include lifting, pushing, pulling, bending, and twisting. The heavier the material, the more risk for injury. Low back injuries are seldom the result of a single traumatic episode but rather the result of repeated microtrauma that ultimately leads to injury.³³ Therefore, workstation and

Optimal work surface height varies with performed:
 Precision work = 31–37 inches
 Reading/writing = 28–31 inches
 Typing/light assembly = 21–28 inches
 Seat and back rest heights should be adjustable as noted in chair requirements

A

Workbench heights should be:
 Above elbow height for precision work
 Just below elbow height for light work
 4–6 inches below elbow height for heavy work

B

FIGURE 14-6 Recommended dimensions of workstations. **A**, Seated work. **B**, Standing work.

(From Cohen AL, Gjessing CC, fine LJ, Bernard BP, McGlothlin JD: *Elements of ergonomics programs: a primer based on workplace evaluations of musculoskeletal disorders*, Washington, DC, 1997, US Government Printing Office.)

FIGURE 14-7 A, Recommended chair characteristics. Dimensions are given from both front and side views for width (A), depth (E), vertical adjustability (D), and angle (I) and for backrest width (C), height (F), and vertical (H) and horizontal (G) adjustability relative to the chair seat. The angle of the backrest should be adjustable horizontally from 12 to 17 inches (30 to 43 cm) by either a slide adjust or a spring and vertically from 7 to 10 inches (18 to 25 cm). Adjustability is needed to provide back support during different types of seated work. The seat should be adjustable within at least a 6-inch (15-cm) range. The height of the chair seat above the floor with this adjustment range will be determined by the workplace, with or without a footrest. B, Proper seated position for a computer user.

(A, From Eggleton E, editor: *Ergonomic design for people at work*, vol 1, New York, NY, 1983, Van Nostrand Reinhold; B, from Occupational Safety and Health Administration: *Working safely with video display terminals*, Washington, DC, 1997, US Government Printing Office, available at: www.osha.gov/Publications/OSHA3092.pdf.)

work process design becomes integral for the safety of materials handling workers.

Design considerations for heavy lifting include the use of mechanical assist devices whenever feasible (e.g., use of a Hoyer lift for moving immobile patients in the hospital). When mechanical assist devices are not available, training in proper lifting technique and proper body mechanics is important to promote worker safety. Providing workers with back support is controversial, but many believe that the use of an elastic back support “has a preventative function, protecting the tissues ... thus making injury less common.”⁴⁶ Training workers and providing them with back support is only effective, however, when “supervisors and managers encourage the use of safe procedures and write policies that enforce them.”⁸⁵

The following suggestions are useful for addressing safe handling of materials. Design workstations to keep large

items that require lifting off the floor. Provide platforms that will keep items at mid-thigh height to allow workers to stand nearly erect for lifting. Provide foot clearance so that workers can get as close to the item as possible when lifting and face the load head-on. Adjustable lift tables are excellent for this purpose. Objects should be against the torso during the lift to minimize force on the spine. Workers should never be forced to twist their torsos to lift an object. Use carts or conveyors to transport heavy materials instead of carrying them. Orient packages for easy pick-up and provide adequate handles or handhold cutouts on packages.¹⁸

As stated earlier, these ergonomic design principles can be applied proactively to work situations to prevent problems before they even occur. For many occupational therapists, however, introduction to ergonomic considerations comes secondarily as part of a comprehensive

FIGURE 14-8 Lighting position considerations for computer workstations. Most of these lighting position principles can be applied to workstations in general. (From Occupational Safety and Health Administration: *Working safely with video display terminals*, Washington, DC, 1997, US Government Printing Office, available at: www.osha.gov/Publications/osha3092.pdf.)

rehabilitation program for injured workers. Following a work-related injury, ergonomic intervention is essential to the client's successful re-engagement in the occupation of work. Without the ergonomic intervention aspect, the rehabilitation process cannot be considered complete.

A significant amount of effort goes into the rehabilitation of an injured worker. Physical injuries require the attention of a medical doctor to prescribe rest, medications, and rehabilitative therapies. The occupational therapist will provide acute care of the injuries by fabricating splints, instructing workers in stretching and strengthening exercise, and using physical agent modalities such as heat and ice to calm the soft tissues in preparation for functional rehabilitative activities. Other aspects of the occupational therapy plan include educating the injured worker about the nature of the injury and training in general body mechanics and personal injury management strategies to help prevent recurrence of injury on return to work. In some cases, the injured worker will require specialized conditioning before return to work and will be referred to a work-hardening program.

When the client is ready to return to work, it is important to remember that an injured worker cannot be safely returned to the same job without ergonomic intervention.

It seems obvious that returning an injured worker to the same conditions that caused the injury will certainly result in reinjury if not eliminated before the employee's return to work. However, ergonomic intervention is sometimes overlooked as an integral part of the rehabilitation program. The goal of ergonomic evaluation and intervention in an injured employee's work environment is to eliminate factors that contributed to the injury in the first place. If we do not eliminate the major cause of the original injury, it will not be long before the worker suffers a recurrence. If that happens, we have failed as occupational therapists to provide a successful rehabilitation process.

Ergonomic Evaluation

The ergonomic evaluation is an important assessment and intervention tool when used as part of a comprehensive rehabilitation or injury prevention program. This tool can be used along the entire continuum of prevention services. Ergonomic evaluation can be performed during workstation and work methods planning to assist in efforts to prevent worker injury. Ergonomic evaluation can also be performed for workers in whom symptoms of a work-related musculoskeletal disorder (WMSD) develop and for workers who come to therapy for rehabilitation and are

FIGURE 14-9 Hand tool design and wrist posture.

(From Armstrong T: *An ergonomic guide to carpal tunnel syndrome*, Akron, Ohio, 1983, American Industrial Hygiene Association.)

ready to return to work, the goal being to prevent reinjury. Finally, ergonomic assessment can be useful in modifying a job in preparation for a disabled worker's return to work with the goal of preventing further injury related to the disability.

The ergonomic evaluation should begin with the occupational therapist scheduling a time to meet with both the worker(s) to be assessed and the direct supervisor of the work area. The evaluation should be scheduled during the normal work hours of the worker(s). The goal is to obtain the best understanding of what actually occurs during a typical work shift, so the conditions should be closely approximated. It is extremely important that the actual worker(s) be present. The purpose of the evaluation is to look at the fit between the specific worker(s) and the specific job methods, equipment, and set-up. If any element is missing, the evaluation is of little or even no value.

Ideally, the occupational therapist evaluator will arrive at the worksite and meet first with the direct supervisor of the work area to be evaluated. The supervisor will be asked to give an overview of the circumstances leading up to the request for ergonomic evaluation. The occupational therapist will want to know what kinds of injuries are occurring

in the work area, when the problem started, and how many employees have been affected. The supervisor will be able to review how the organization has dealt with the problem to date. Frequently, the supervisor will also describe what sorts of psychosocial and environmental influences may be affecting the situation. Occasionally, an ergonomic assessment is requested before any problems occur at all. The supervisor may explain that the employer is just trying to be proactive. In either case, this brief encounter with the supervisor will give an observant occupational therapist evaluator a very good feel for the organization's management culture and organizational priorities.

Following the supervisor interview, the occupational therapist evaluator will want to see the work area and meet the employees. The supervisor may give the evaluator a brief tour of the work area and describe the job tasks and methods that occur there. If the supervisor has identified any problem areas (areas that the supervisor thinks are contributing to injury), the supervisor should be encouraged to point these out. This part of the evaluation will give the evaluator an understanding of how management views the situation. Next, the evaluator will ask to meet with the workers.

Once alone with the worker(s) it is important to establish some level of trust. The evaluator will explain to the workers(s) why the organization has asked for an ergonomic evaluation. It should be explained that the purpose of the evaluation is to make the job safer and more comfortable for the worker(s). The worker(s) should be encouraged to give the evaluator a tour of the work area and to explain their job tasks. If there are any discrepancies between management's understanding of the job situation and the workers' understanding of the same, the evaluator must seek definitive clarification.

Finally, the worker(s) should be asked to begin performing the job as normally as possible. The evaluator will explain that he/she will be watching and perhaps videotaping or taking notes. The evaluator should assure the worker(s) that the information that is being recorded will be used to develop strategies to make the job tasks safer and more comfortable to perform. The evaluator must stress that he or she wants the workers(s) to do the job just like

any other day. The evaluator will not begin analysis of the work methods until at least 10 minutes has elapsed to allow the workers time to fall into a more normal work pattern.

The ergonomic workstation and work methods assessment should focus on identifying known risk factors for MSD. It is often very useful to videotape the work area and work methods performed. Recording the worker(s) performing their job tasks will allow the evaluator to return to his or her office and further analyze the data. If the evaluator plans to videotape any work areas or work methods, he or she should ask permission from the company before taping. It is becoming increasingly more difficult to gain permission for in-house videotaping because of confidentiality and trade secrets concerns. However, some companies are still willing to allow videotaping for the purpose of ergonomic evaluation. Always obtain prior written permission allowing you to videotape in-house. [Box 14-5](#) suggests a protocol for videotaping jobs for the purpose of ergonomic evaluation.

■ Box 14-5

Protocol for Videotaping Jobs for Ergonomic Evaluation

The following is a guide for preparing a videotape and related task information to facilitate job analysis and assessment of risk factors for work-related musculoskeletal disorders.

Materials Needed

- Video camera and blank tapes
- Spare batteries (at least 2) and battery charger
- Clipboard, pens, paper, blank checklists
- Stopwatch, strain gauge (optional) for weighing objects

Videotaping Procedures

1. To verify the accuracy of the video camera to record in real time, videotape a worker or job with a stopwatch running in the field of view for at least 1 minute. Playback of the tape should correspond to the elapsed time on the stopwatch.
2. Announce the name of the job on the voice channel of the video camera before taping any job. Restrict running time comments to the facts. Make no editorial comments.
3. Tape each job long enough to observe all aspects of the task. Tape 5 to 10 minutes for all jobs, including at least 10 complete cycles. Fewer cycles may be needed if all aspects of the job are recorded at least 3 to 4 times.
4. Hold the camera still with a tripod if available. Do not walk unless absolutely necessary.
5. Begin taping each task with a whole-body shot of the worker. Include the seat/chair and the surface that the worker is standing on. Hold this shot for 2 to 3 cycles and then zoom in on the hands/arms or other body parts that may be under stress because of the job task.
6. It is best to tape several workers to determine whether workers of varying body size adopt different postures or are affected in other ways. If possible, try to tape the best- and worst-case situations in terms of worker fit to the job.

The following suspected upper body problems suggest focusing on the parts indicated:

- Wrist problems/complaints
- Hands/wrists/forearms
- Elbow problems/complaints
- Arms/elbows
- Shoulder problems/complaints
- Arms/shoulders

For back and lower limb problems, the focus would be on movements of the trunk of the body and the leg, knee, and foot areas under stress as a result of task loads or other requirements.

7. Tape from whatever angles are needed to capture the body part(s) under stress.
8. Briefly tape the jobs performed before and after the one under actual study to see how the targeted job fits into the total department process.
9. For each taped task, obtain the following information to the maximum extent possible:
 - Whether the task is continuous or sporadic
 - Whether the worker performs the work for the entire shift or whether there is rotation with other workers
 - Measures of work surface heights and chair heights and whether adjustable
 - Weight, size, and shape of handles and textures for tools in use; indications of vibration in power tool use
 - Use of hand wear
 - Weight of objects lifted, pushed, pulled, or carried
 - Nature of the environment in which the work is performed (too cold or too hot?)

In light of these concerns, it may be helpful to develop an ergonomic checklist to assist in performing the on-site evaluation. The checklist should include the most common ergonomic risk factors and be tailored to the specific needs and conditions of the workplace that the occupational

therapist intends to evaluate. Figure 14-10 is an example of a typical ergonomic risk factor identification checklist. Figure 14-11 is an example of a checklist for computer workstation evaluation. Figure 14-12 is a typical hand tool risk factor checklist.

General Ergonomic Risk Analysis Checklist

Check the box if your answer is "yes" to the question. A "yes" response indicates that an ergonomic risk factor that requires further analysis may be present.

Manual Material Handling

- Is there lifting of loads, tools, or parts?
- Is there lowering of loads, tools, or parts?
- Is there overhead reaching for loads, tools, or parts?
- Is there bending at the waist to handle loads, tools, or parts?
- Is there twisting at the waist to handle loads, tools, or parts?

Physical Energy Demands

- Do tools and parts weigh more than 10 lbs?
- Is reaching greater than 20 inches?
- Is bending, stooping, or squatting a primary task activity?
- Is lifting or lowering loads a primary task activity?
- Is walking or carrying loads a primary task activity?
- Is stair or ladder climbing with loads a primary task activity?
- Is pushing or pulling loads a primary task activity?
- Is reaching overhead a primary task activity?
- Do any of the above tasks require five or more complete work cycles to be done within a minute?
- Do workers complain that rest breaks and fatigue allowances are insufficient?

Other Musculoskeletal Demands

- Do manual jobs require frequent, repetitive motions?
- Do work postures require frequent bending of the neck, shoulder, elbow, wrist, or finger joints?
- For seated work, do reaches for tools and materials exceed 15 inches from the worker's position?
- Is the worker unable to change his or her position often?
- Does the work involve forceful, quick, or sudden motions?
- Does the work involve shock or rapid buildup of forces?
- Is finger-pinch gripping used?
- Do job postures involve sustained muscle contraction of any limb?

Computer Workstation

- Do operators use computer workstations for more than 4 hours a day?
- Are there complaints of discomfort from those working at these stations?
- Is the chair or desk nonadjustable?
- Is the display monitor, keyboard, or document holder nonadjustable?
- Does lighting cause glare or make the monitor screen hard to read?
- Is the room temperature too hot or too cold?
- Is there irritating vibration or noise?

Environment

- Is the temperature too hot or too cold?
- Are the worker's hands exposed to temperatures less than 70° F?
- Is the workplace poorly lit?
- Is there glare?
- Is there excessive noise that is annoying, distracting, or producing hearing loss?
- Is there upper extremity or whole body vibration?
- Is air circulation too high or too low?

General Workplace

- Are walkways uneven, slippery, or obstructed?
- Is housekeeping poor?
- Is there inadequate clearance or accessibility for performing tasks?
- Are stairs cluttered or lacking railings?
- Is proper footwear worn?

FIGURE 14-10 General ergonomic risk analysis checklist.

(From Cohen AL, Gjessing CC, fine LJ, Bernard BP, McGlothlin JD: *Elements of ergonomics programs: a primer based on workplace evaluations of musculoskeletal disorders*, Washington, DC, 1997, US Government Printing Office.)

Continued

Tools

- Is the handle too small or too large?
- Does the handle shape cause the operator to bend the wrist in order to use the tool?
- Is the tool hard to access?
- Does the tool weigh more than 9 pounds?
- Does the tool vibrate excessively?
- Does the tool cause excessive kickback to the operator?
- Does the tool become too hot or too cold?

Gloves

- Do the gloves require the worker to use more force when performing job tasks?
- Do the gloves provide inadequate protection?
- Do the gloves present a hazard of catch points on the tool or in the workplace?

Administration

- Is there little worker control over the work process?
- Is the task highly repetitive and monotonous?
- Does the job involve critical tasks with high accountability and little or no tolerance for error?
- Are work hours and breaks poorly organized?

FIGURE 14-10, cont'd

■ **TABLE 14-4 | High-Risk Repetition Rates for the Upper Extremity**

Body Part	Repetitions per Minute
Shoulder	More than 2½
Upper part of arm/elbow	More than 10
Forearm/wrist	More than 10
Finger	More than 200

From Kilbom A: Repetitive work of the upper extremity; Part II: the scientific basis for the guide, *Int J Ind Erg* 14:59, 1994.

Risk factors to look for include the following:

1. Forceful exertions: Heavy lifting, pushing, pulling, twisting, gripping, or pinching. Handling heavy tools, equipment, or products. Difficulty maintaining control of equipment or tools or lifting and moving an object of asymmetric size. Also using inappropriate or inadequate tools.
2. Repetition: Performing the same motion or series of motions continually or frequently for an extended period (Table 14-4).
3. Awkward or static posturing, either repetitively or for prolonged periods: Assuming positions that place stress on the body, such as reaching above shoulder height, kneeling, squatting, leaning over a work surface, using a knife or keyboard with the wrists bent, twisting the torso while lifting, or looking at a computer monitor off to one side, which causes the neck to twist all day. Also, sitting all day at a desk with poor posture.
4. Contact stress: Pressing the body or part of the body (such as a hand or forearm) against hard or sharp

surfaces and edges (e.g., using the hand as a hammer, resting the forearms on a sharp desk edge while typing, and using pliers with the handle pressing into the palm).

5. Excessive vibration: For example, from power tools or sitting in a truck cab all day while driving.
6. Cold temperatures: Either working in cold temperature or handling cold tools or products (e.g., construction workers outside during winter handling metal tools and equipment or meat packers or butchers handling frozen meat).

Once the workstation and work methods risk factors have been identified and the worker(s) have had a chance to familiarize themselves with the occupational therapist, focus should turn to the psychosocial aspects of the job. Frequently, these factors will surface during the evaluation process without any prompting whatsoever. Factors such as workload and productivity stressors, quality of the relationship between the worker(s) and other coworkers and the supervisor, genuine job task enjoyment, and overall health and fitness cannot be overlooked. Work-related musculo-skeletal injury is never the result of any one factor; rather, it is the accumulation of a variety of risk factors and situations that ultimately result in injury. Occupational therapists look at the entire occupational profile to determine what is occurring.

Finally, it is important to ask the workers for their perspective on problem areas or risk factors in their work area. If their perspective matches what has been identified in the ergonomic evaluation of the work area and work methods, the workers should be encouraged to share their ideas for correcting the problem. Although the occupational therapist is the expert in workstation and work methods analysis, the on-site workers know their job better than anyone. The workers have probably spent hours formulating and discussing how they would change things if ever given the chance.

Risk Analysis Checklist for Computer-User Workstations

“No” responses indicate potential problem areas which should receive further investigation.

1. Does the workstation ensure proper worker posture, such as
 - horizontal thighs? Yes No
 - vertical lower legs? Yes No
 - feet flat on floor or footrest? Yes No
 - neutral wrists? Yes No
2. Does the chair
 - adjust easily? Yes No
 - have a padded seat with a rounded front? Yes No
 - have an adjustable backrest? Yes No
 - provide lumbar support? Yes No
 - have casters? Yes No
3. Are the height and tilt of the work surface on which the keyboard is located adjustable? Yes No
4. Is the keyboard detachable? Yes No
5. Do keying actions require minimal force? Yes No
6. Is there an adjustable document holder? Yes No
7. Are arm rests provided where needed? Yes No
8. Are glare and reflections avoided? Yes No
9. Does the monitor have brightness and contrast controls? Yes No
10. Do the operators judge the distance between eyes and work to be satisfactory for their viewing needs? Yes No
11. Is there sufficient space for knees and feet? Yes No
12. Can the workstation be used for either right- or left-handed activity? Yes No
13. Are adequate rest breaks provided for task demands? Yes No
14. Are high stroke rates avoided by
 - job rotation? Yes No
 - self-pacing? Yes No
 - adjusting the job to the skill of the worker? Yes No
15. Are employees trained in
 - proper postures? Yes No
 - proper work methods? Yes No
 - when and how to adjust their workstations? Yes No
 - how to seek assistance for their concerns? Yes No

FIGURE 14-11 Risk analysis checklist for computer workstations.

(From Cohen AL, Gjessing CC, fine LJ, Bernard BP, McGlothlin JD: *Elements of ergonomics programs: a primer based on workplace evaluations of musculoskeletal disorders*, Washington, DC, 1997, US Government Printing Office.)

Handtool Risk Factor Checklist

“No” responses indicate potential problem areas which should receive further investigation.

1. Are tools selected to limit or minimize
 - exposure to excessive vibration? Yes No
 - use of excessive force? Yes No
 - bending or twisting the wrist? Yes No
 - finger pinch grip? Yes No
 - problems associated with trigger finger? Yes No
2. Are tools powered where necessary and feasible? Yes No
3. Are tools evenly balanced? Yes No
4. Are heavy tools suspended or counterbalanced in ways to facilitate use? Yes No
5. Does the tool allow adequate visibility of the work? Yes No
6. Does the tool grip/handle prevent slipping during use? Yes No
7. Are tools equipped with handles of textured, non-conductive material? Yes No
8. Are different handle sizes available to fit a wide range of hand sizes? Yes No
9. Is the tool handle designed not to dig in the palm of the hand? Yes No
10. Can the tool be used safely with gloves? Yes No
11. Can the tool be used by either hand? Yes No
12. Is there a preventative maintenance program to keep tools operating as designed? Yes No
13. Have employees been trained
 - in the proper use of tools? Yes No
 - when and how to report problems with tools? Yes No
 - in proper tool maintenance? Yes No

FIGURE 14-12 Hand tool risk factor checklist.

(From Cohen AL, Gjessing CC, fine LJ, Bernard BP, McGlothlin JD: *Elements of ergonomics programs: a primer based on workplace evaluations of musculoskeletal disorders*, Washington, DC, 1997, US Government Printing Office.)

Ask them. Often, one will find a wealth of knowledge and many useful ideas for reducing or eliminating risk factors in the people who perform the job. It is important to exercise caution before using each suggestion. As the expert, it is the occupational therapist's responsibility to ensure that the changes implemented will serve to reduce and prevent

injury. Sometimes, worker-driven suggestions inadvertently cause new problems if not assessed appropriately by the ergonomic consultant.

Following the on-site evaluation, the occupational therapist returns to his or her office to analyze the data and prepare a report. The report will be shared with whomever

TABLE 14-5 | Combating Ergonomic Risk Factors

Risk Factor	Suggestions for Improvement
Using Excessive Force	Reduce Force Required to Perform Activity
Occupational therapist lifts/transfers heavy clients several times daily	Use Hoyer lift or get help from coworker
Employee uses heavy drill in a manufacturing plant	Suspend tools from ceiling with tension wire
Chef has difficulty cutting chicken in restaurant kitchen	Provide equipment to sharpen knives after every shift
Repetition	Reduce Prolonged Exposure to Repetitive Activity
Multiple scans required to activate grocery scanner	Implement program for regular preventive maintenance on scanners
Executive secretary required to type 5 hours in an 8-hour workday	Alternate typing task every 30 minutes with other office tasks such as making phone calls and filing
Awkward/Static Posturing	Reduce or Eliminate Awkward/Static Posturing
Medical transcriptionist types with her head turned to the right to see computer screen	Move computer monitor on desk so that it is directly in line with the computer keyboard and worker's face as she looks straight ahead
Same medical transcriptionist sits in same position all day to type	Require worker to stand and gently march in place for 60 seconds after every 30 minutes of typing; provide timer to remind worker
Grocery store checkout clerk bends at waist and grabs case of soda from bottom of cart with right hand several times daily	Teach body mechanics for proper lift technique and use of two-hand power grip
Contact Stress	Reduce or Eliminate Contact Stress
Typist rests her forearms on sharp desk edge to type	Provide soft wrist rest until budget allows purchase of new desk with rounded edges
Jewelry maker uses pliers with short handle to twist wires; end of handle rests in palm of hand	Provide pliers with longer handle that is gently curved to fit hand
Teacher uses side of fist to punch stapler several times daily	Provide electric stapler
Excessive Vibration	Reduce Vibration
Drill vibrates in hand of assembly line worker in manufacturing plant	Wrap handle of power tool in vibration-dampening tape and have the worker wear antivibration gloves that fit correctly (to avoid grasping tighter than necessary to handle tool)
Cold Temperature	Reduce Exposure to Cold
Construction workers outside in winter handle cold metal equipment and tools	Wrap tool and equipment handles with neoprene and provide workers with thermal gloves to wear; make sure that gloves fit the workers correctly to avoid grasping objects tighter than necessary
Meat and deli team at grocery store handle frozen foods frequently	Provide well-fitting thermal gloves to wear when handling frozen items and provide grasping tool to use for handling smaller frozen packages

requested the ergonomic evaluation. The report should contain an introduction explaining the background and purpose of the ergonomic evaluation, a description of the actual work area and work methods assessment, and finally the evaluator's findings and recommendations with clear and comprehensive information regarding how to implement the recommendations and resources for securing and

purchasing any equipment or services. Job tasks found to contain several risk factors for the development of WSMD have the greatest risk for injury and should be addressed first by the company. Recommendations will focus on ways to eliminate or reduce risk factors (Table 14-5).

Lorna benefited from a worksite evaluation. The occupational therapist went to her worksite to observe her and

the other workers perform some of the essential functions of the job in their actual work environment. Risk factors were identified, such as excessive force from pinching and pulling the fabric tightly over the padded wooden frame and from using the heavy staple gun. A significant amount of force is required to push the heavy furniture to the next workstation. Her work tasks are repetitive, for example, pulling the trigger of the staple gun and pushing and pulling the fabric and furniture all day long. Lorna and the other workers were observed to have awkward posturing with frequent bending, twisting, and squatting to move the bulky furniture around to staple the fabric down.

Lorna's employer was open to the suggestions that the occupational therapist made and was willing to make the appropriate accommodations. A special tool with a padded and curved handle to fit the shape of most hands was purchased to allow the workers to use a grasp-release motion to activate a material clamp rather than using the fingers so forcefully to pinch and pull the fabric. To lessen the amount of bending, twisting, and squatting required, it was recommended that the company purchase commercially available platforms on wheels to easily move the wooden furniture frames around. Additionally, the platforms contain a simple hydraulic lift that elevates the frame to whatever height is needed for easy stapling. The occupational therapist researched and located a resource for purchase of this helpful equipment, which facilitated the employer's timely implementation of the worksite recommendations. Worksite evaluations and ergonomic interventions can also be important aspects of a comprehensive injury prevention program, as discussed in the next section.

Injury Prevention Programs

For decades, the majority of occupational therapy practice has been in the area of rehabilitation. Occupational therapists are unquestionably skilled in facilitating client independence during and/or following an injury, illness, or disease. Though not an entirely new concept, we are now recognizing occupational therapy's potential to facilitate and perpetuate independence before or even in avoidance of these events. As we move into the 21st century, increasing numbers of occupational therapists are broadening their practices to include wellness and prevention.

Support for this movement is ubiquitous. The 1994-1996 landmark University of Southern California's Well Elderly Study supports occupational therapy's preventive intervention role in enhancing physical and mental health, occupational functioning, and life satisfaction.⁴⁰ The *Occupational Therapy Practice Framework: Domain and Process*, second edition, provides further support and lists health promotion, performance maintenance, and disability prevention as occupational therapy intervention approaches that facilitate "participation in life through engagement in occupations."⁴¹ Finally, in 2004, AOTA President Carolyn Baum, PhD, OTR/L, FAOTA, identified several

prevention-related businesses as "hot" occupational therapy emerging practice areas.⁵⁷

With regard to occupational therapy and work, prevention can take on three forms: primary prevention, secondary prevention, and tertiary prevention. Primary prevention efforts help protect healthy workers against a targeted condition before the condition occurs. Interventions are directed to an entire workforce to prevent a specific work-related medical problem. Secondary prevention emphasizes early identification of and intervention for asymptomatic workers who have risk factors for the development of work-related medical problems, as well as identification and treatment of workers with mild medical symptoms in the early reversible stages of injury. The goal is to identify risk factors so that they can be minimized or eliminated and to reverse any medical problems that might be developing. Tertiary prevention occurs after a worker suffers nonreversible injury, illness, or disease. Interventions include treatment of the medical problem, attempts to restore maximum function in the workplace, and prevention of injury, illness, or disease-related complications. The goal is to return the affected worker to gainful employment within the confines of the medical problem and to prevent further injury. Once a permanent work-related injury occurs, primary and secondary prevention measures have failed. However, early risk factor detection and intervention through secondary prevention may have minimized the severity of the permanent injury.^{85,99}

Most occupational therapists are familiar with the process of tertiary prevention of work-related medical problems. Typically, the occupational therapist becomes involved after a worker suffers an injury and it becomes the therapist's job to help the client regain maximum function in the workplace and prevent further injury. Occupational therapists are also commonly involved in secondary prevention efforts. Workers are referred with mild work-related medical conditions and intervention is planned to reverse the symptoms. When these clients get ready to return to work, the occupational therapist may assist the client in identification and modification of risk factors to reduce the risk for reinjury. Worksite evaluation and ergonomic intervention are generally part of the process for successfully re-engaging these workers.

Worksite evaluation and ergonomic intervention can also be part of a comprehensive primary prevention program designed to prevent work-related injury, illness, and disease.

Helping employers improve worker fitness, job comfort, and workplace safety reduces work-related medical problems. It can also lead to improved employee morale and increased productivity.³⁹ Occupational therapists, acting as consultants, can assist corporate clients in establishing injury prevention programs. This is one way that occupational therapists can incorporate the concepts of wellness and health promotion into their daily practices.

Occupational therapist Michael Melnick wrote that "the success or failure of a prevention program has less to do

with specific activities implemented and more to do with the methods of implementation.⁶⁰ Melnick outlines the four characteristics that are common among successful injury prevention programs: ongoing management support, supervisor “buy in,” employee participation, and ongoing support and reinforcement.⁶⁰ Melnick explains that successful prevention programs are grounded in the consultant’s ability to instill in the corporate client a culture of safety and wellness. The focus should be on the process of implementing safety and wellness activities and not on the activities themselves.

One common reason that an occupational therapist might be asked to consult with an industrial client is to control the severity and incidence of WMSDs. WMSDs are a class of soft injuries affecting the muscles, tendons, and nerves. Other names for WMSDs are cumulative trauma disorders, overuse syndromes, and repetitive strain disorders. WMSDs come on slowly and develop over time. They are thought to be the result of repeated microtrauma to a body and occur when the body is denied the opportunity to adequately rest and repair itself. Common diagnoses within the class of WMSDs include carpal tunnel syndrome, de Quervain tendinitis, lateral epicondylitis, and some types of back injuries.⁸¹

According to the Bureau of Labor Statistics, WMSDs accounted for 29% of all workplace injuries requiring time away from work in 2007 (reference page info: retrieved from the Bureau of Labor Statistics—www.bls.gov/opub/ted/2008/dec/wk1/art02.htm-on September 27, 2010). Employers pay more than \$45 billion annually in worker’s compensation and other expenses associated with these disorders.⁴ These statistics indicate that WMSDs are at a crisis level in the workplace. However, the financial losses to industry and the economy pale in comparison to the physical and emotional pain and suffering endured by today’s injured workers.

Lorna and several of her coworkers were experiencing WMSDs. Their employer agreed to implement an in-house ergonomics program and injury prevention program at the recommendation of the occupational therapy consultant. An ergonomic team was developed that consisted of the company’s chief financial officer, the stapling station supervisor, the employee health nurse, the safety manager, the occupational therapist consultant, and three employees who worked in the stapling station, including Lorna.

There are a multitude of resources available for prevention consultants interested in helping corporate clients develop effective programs for evaluating and addressing musculoskeletal concerns in the workplace. OSHA and NIOSH are excellent starting points. [Box 14-6](#) offers information on these two government entities and provides a partial listing of their ergonomic and injury prevention resource materials.

It is important to remember that every corporate client is unique and that the consultant’s recommendations must

work within the corporate culture, goals, and budget constraints. Melnick also reminds us that we must help our corporate clients recognize that “injury prevention consultants do not reduce injuries. This would occur only if the consultant stepped in and performed each worker’s job. Rather, prevention consultants help companies reduce their losses by guiding them through various activities.”⁶⁰

As a guiding framework, however, the injury prevention consultant will want to incorporate the following elements into the corporate plan:

- A process for the organization to initially identify the potential risk for musculoskeletal problems or other risk factors in the workplace
- A strategy for showcasing management’s commitment to addressing problems and encouraging open worker involvement in problem-solving activities
- Skill training to ensure that management and workers can evaluate work areas and work methods for risk factors that could lead to musculoskeletal problems
- Protocols for gathering data to identify jobs or work conditions that are most problematic and at-risk by using strategies such as ergonomic evaluation
- A strategy for developing effective controls for identified risk factors that if left untouched, could lead to musculoskeletal injury
- Protocols for outcomes assessment to see whether the musculoskeletal injury risk factor controls have actually reduced or eliminated the problem
- A plan for establishing a health care management program that emphasizes the importance of early detection and treatment of MSDs since early identification and treatment of these disorders almost always reduce the severity of injury and disability and their associated costs
- A plan for minimizing future risk factors for musculoskeletal injury when new work processes and work areas are in development since it is less costly to build good design into the workplace than it is to redesign or retrofit later

The essential elements of musculoskeletal injury prevention programs listed above are based on recommendations from both OSHA and NIOSH.^{14,68-71} In the 1990s and early 2000s, these two entities developed guidelines and recommendations for public and private sector organizations seeking to establish in-house musculoskeletal injury prevention programs. These informational documents are available through OSHA and NIOSH and are an invaluable resource for occupational therapists wanting to offer prevention consulting services to address WMSDs.

Empowering Corporate Clients: The Injury Prevention Team

Corporate clients initially realize they may have a problem with WMSDs in a variety of ways. Signs of potential problems include worker reports of frequent aches and pains via

Box 14-6

OSHA and NIOSH

The Occupational Safety and Health Act of 1970 created both the National Institute for Occupational Safety and Health (NIOSH) and the Occupational Safety and Health Administration (OSHA). Although NIOSH and OSHA were created by the same act of Congress, they are two distinct agencies with separate responsibilities.

OSHA is in the U.S. Department of Labor and, as a regulatory agency, is responsible for developing and enforcing workplace safety and health regulations. OSHA developed the following publication guidelines to assist industries in developing in-house ergonomic programs:

- Ergonomic Program Management Guidelines for Meatpacking Plants (1993) (OSHA Publication 3123)
- Guidelines for Nursing Homes: Ergonomics for the Prevention of Musculoskeletal Disorders (Revised 2009) (OSHA Publication 3182)
- Guidelines for Retail Grocery Stores: Ergonomics for the Prevention of Musculoskeletal Disorders (2004) (OSHA Publication 3192-05N)
- Guidelines for Poultry Processing: Ergonomics for the Prevention of Musculoskeletal Disorders (2004) (OSHA Publication 3213-09N)
- Guidelines for Shipyards: Ergonomics for the Prevention of Musculoskeletal Disorders (2008) (OSHA Publication 3341-03N)

These publications can be ordered at www.osha.gov or by calling 1-800-321-OSHA.

NIOSH is part of the Centers for Disease Control and Prevention (CDC) within the U.S. Department of Health and Human Services. NIOSH is an agency established to conduct

research and make recommendations for preventing work-related injury and illness. NIOSH and OSHA often work together toward the common goal of protecting worker safety and health. NIOSH currently offers several publications to assist in ergonomic intervention efforts. The following may be of interest to occupational therapy practitioners wanting to get involved in ergonomics:

- Elements of Ergonomic Programs: A Primer Based on Workplace Evaluations of Musculoskeletal Disorders (1997) (NIOSH Publication 97-117)
- Simple Solutions: Ergonomics for Construction Workers (2007) (NIOSH Publication 2007-122)
- Ergonomic Guidelines for Manual Material Handling (2007) (NIOSH Publication 2007-131)
- Safe Lifting and Movement of Nursing Home Residents (2006) (NIOSH Publication 2006-117)
- Conference Proceedings: Prevention of Musculoskeletal Disorders for Children and Adolescents Working in Agriculture (2004) (NIOSH Publication 2004-119)
- Easy Ergonomics: A Guide to Selecting Non-Powered Hand Tools (2004) (NIOSH Publication 2004-164)
- Simple Solutions: Ergonomics for Farm Workers (2001) (NIOSH Publication 2001-111)
- Ergonomic Interventions for the Soft Drink Beverage Delivery Industry (1996) (NIOSH Publication 96-109)

These publications (and others) can be ordered from the CDC-NIOSH website <http://www.cdc.gov/niosh>; NIOSH at 1-800-CDC-INFO (1-800-232-4636), outside the USA at 513-533-8328.

employee health visits or organized symptom surveys, injury and illness trends among workers performing the same job tasks, and identification of injury risk factors as a result of preventive ergonomic job analysis.¹⁴ Figure 14-13 presents an example of a typical symptom survey used by companies to screen for potential work-related musculoskeletal problems. Once an organization recognizes that it has a problem with WMSDs, it must develop a strategy to address the problem. At this point, corporate clients frequently seek an injury prevention consultant to “make the problem go away.”

Corporate clients frequently seek injury prevention specialists in the hope of achieving a quick and definitive fix. However, controlling WMSDs needs to be an ongoing process of control and management. The injury prevention consultant must work toward empowering the corporate client to maintain a successful injury prevention program consistently over time. The consultant must ensure that the client company has the knowledge and skills to follow through with the program. The role of the injury prevention consultant is to help the organization put together a

team and a strategy for ongoing identification and control of risk factors for musculoskeletal injury.

In the same way that occupational therapists teach individuals to be self-sufficient in performing activities of daily living, they can also teach their corporate clients to be self-sufficient in controlling risk factors for musculoskeletal injury in the work environment. This client-centered approach has occupational therapy intervention focused on the corporate client's priority of controlling work-related injuries and their associated costs. The occupational therapy intervention plan is the development of a corporate in-house injury prevention team. Another name for this team is the ergonomics team.

Usually, the injury prevention consultant will decide with corporate management who will be a part of the ergonomics team. Ideally, the team will be composed of representatives from management, front-line supervisors, production workers, labor unions, employee health, safety and/or industrial hygiene, engineering, and the injury prevention/ergonomic consultant. The exact makeup of the team will vary depending on the nature of the organization

Symptoms Survey: Ergonomics Program

Date ____/____/____

Plant _____ Dept # _____ Job Name _____

Shift _____ Hours worked/week _____ years _____ months
Time on THIS Job

Other jobs you have done in the last year (for more than 2 weeks)

Plant _____ Dept # _____ Job Name _____ months _____ weeks
Time on THIS Job

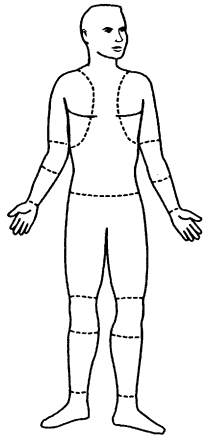

Plant _____ Dept # _____ Job Name _____ months _____ weeks
Time on THIS Job

(If more than 2 jobs, include those you worked on the most)

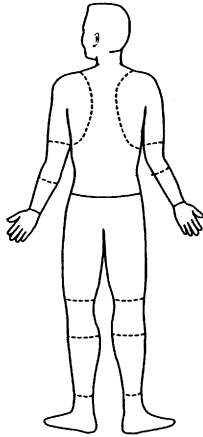

Have you had any pain or discomfort during the last year?

Yes No (If NO, stop here)

If YES, carefully shade in area of the drawing which bothers you the MOST.

Front

Back

(Continued)

FIGURE 14-13 Symptom surveys are sometimes used as screening tools in companies that suspect problems with work-related musculoskeletal disorders. Workers are asked to voluntarily fill out the survey. The surveys are analyzed for trends indicating similar musculoskeletal symptoms within certain work groups. If workers from a specific work group tend to have similar complaints, the job tasks and workstations should be analyzed further.

and corporate structure. The team meets and formulates a strategy for developing and implementing the injury prevention program.

Initial meetings will typically focus on the nature and scope of reported injuries and the effects that these injuries have had on production, worker's compensation and associated costs, employee retention, and employee morale. An analysis of existing medical, safety, and insurance records can be conducted for the purpose of identifying injuries associated with MSDs. Health care team members should be encouraged to present medical record and injury information in a way that protects the confidentiality of individual workers. The team can then determine incidence rates of MSDs and look at trends that indicate problem work areas or job tasks.

Once the scope of the problem has been analyzed, the team will decide on a plan of attack for prevention of injury. In general, the magnitude and location of existing problems will suggest the magnitude and direction of the initial team efforts. The consultant will want to direct the corporate client to address the most grievous and resource-draining problems first. If on analysis of the data the problems seem widespread and involve a large percentage of the workforce, the plan of attack will probably be an aggressive company-wide program. On the other hand, if the problems seem to be isolated to just a few work areas or employees, the initial plan would probably be more focused and direct.¹⁴

Management Commitment

The industrial safety and health literature stresses that support of management in injury prevention efforts is crucial for successful implementation and outcomes.¹⁴ The consultant will want to ensure that management commitment to the process is genuine. If there is a lack of sincere top-level support for the injury prevention program, a consultant would be wise to pass on his or her involvement. Consultants are judged on their record of success. Prevention efforts without management support are destined to fail.

A good injury prevention consultant knows that employees want to see evidence of management support for all new programs. One of several ways to assist corporate clients in demonstrating support to the workforce is to encourage management to issue policy statements that give injury prevention efforts equal priority with productivity standards and cost control. Management should also meet with employee or union representatives (who should ideally be part of the ergonomics team) to discuss new policy and injury prevention program plans and show evidence of committing resources to implement the injury prevention program. Goals should be set and timelines established for meeting these goals, with specific people assigned responsibility and held accountable for overseeing various aspects of the program. Finally, information about the program should be disseminated to the entire workforce, from planning, to

implementation, to evaluation. Employees want and need to feel that they are a part of the organization's commitment to safety.^{10,14}

Training in Risk Factor Identification/Ergonomic Evaluation and Problem Solving

Research has identified specific physical activity demands that place people at risk for the development of WMSDs: repetition, force, awkward or static posturing, prolonged direct pressure on soft tissue, vibration, exposure to cold, and inappropriate or inadequate hand tools.^{14,68-71,81} Additionally, psychosocial stressors at work can contribute to the development of WMSDs.¹⁴ Although this is an area in need of further study, these types of stressors can include excessive volume or productivity expectations, work that is "too difficult" or beyond the intellectual or emotional capacity of the employee, or a superior who does not express appreciation for a job well done. It is the combination of physical and psychosocial risk factors that the ergonomics team must address as part of an injury prevention program for WMSDs.

The ergonomics team will probably have the injury prevention consultant perform the first ergonomic evaluations at the workplace and present the first suggestions for improvement. However, key members of the injury prevention team should receive training in performing these evaluations themselves and training on how to formulate solutions. In this way, the evaluation part of the process is not reliant on an outside source. The goal, eventually, is to have the injury prevention consultant step out of the picture and leave behind a self-sufficient team of in-house experts to implement an ongoing process of risk factor identification for control of MSDs.

Figure 14-10 is an example of a general ergonomic injury risk analysis checklist. Members of the injury prevention team could be trained to use this tool to screen a variety of jobs for risk factors for musculoskeletal injury. Similarly, Figure 14-11 is an example of a job-specific screening tool. This checklist helps evaluators identify risk factors for musculoskeletal injury in computer users. Figure 14-12 is a hand tool analysis checklist. The injury prevention consultant or ergonomics team members could choose to modify any of these screening tools to match jobs specific to the organization.

The NIOSH publication "Elements for Ergonomics Programs 12" lists several objectives for team member training. A successfully trained team member will be able to do the following:

- Recognize risk factors for musculoskeletal injury and understand basic methods for their control
- Identify signs and symptoms of musculoskeletal injury in workers
- Understand the company's injury prevention program thoroughly and everyone's role and responsibility from top-level management to front-line worker

- Know the company's procedure for reporting identified risk factors and signs and symptoms of musculoskeletal injury
- Demonstrate the ability to perform a basic ergonomic evaluation for identifying risk factors for musculoskeletal injury
- Recommend ways to control injury risk factors based on collaboration with employees, management, and other members of the ergonomics team
- Select ways to implement and evaluate the control measures
- Demonstrate skill in team building, consensus development, and problem solving

Some companies will decide to extend training to other members of the workforce. General training can be provided to employees who may potentially be exposed to hazards for musculoskeletal injury. Training can include how to recognize and report early signs and symptoms of musculoskeletal injury, information on identifying risk factors for musculoskeletal injury both at work and outside work, and strategies for workers to protect themselves from the development of musculoskeletal injury. Supervisors should receive the same training as workers, as well as training in techniques to reinforce proper body mechanics and other important aspects of the injury prevention program.⁷¹

Training the ergonomics team in skills required to sustain the injury prevention program is a substantial aspect of the consultant's role. The consultant selects or designs the training and training materials to be understandable to the layperson in accordance with the participants' educational levels and literacy ability. Consideration of language skills is also important, and attempts should be made to provide materials in the primary language of the employee.¹⁴ Outside training courses are also valuable in bringing perspective to the organization's situation. Interaction with other companies' course attendees provides opportunities for company-to-company networking. Many resources exist for locating appropriate training courses, including NIOSH and OSHA.

Developing Risk Factor Controls

The ergonomic evaluations will identify known risk factors for the development of MSDs. Risk factors might include forceful exertions, awkward or static posturing, repetition, contact stressors, vibration, exposure to cold, and/or psychosocial stressors. These identified risk factors will be brought back to the ergonomics team for discussion. Once high-risk areas or tasks have been identified, the task of the team then becomes formulating ways to reduce or eliminate the risk factors for musculoskeletal injury.

At this point it is important to use as many front-line production workers in the problem-solving process as possible. Workers know their jobs better than anyone

and may have already formulated some ideas about improving the work area or work methods. Promoting worker involvement at this point has several benefits: enhanced worker motivation and job satisfaction, added team problem-solving capabilities, greater acceptance of workplace change, and greater knowledge of the work and organization.^{12,14,48,49,66}

When workers present ideas for risk factor modification, it is essential that the injury prevention consultant and the in-house ergonomics team ensure that these potential solutions are appropriate and do not carry with them any potential for creating new problems. Union representatives should ensure that the suggested solutions do not violate employee-management understandings and contracts. Engineering's role is to evaluate suggested solutions for practical and physical feasibility. Management's role is to provide input regarding the organizational and financial appropriateness of the suggested solutions.

There are a variety of ways to reduce or eliminate risk factors for musculoskeletal injury. The 1991 OSHA publication *Ergonomics Program Management Guidelines for Meatpacking Plants* outlines a variety of risk factor control strategies applicable to most any workplace situation. These strategies can be categorized as either engineering controls, work practice controls, administrative controls, or use of personal protective equipment.⁷¹

Engineering controls include strategies for designing or modifying the workstation, work methods, and/or tools. The goal is to eliminate or reduce excessive exertion, awkward postures, and repetition. Workstations should be designed or modified to accommodate the actual worker at that workstation. If more than one person uses a workstation, elements of the workstation should be adjustable to fit each worker and be comfortable for the workers to use. Work methods should be designed or modified to minimize static and awkward posturing, repetitive motions, and excessive force. Tools and handles should be designed for a specific job and minimize contact stress, vibration, and forceful motions/gripping by the workers' hands.⁷¹

Work practice controls include policies and procedures for safe and proper performance of tasks that are understood by all and enforced by supervisors. Workers should receive training in proper body mechanics, tool maintenance, and use of workstation adjustability features. New workers and those who have been away for awhile should be allowed adequate break-in periods to condition and recondition their bodies for the physical demands of the job. Supervisors and management should constantly monitor the use and effectiveness of work practice controls and make adjustments in techniques, line speed, and staffing as needed to maintain a safe and healthy work environment.⁷¹

Selection and use of personal protective equipment should be in line with the overall injury prevention program. Equipment should be available in a variety of sizes to accommodate the size differences among workers. Proper fit is especially important for gloves because improperly

fitting gloves can reduce blood flow and sensory feedback and lead to slippage and use of excessive grip and pinch force. Protection against extreme cold (<40° F) is required to protect joints and soft tissues. Back braces and upper extremity splints should not be considered personal protective equipment. These devices are part of the medical management aspect of the program and should be used only with the advice and under the supervision of the health care team.⁷¹

Finally, administrative controls must be an option in situations in which musculoskeletal risk factors cannot be adequately reduced or eliminated via engineering controls, work practice controls, and the use of personal protective equipment. Administrative controls reduce the duration, frequency, and severity of exposure to risk factors. Methods include decreasing production rates, limiting overtime work, providing periodic rest breaks throughout the day, increasing staffing levels, and using job rotation/job enlargement to other jobs and tasks that involve the use of different muscle-tendon groups.⁷¹

When the team comes to a consensus on which methods to use to reduce or eliminate the risk factors for musculoskeletal injury, it is time to formulate a plan and implement the proposed solutions. However, before any changes are made, it is important to again solicit employee feedback regarding these plans, especially from employees who are not involved in the ergonomics team. Most people are resistant to change; it is human nature. Soliciting and sincerely listening to feedback improve employee buy-in for the proposed changes. Additionally, this feedback might identify implementation problems that the ergonomics team overlooked. Even the best idea for improving the comfort and safety of a job cannot be successfully implemented without employee support. Performing this step in the process is well worth the time and effort.

Medical Management Strategies

In addition to identifying risk factors for musculoskeletal injury and implementing plans to reduce or eliminate these risk factors, it is important for the ergonomics team to develop a medical management plan. Initiating early conservative medical treatment is key to minimizing serious disorder and dysfunction.⁶³ Workers should be trained to identify early symptoms of MSDs so that they can seek medical care. The employee health staff should formulate guidelines for the management of employees with early symptoms of MSDs. This plan might include oral anti-inflammatories, splinting, rotation to light duty or time off work, and occupational therapy. The physician and/or employee health nurse will usually lead the effort in developing medical management guidelines for the organization.

As occupational therapists, it is important to understand the role and implications of upper extremity splinting of work-related injuries. The health care team should think

about the possible ramifications of prescribing an upper extremity splint to a worker who plans to remain on the job. It is true that splinting helps rest the injured body part and that this can be helpful for recovery from a musculoskeletal injury. However, when a worker is restricted from moving, for example, the wrist during work, the result is often that the elbow or shoulder will compensate by positioning itself awkwardly to get the task accomplished. Splinting during work may protect the wrist, but the result could be injury to the elbow, shoulder, neck, or back. Therefore, splints should not be used at work unless the health care team understands the worker's job tasks and can ensure that using the splint will not place stress on other parts of the body.

Outcomes Assessment and Preventing Future Problems

Finally, once the ergonomics team has implemented both efforts at controlling risk factors for musculoskeletal injury and the medical management process, the entire injury prevention program must be evaluated for effectiveness. Outcomes measures are useful in determining whether the program is working and to what extent. If the program does not seem to be working to any significant degree, the team will continue to modify its efforts until the incidence of WMSDs has declined to acceptable levels. The injury prevention program should be considered an ongoing process rather than a short-term solution to an identified incident or problem work area. Most ergonomics teams find that as soon as one problem work area is under control, another problem is identified that requires the focus of the team's efforts.

The occupational therapist is an invaluable resource for helping organizations develop in-house injury prevention programs to control risk factors related to the development of musculoskeletal injury. The occupational therapist's basic training in occupational performance analysis, problem identification, intervention planning and implementation, and outcomes assessment makes the fields of ergonomics and injury prevention ideally suited for practitioners of our profession. The NIOSH and OSHA are valuable resources for occupational therapists interested in working in ergonomics and injury prevention.

Pre-Employment Testing

A frequent use of functional testing includes assessing a person's ability to meet certain physical requirements before being hired for a job.⁷⁸ Some pre-employment testing may consist of isometric strength testing, ROM testing, or actual measurement of a person's ability to perform selected tasks from the job description. Pre-employment screening can be an integral part of a company's comprehensive injury prevention and management strategy.⁷⁸ Because of their

training in task analysis and holistic approach, occupational therapists are excellent candidates for assisting companies in expanding plans to more effectively manage employee injuries.

OT Practice Notes

Because of task analysis training and a holistic approach, occupational therapists are excellent candidates for assisting companies with expansion of plans to more effectively manage employee injuries.

When a company is looking at the overall impact of an employee injury on the bottom line, it goes much further than simply the cost associated with the injury itself. It extends beyond the medical costs to include the employee's compensation, benefit package payments, training of replacement personnel, replacement personnel wages, and overtime payment for existing personnel if they are needed for coverage. This does not include the indirect costs of diminished productivity during the period when coverage is being arranged. The total impact can be quite staggering. The cost of developing an employment screening process is significant; however, the cost savings to the company can be dramatic.⁷⁸

The EEOC's *Uniform Guidelines on Employee Selection Procedures* sets forth guidelines for the structure and function of human resource departments within companies and businesses. The guidelines also address how an organization can select and manage employees and places strong emphasis on the necessity of policies and procedures being job related.^{24,78} The EEOC also mandates that an employer's selection process not have adverse impact on any group of people and must not discriminate on the basis of race, color, religion, sex, or national origin, as established by Title VII of the Civil Rights Act of 1964.^{24,78} Meeting these criteria requires that the selection procedures demonstrate validation, be of business necessity, and be a bona fide occupational requirement.^{24,78} To be compliant with the ADA, pre-employment screening must be based on an accurate job description, test only the essential functions (although not every function need be assessed), and have high face validity (often referred to as content validity—tests what you really want to know) or closely mirror the aspects of the job that is being tested.^{6,78} Dynamic testing (actually replicating physical tasks from the job) is recommended and can be conducted on-site at the company or off-site and needs to use equipment from the job as it is available.⁷⁸ It is vital that companies take the time to thoroughly develop their screening process to be able to defend why the screening was considered necessary, maintain awareness and vigilance in the development phase of good test design, and be

prepared to explain and demonstrate the applicability of the screening to the job in question.⁷⁸

Pre-employment testing can also occur at several points in the hiring process; however, many health care providers and legal experts recommend conducting such testing after an offer of employment has been extended.^{31,54} With post-offer screening (POS), the most advantageous progression is to interview the applicant and determine whether the person is an acceptable candidate for employment.⁷⁸ A conditional offer is extended to the applicant based on the applicant's ability to meet a variety of conditions, such as passing a drug screen, acceptable background check, and physical testing. A problem with pre-offer testing is that Title 29 of the Code of Federal Regulations specifically states that medical examination is permissible "after making an offer of employment to a job applicant."¹³ Monitoring blood pressure or the heart rate or inquiring about past medical history is considered to be part of a medical examination and is precluded in pre-offer testing.⁷⁸

Anything that a therapist does in the way of evaluating an applicant might be deemed medical simply because an occupational therapist is a medical professional. It is also important to look critically at any testing that is considered to be general strength testing because it has been found to be a poor predictor of potential for injury.^{21,65,78} Normative databases are of little use in making hiring decisions, too, since according to both the ADA and the EEOC, it does not matter whether the applicant falls into the 5th percentile or the 95th percentile; the only thing of importance is whether the applicant can perform the tasks of the job.^{6,24}

If the applicant passes the screening, he or she is hired and begins working. If the applicant does not pass, the employer must assess whether the applicant has a disability as defined under the ADA (see [Chapter 15](#)).⁶ If the applicant does, the employer must determine whether reasonable accommodation can be offered to the applicant so that the individual may be able to perform the job. Reasonable accommodation means providing accommodation in such a way that the employer is not placed under undue financial strain for the accommodation to be implemented. If the company can and does offer accommodation to the applicant, the hiring process is completed and the employment begins. If the company cannot offer reasonable accommodation or if the applicant does not have a disability yet fails the screening, the employer can choose to rescind the offer of employment, examine opportunities for alternative placement elsewhere in the company, or offer remediation of some type and allow the applicant to retest if certain criteria are met.⁷⁸ For example, if a nondisabled applicant does not pass the lifting portion of a POS and otherwise meets the employment criteria, the company might elect to allow the applicant 2 weeks to improve strength with the goal of returning for a retest screen in an attempt to pass the lifting portion.

Suppose Henry (the roofer in the case study) had difficulty balancing on one leg as a result of an early childhood accident but that this balance problem was not something that was readily apparent. If a POS were conducted on Henry before being hired at the roofing company and balance was a component of testing for working as a roofer, his difficulty could have been detected and Henry could have been denied the job or offered alternative placement. Either way Henry would have been protected from a fall that would radically change his life.

A company does not have to test applicants for every job. Typically, it is suggested that a company survey all of its injuries and determine where the majority of injuries are occurring and if they are occurring within the first 6 months of hiring. If so, this company is a good candidate for implementing a physical screen as part of the hiring process. Once it is determined which jobs are going to be selected for testing, the physical demands of the job must be evaluated. This can be done by survey, questionnaire, or observation (either direct or video).⁷ The job description must include information that is functional in terms of physical demands, describe the essential tasks of the job, and be presented in such language that one can test for an individual's ability to perform them.⁷ In the case of a company requesting that existing job descriptions be used for development of the screen, it is extremely important to document that the company provided the job descriptions and that the therapist does not assume any liability for errors in their accuracy.

Physical demand items can then be selected for testing during screening based on either the difficulty or the frequency of the item. It is not necessary to test all of the physical demands for each job. For instance, a job might include carrying 10 lb a distance of 10 feet twice a day and lifting 40 lb from pallet height to waist height 200 times per day. Testing the ability to lift 40 lb would be a better selection for testing, for if the applicant is able to lift 40 lb from pallet height to waist height, it is likely that he or she will also be able to carry 10 lb a distance of 10 feet. It is important to select a method of testing the tasks that is reliable and valid and demonstrates job applicability, whether choosing from a standardized battery of physical demand tests or developing job-specific tasks to improve the applicant's understanding of the relevance of the task and defensibility of hiring decisions.^{24,78}

After tasks are selected, implementation can begin. It is suggested that a statistically significant sample of incumbents be tested to ensure that the correct demands have been selected and that the minimum requirements for each demand have been set appropriately. Once pilot testing is complete, the screening can be administered consistently to all applicants for a given job. It is also recommended that the screening process be monitored to ensure that fair and nondiscriminatory selection of applicants is occurring and that modifications in the screening process can occur as needed.⁷⁸

Ethical Considerations

It is imperative for the clinician to encourage companies to have written policies regarding the screening process, including how to handle screening failures.⁷⁸ It is also important to extricate the therapist from the hiring process in that all communications come from the employer so the therapist is allowed to maintain objectivity and third-party distance from the course of action.⁷⁸ Continuing documentation and follow-up help establish a definitive paper trail demonstrating the business necessity for implementing a pre-employment screening process, the steps taken to select and analyze the job and tasks to be tested, the implementation phase, ongoing quality assurance to monitor any changes in the job and reflect subsequent changes in the screening and the actions taken to handle screening failures, reasonable accommodation, and avoidance of adverse impact.⁷⁸

Transition Services from School to Work

Occupational therapy practitioners can make a valuable contribution to students with disabilities who are transitioning from school to the community. The 1997 amendments to the Individuals with Disabilities Education Act (IDEA) of 1990 specified that transition planning is to be part of the Individualized Education Program (IEP). Representatives from community agencies that provide post-school services, such as state-sponsored vocational rehabilitation, must join the education team. Related services such as occupational therapy are formal contributors to the transition planning for students who need these type of services.⁹⁴ Transition services are defined by the IDEA as “a coordinated set of activities for a student designed within an outcome-oriented process, which promotes movement from school to post-school activities, includes postsecondary education, vocational training, integrated employment (including supported employment), continuing and adult education, adult services, independent living, or community participation.”⁹³ Occupational therapy's unique focus on occupational performance can be a strong asset to the transition team.

The three main roles that an occupational therapist will participate in are transition-related evaluation, service planning, and service implementation. The occupational therapist contributes vital information about students' performance abilities and needs in any of the transition domains: domestic, vocational, school, recreational, and community.

Transition-Related Evaluation

Effective transition-related evaluation primarily uses non-standardized interviews, situational observation, and activity analysis approaches. These approaches are top-down,

which means that they first consider what the student wants or needs to do and secondarily identify the occupational performance issues that are causing difficulties.⁷ The transition team helps the student identify a positive, shared vision for the future. This can include living alone or with others in the community, attending post-secondary schools or training programs, working in a paid or volunteer job, using community services, and participating in activities of interest. The occupational therapist and other members of the team work together to identify the student's present interests and abilities within the context in which performance is expected or needed. The evaluation process also allows the team to identify areas in which the student is likely to need ongoing support and resources to achieve his or her vision and goals for the future.

Service Planning

In a collaborative transition team, the team members collectively share information and write down the student's goals.⁹⁴ The team members do not record discipline-specific goals that focus on remediating the student's underlying deficits. The occupational therapist, for example, does not need to write specific goals addressing cognitive, motor, or psychosocial skills. Instead, two or more group members gather together to write the goals and work collaboratively with the student to accomplish the goals. A student with limited movement in her arms and hands may have the goal of being able to complete written assignments. The occupational therapist may take the lead in evaluating the effectiveness of using alternative writing methods such as assistive technology. Recommendations are made to the student and the team. If the team supports the recommendations, the team would assign responsibility for obtaining the equipment, as well as provide training to the student and other team members. Rainforth and York-Barr define collaboration as "an interactive process in which persons with varied life perspectives and experiences join together in a spirit of willingness to share resources, responsibility, and regards in creating inclusive and effective educational programs and environments for students with unique learning needs."⁸²

Program Implementation

The occupational therapist provides services in collaboration with the student and his or her teachers, parents, employers, coworkers, and others as necessary to address the student's goals in the domestic, vocational, school, recreation, and community areas. Occupational therapy personnel (including the occupational therapist and the occupational therapy assistant) deliver transition services in the student's natural environments. Therefore, occupational therapy may provide intervention in the student's school, workplace, home, or any other relevant setting in the community. Collaborative problem solving with others involved in the student's environment is essential to help the student use alternative methods to complete the necessary activities.

For example, an occupational therapist may introduce and train the teacher in using assistive technology to help a student be able to access the computer at school to do written assignments. The occupational therapy practitioner may provide direct or consultative services to help minimize discrepancies in the student's abilities and the demands of any environment. Evaluating whether the student reaches his or her goals should be the outcome measure to evaluate the effectiveness of occupational therapy services.

Work Readiness Programs

Many times, people who have survived a major accident or illness cannot return to their prior employment and need to explore other options for employment. For example, Henry can no longer carry out the job demands of a roofer. Henry may really want to return to some type of meaningful work but needs guidance and direction to explore what his present abilities and work skills are so that he can set some realistic vocational goals.

A work readiness program is designed to help individuals who desire to work identify vocational options that match their interests, skills, and abilities. At Rancho Los Amigos National Rehabilitation Center in Downey, California, an occupational therapist developed and implemented an ongoing work readiness program as part of the Occupational Therapy Vocational Services. This is a 6-week program that meets three times a week for 2 hours. It consists primarily of group sessions with a few individual sessions. Topics addressed include the following: work habits, goals, interests, work skills, vocational exploration, job hunting strategies, and community resources. Instruction, group discussion, and hands-on exploration of work skills via standardized work samples and situational assessments are used to help people explore their readiness to work and discover their potential for pursuing training for a different occupation. Each person's program is individualized to address specific goals and interests. For example, Henry may be interested in working with a computer. He would be given the opportunity to do different work-related tasks using a computer so that he could see whether he has an aptitude for this type of work. If Henry was not familiar with the types of jobs that a person could do with a computer, he would learn how to do vocational research by using various reference books in the library or on the Internet.

A work readiness program can help people identify specific goals to pursue and develop a plan to help them work toward their goals. This program can help a person prepare for returning to work, but it does not provide a job for the participant. At the completion of the program, if a person demonstrates readiness to work, he or she can be referred to the State Department of Rehabilitation for assistance in job training and job placement. After completing a work readiness program, the occupational therapist can provide valuable information on a person's skills, aptitudes, and interests to assist the rehabilitation counselor in developing

a feasible plan for the worker. While Henry was attending the work readiness program, he identified the goal of becoming a computer support technician. Based on the vocational testing and research that he did during the program, this was determined to be a reasonable goal for him to pursue. He was referred to the State Department of Rehabilitation for job training and job placement in his new career.

Community-Based Services

Historically, work-related programs took place within medical model clinics, such as rehabilitation programs or settings designed for work intervention, as opposed to the site where the worker actually performed his or her role.⁹⁰ Today, work programs are increasingly being located in the community in which the participant resides or within the work setting itself.⁹⁰ This trend toward increased community practice is probably due to changes in the field of occupational therapy and external forces influencing the practice. Current thinking in occupational therapy recognizes that “occupational dysfunction is multidimensional, resulting from the interplay of biological, psychological, and ecological factors.”⁹⁰ Decreasing reimbursement in medical model settings has resulted in occupational therapists exploring other options for reimbursement in the community.

Funding for most community-based programs is derived from grants or contracts through local, state, or federal governments, as well as foundations. Grants are funds that are awarded for a specific purpose and a specific period, usually for research or a service project, “based on a submission of a creative original proposal.”⁹⁰ Contracts also provide funding for research or service projects; however, the funding agency defines the scope of the project and requests bids from competing organizations in the community. The majority of funding for community-based programs comes from foundations; “foundations are operated by philanthropic families, corporations, or community agencies that have reserved significant amounts of money for the purpose of supporting charitable organizations and programs to address specific community needs.”⁹⁰ Many associations and civic groups, such as the United Way, American Head Injury Foundation, Kiwanis Club, and others, provide funding for community projects related to specific areas of interest. It is important to note that community-based programs should develop a broad financial base with multiple funding sources for programs to “survive and thrive” in the long run.

Community Rehabilitation Programs

There are almost 600 community rehabilitation programs (CRPs) with federal contracts under the Javits-Wagner-O’Day (JWOD) program according to NISH, formerly the National Industries for the Severely Handicapped. These community-based nonprofit organizations train and employ

individuals with severe disabilities (primarily developmental disabilities and blindness) and provide quality goods and services to the federal government. The CRPs subcontract work from various industries to allow individuals with severe disabilities the opportunity to be productive, earn a competitive wage, and contribute to society. See the NISH Website (www.NISH.org) for more details. These programs receive most of their funding from regional centers or the Office of Vocational Rehabilitation. Although most of these programs are run by non-occupational therapy personnel, this is an area that some occupational therapists may want to explore for future involvement. There is a great need for these types of programs for individuals with other severe, chronic disabilities (such as brain and spinal cord injuries), but creative funding needs to be obtained to support them.

Homeless Shelter Programs

An emerging practice area for occupational therapists is working with persons who are homeless. Because of the increasing number of persons experiencing homelessness, Congress enacted the Stewart McKinney Homeless Assistance Act of 1987 (Public Law 100-77).³⁴ This act was designed to meet the needs of those who are homeless by providing funds for emergency shelters, food, health care, housing, education, job training, and other community services. The act funded a Department of Labor project to plan, implement, and evaluate the effectiveness of a comprehensive spectrum of employment, training, and other support services to help persons who are homeless to locate and sustain employment. Based on the Job Training for the Homeless Demonstration Program (JTHDP), which consisted of 63 organizations across the United States that provided comprehensive services for persons who were homeless from September 1988 to November 1995, the Department of Labor created a best practices guide.⁹⁰ Box 14-7 lists the findings of the JTHDP, which recommended that a sponsoring agency provide the core services or that the agency develop linkages with other local human service providers to assist persons who are homeless in obtaining and sustaining employment.

Occupational therapists have the skills to design and implement programs that incorporate the JTHDP recommendations for best practices. Client-centered job readiness and job-training programs can and have been developed for community service agencies to address the concerns of persons who are homeless. This population desires intervention services that are “sensitive, respectful, and responsive to their self-identified needs.”¹⁰

Occupational therapy practitioners work with those who are homeless, as well as with agencies providing services for people who are homeless, to build skills for accessing resources, solving problems by identifying strengths and assets, and learning to critically analyze situations for win-win situations for employers and the persons who are homeless.

Box 14-7

Core Services Necessary According to the Job Training for the Homeless Demonstration Program

Case management and counseling
 Evaluation and employability development planning
 Job training services (e.g., remedial education, basic skills training, literacy instruction, job search assistance, job counseling, vocational and occupational skills training, and on-the-job training)
 Job development and placement services
 Post-placement follow-up and support services (e.g., additional job placement services, training after placement, self-help support groups, mentoring)
 Housing services (e.g., emergency housing assistance, evaluation of housing needs, referrals to appropriate housing alternatives)
 Other support services (e.g., child care, transportation, chemical dependence evaluation, counseling, and referral to outpatient or inpatient treatment as appropriate)
 Mental health evaluation, counseling, and referral to treatment
 Other health care services
 Clothing
 Life skills training

Welfare-to-Work Programs

Congress passed the Personal Responsibility and Work Opportunity Reconciliation Act (Public Law 104-193) in 1996 to move people from welfare to work.¹⁰ It required welfare recipients to find work after receiving 2 years of public assistance. The Balanced Budget Act of 1997 (Public Law 105-33) provided funds for welfare-to-work grants. These grants are for training long-term recipients of welfare or public assistance to enter the job market in unsubsidized jobs. People who are most difficult to place because of multiple barriers to work, such as low academic skills, poor work history, or those who need substance abuse treatment, are the target of these grants. A substantial percentage of welfare recipients have learning problems, mental health and substance use disorders, and issues of domestic violence interfering with their sustained employability.⁹⁰

Welfare-to-work programs are another innovative practice area for occupational therapists. Therapists who are interested in entering this area of practice must find out which agencies within the local or state communities control the welfare-to-work funds. Occupational therapists can subcontract with these agencies and collaborate with them. This information can be accessed from the National Governors Association (NGA) Center for Best Practices welfare reform Website.⁶⁴ Private foundations that are involved in the welfare-to-work programs may also be a source of entry for occupational therapists.

There are many barriers that a person receiving welfare must face to enter into competitive employment. Lack of transportation, lack of childcare, problems with domestic violence, illiteracy, lack of housing, substance abuse, and medical needs can interfere with a welfare recipient's ability to obtain and retain a job.¹⁰ Successful welfare-to-work programs attempt to break these barriers down. For example, programs combine basic education and job development, provide refurbished cars for transportation to work, and provide one-on-one mentoring for improving self-sufficiency. Transitioning welfare recipients to the workplace presents a challenging practice area for occupational therapists to use their creativity to design and deliver effective services to help clients set goals, explore vocational options, and introduce them to different community resources to achieve successful and continued employment.⁴³

Ticket to Work

The Ticket to Work and Work Incentives Improvement Act was enacted in December 1999. This law created a voluntary program for recipients of Supplemental Security Income (SSI) and Social Security Disability Insurance (SSDI) to receive job-related support services and encourage beneficiaries to return to work and pursue their employment goals.⁹⁶ Those who have tickets can go to any Employment Network (EN), an organizational entity (state or local, public or private) that has contracted with the Social Security Administration (SSA) to coordinate and deliver employment services, vocational rehabilitation services, and/or other support services under the Ticket to Work Program. Interested individuals can contact MAXIMUS, a private company contracted by the SSA to oversee and process support to sustain ongoing Ticket to Work Program operations. They can be reached toll free at 1-866-968-7842 or contacted via the Website www.yourtickettowork.com or www.ssa.gov/work. The Ticket to Work Program creates opportunities for occupational therapists to serve on advisory panels, work as program managers, or provide employment support services.⁴⁵

Future Trends

The population of older workers is increasing, whereas the population of younger workers between 25 and 44 is decreasing.⁸⁸ According to the Bureau of Labor Statistics, between 1977 and 2007, *employment of workers 65 and older* increased 101% as compared with 59% for *total employment (16 and older)*.⁹ It is predicted that there will be a shortage of younger workers to replace the baby boomers when they retire, thereby creating a gap in the labor market. One proposal to fill this gap would be to employ more people with disabilities.⁸⁸ Occupational therapists can work with human resource managers to educate and provide resources for workplace accommodations. The Society for Human Resource Management has recently partnered with the

Threaded Case Study | Joe, Lorna, and Henry, Part 2

Reflecting back on the introductory case scenarios, the reader sees opportunities for the application of these comprehensive work-related occupational therapy interventions. For example, Joe's occupational therapist could conduct a job demands analysis of the laundry attendant position and a worksite evaluation at the hotel and spa where he worked before his spinal cord injury. Then the occupational therapist could determine whether Joe could successfully carry out the essential functions of that alternative job. The occupational therapist could recommend any modifications that needed to be done to make the work area wheelchair accessible. A functional capacity evaluation may be helpful to determine whether Joe could carry out any of the specific physical demands of the job on an occasional or frequent basis. Based on the results, the occupational therapist could then make recommendations to the physician and the employer for any reasonable accommodations that may be necessary for Joe to successfully return to work, as well as to inform them of any concerns regarding Joe's ability to safely meet the physical demands of the job.

After Lorna, the upholsterer with the repetitive stress hand injury, obtains a general occupational therapy evaluation and intervention for her acute injuries in the clinic, she could similarly benefit from an ergonomic assessment and

intervention at her workplace. The goal of an ergonomic assessment and intervention would be to eliminate the risk factors that contributed to her original injury and to avoid recurrence of future problems. The occupational therapist could communicate with Lorna's employer about developing an in-house ergonomic and injury prevention program at the company to reduce the number of work-related musculoskeletal disorders occurring at the workplace.

Finally, contemplate the third scenario, which involves Henry. Henry needs the assistance of an occupational therapy practitioner to help him discover what type of work that he would best be suited for while taking into consideration his present physical and cognitive abilities and limitations. He could also benefit from a comprehensive vocational evaluation to assess his cognitive and physical abilities, work habits, work skills, and work tolerances, as well as interests and attitudes, to determine whether he could return to any other type of work. Another alternative would be for Henry to participate in a work readiness program. The same areas assessed during a vocational evaluation would also be addressed in the work readiness program; however, Henry could also benefit from a discussion on work-related topics, as well as receive peer interaction and feedback on his work performance, work habits, and attitudes.

Office of Disability Employment Policy (ODEP).⁸⁸ This collaboration reveals that human resource professionals are seeking support and services for hiring and accommodating workers with disabilities.

Baby boomers represent one of the largest percentage of the working population.⁸⁸ As they age, employers may need to be sensitive to workers in whom multiple disabilities develop that have an impact on their job performance. Changes in the workplace offer new opportunities for occupational therapists to help aging workers stay employed with their functional limitations. As older workers retire, occupational therapists can help individuals plan for their retirement and explore ways to remain active in the community by participation in leisure pursuits or volunteer activities. Occupational therapists can help older individuals identify their strengths and abilities and provide community resources to allow meaningful participation in valued occupations.

Summary

This chapter provides an overview of the varying types of work programs in which occupational therapists are currently practicing, as well as identifies and discusses areas for further involvement. There are tremendous opportunities for occupational therapists and certified occupational therapy assistants to expand their role and involvement in

hospitals, schools, industrial settings, and the community in general in the area of work practice. Occupational therapy practitioners are challenged to take a proactive approach in advocating the need for and benefit of these types of work-related programs in all communities to help restore the worker role in many people's lives.

Review Questions

1. How has involvement of occupational therapy in work programs evolved over the years?
2. What is the role of occupational therapy in work programs?
3. Describe the difference between an FCE and a vocational evaluation.
4. What components are usually included in an FCE report?
5. Describe the difference between work hardening and work conditioning.
6. List the common applications of the results of a JDA.
7. What interventions are used to determine whether someone is capable of returning to a specific occupation after an injury?
8. Discuss the ergonomic design considerations for workstations, seating, visualizing job tasks, tools, and materials handling.

9. List and discuss the eight important elements of corporate injury prevention plans.
10. Why are occupational therapists good candidates for assisting companies in the development of injury management programs?
11. Name and describe some innovative types of work programs in which occupational therapists can be involved in the community.

Americans With Disabilities Act and Related Laws That Promote Participation in Work, Leisure, and Activities of Daily Living

15

BARBARA L. KORNBLAU

■ Chapter Outline

Americans with Disabilities Act

Title I: employment

Changes in the ADA
Individuals not covered by the ADA
Qualified individuals
Essential job functions
Reasonable accommodations
Discrimination under the ADA
Limiting, classifying, or segregating
Contractual relationships that discriminate
Using standards, criteria, and methods of administration that discriminate
Discrimination based on association with an individual with a disability
Failing to make a reasonable accommodation
Employment tests that screen out individuals with disabilities
Administering tests to measure physical attributes, not skills or aptitudes

Retaliating against individuals who file discrimination claims

Conducting pre-employment medical exams or inquiries
Preplacement screenings and functional capacity assessments

The role of the occupational therapist

Title II: state and local government services

Title III: public accommodations

The role of the occupational therapist

Air Carrier Access Act

Discrimination prohibited under the ACAA

Air carriers' obligations

Role of the occupational therapist

Fair Housing Act

Advocacy as intervention

Summary

■ Key Terms

Individual with a disability	Undue hardship
Major life activities	Discrimination
Qualified person with a disability	Direct threat
Essential job functions	Places of public accommodation
Reasonable accommodations	Auxiliary aids
	Accessibility audit

■ **Learning Objectives** *After studying this chapter, the student or practitioner will be able to do the following:*

1. Explain how the Americans With Disabilities Act (ADA) defines disability and how that definition may apply to clients seen by occupational therapists.
2. Compare and contrast definitions of discrimination and discuss how they may apply to clients served by occupational therapy.
3. Recognize and define specific terms used in the ADA, Fair Housing Act, and Air Carrier Access Act.
4. Discuss the roles that occupational therapy can play in advocating for clients under the ADA, Fair Housing Act, and Air Carrier Access Act.
5. Discuss the roles that occupational therapy can play in consulting with employers, places of public accommodation, airline carriers, and landlords.
6. Explain the process used to determine essential job function.
7. Analyze reasonable accommodations as an intervention strategy in occupational therapy and explain the decision-making process involved in making reasonable accommodations.
8. Outline the process for removing physical and other barriers to access to places of public accommodation and the steps necessary to perform an accessibility audit.
9. Prepare and train employers, coworkers, supervisors, airline employees, and those who work with the public to treat individuals with disabilities with dignity and respect.

Threaded Case Study | Carlotta

Carlotta is a 50-year-old woman with severe rheumatoid arthritis. Since her most recent exacerbation, she finds that she must use a wheelchair for mobility. She has always prided herself on her independence and does not want to rely on her children or husband for assistance. She loves going to the movies, shopping, and traveling. Carlotta works as a Spanish teacher at the local high school.

She comes to the occupational therapist (OT) concerned about several things. How will she be able to participate in her work and leisure occupations from her wheelchair when some places (and people) in the community, including her classroom, are not wheelchair friendly or accessible? How will she manage airplane travel from a wheelchair? How can she independently participate in activities of daily living from a wheelchair when her landlord of 12 years will not allow her to make the changes needed in her apartment?

This chapter addresses Carlotta's concerns by expanding the concept of occupational therapy interventions to include advocacy as a key concept of intervention. As we address the occupations significant to Carlotta, we look at three laws for guidance and support in promoting occupational performance. We also look to these laws to support our intervention plan. These laws include the Americans With Disabilities Act (ADA),⁷⁹ including the Americans With Disabilities Act Amendments (ADAA)⁸⁰ and the 2010 ADA Standards for Accessible Design, the Air Carrier Access Act,⁷⁷ and the Fair Housing Act.⁹² Each law provides an avenue for occupational therapy intervention that promotes the greater good for many individuals with disabilities. Each law also provides specific support for our efforts to promote our client's desire to increase and improve her participation at work, at home, and in the community.

Carlotta's evaluation shows that as a person with a chronic disability, she is a very sophisticated player. Over almost 25 years of living with arthritis, she has acquired many adaptive devices, such as reachers, jar openers, and bathtub benches, to make her life easier, facilitate independent participation,

and prevent further damage to the joints of her hands. She requires the assistance of others for some tasks.

Her occupational profile shows that her job as a Spanish teacher at a large private school where she has worked for 18 years is very important to her. She believes that she can do her job but will have some difficulty navigating the classroom from her wheelchair because of the presence of multiple levels. Her classroom is the former orchestra classroom. She also expresses concerns about continuing her weekly excursions to the movies. How can she navigate the old theater in town in which the old upstairs balcony was turned into a separate screen theater with a one-flight walk up? Before she began to use a wheelchair herself, she saw wheelchair users at the local shopping mall struggling to get in the door, and she believes that this will present a barrier to her shopping or, as she puts it, "retail therapy." How will she manage at the airport and aboard airplanes in her quest to find the perfect bed and breakfast (another hobby)? Finally, from her experience as an individual with a disability, she knows that she will need more adaptations in her bathroom to participate in activities of daily living. She is particularly concerned because her landlord has already told her that she cannot widen the bathroom door or install grab bars in the bathtub. She is interested in finding alternatives so that she can take care of herself and not have to move. She also expressed concern about her difficulty in carrying out a home aquatics program prescribed by her previous OT. She now requires assistance to get into the pool at her apartment complex, but the complex's rules do not allow guests on weekends.

Disability laws heavily influence the facilitation of participation in work, leisure, and the community. Ignoring disability laws can promote ineffective intervention plans. To move forward with an occupational therapy intervention plan, one must first understand the disability laws that affect the areas of concern to Carlotta and how these laws can provide a basis for intervention.

Americans With Disabilities Act

To understand the protection that the ADA affords Carlotta and the roles that the ADA provides for OTs and occupational therapy assistants (OTAs), one must first have a basic understanding of the ADA, its definitions, and how the courts have interpreted the law. Congress passed the ADA in 1990 in an effort to decrease discrimination against individuals with disabilities and promote their inclusion in the mainstream of society. The law's antidiscrimination provisions cover employment, certain state and local government services, public accommodations, communications, and public transportation. This chapter explores Title I (employment), Title II (state and local government services), and Title III (public accommodations) and how they affect occupational therapy practice.

Title I: Employment

Before the ADA became law, the Rehabilitation Act of 1973 prohibited discrimination against qualified individuals with disabilities in employment by three categories of employers: (1) the federal government, (2) employers who contract with the federal government to provide goods and service, and (3) employers who were recipients or beneficiaries of federal funding.¹⁰⁰

Congress extended that protection by expanding it to private employers who are not dependent on federal funding by passing the ADA in 1990. Because one of Carlotta's concerns is her work and whether she can continue to participate in her work from a wheelchair, knowledge of Title I of the ADA can provide a foundation for occupational therapy intervention.

Title I of the ADA prohibits discrimination against individuals with disabilities in employment with private, non-government employers who have 15 or more employees. In a nutshell, the prohibition against discrimination in Title I states:

No covered entity shall discriminate against a qualified individual on the basis of disability in regard to job application procedures, the hiring, advancement, or discharge of employees, employee compensation, job training, and other terms, conditions, and privileges of employment (42 U.S.C. 12112(a)).⁷⁴

To understand this statement, one must understand the terms used by answering the following questions:

- Who is considered “an individual with a disability” under the ADA?
- What is a “qualified individual with a disability” under the ADA?
- What is considered “discrimination” under the ADA?

The ADA refers to “individuals with disabilities” as opposed to “disabled individuals” to give voice to politically correct terminology that stresses the individual first, not the

disability. It defines the phrase “individual with a disability” broadly under three umbrella categories.

Changes in the ADA

When Congress passed the original ADA, it intended to create an inclusive society in which people with disabilities would work, engage in everyday community activities, and benefit from state and local benefits and services side by side and on the same basis as people without disabilities.⁷⁹ Looking back on the 20th anniversary of the ADA, individuals with disabilities have achieved success in access to participation in the community and government benefits and services.

Employment under Title I proved to be the biggest disappointment with the ADA. Greeted with great fanfare by the disability community, the courts took a civil rights bill intended to provide employment rights for people with disabilities and decimated its intent. Though originally given a broad mandate by Congress and intended to cover all who fit within the definition of “individual with a disability,” the Supreme Court and lower courts acting under its mandate chipped away at these protections and narrowed the definition of “individuals with a disability.”

Ruling on three cases in 1 day, the Supreme Court severely restricted protection for individuals with disabilities in the employment arena.⁷⁸ For example, the Supreme Court ruled that individuals were not considered persons with disabilities if they used ameliorative measures to decrease the impact of their disabling condition.⁹⁸ The lower courts interpreted this to mean that someone with diabetes who took insulin was not considered a person with a disability.⁹¹

In *McClure v. General Motors Corp.*, 75 Fed. Appx. 983 (5th Cir. 2003), the court held that Mr. McClure's fascioscapulothoracic muscular dystrophy, which prevented him from lifting his arms above his shoulders and required him to use an accommodation to perform his job as a mechanic, did not make him a person with a disability. The court stated, “But the evidence [of limitations from his fascioscapulo-humeral muscular dystrophy] does not show that these differences rise to the level of severe restrictions.” Like Carlotta, Mr. McClure had many adaptive devices that “ameliorated the effects” of his disability and its impact on everyday activities.⁹⁶

The lower courts interpreted the Supreme Court's restrictions to impose significant restrictions on individuals with intellectual disabilities as well. In *Littleton v. Wal-Mart*, No. 05-12770 (11th Cir. 2007), Mr. Littleton had an intellectual disability and, with the assistance of a job coach, went for an interview with Wal-Mart for a shopping cart attendant position. Although arrangements were made in advance for the job coach to attend the interview, when they arrived for the interview, Wal-Mart would not allow the job coach to attend the interview. Mr. Littleton did not get the job. The court acknowledged that Mr. Littleton had an intellectual disability, which it referred to as “mental

retardation.” In denying Mr. Littleton a trial and declaring that he was not an individual with a disability, the court said in its opinion, “he has pointed to no evidence which would create a genuine issue of material fact regarding whether he was substantially limited in the major life activity of learning because of his mental retardation [now referred to as intellectual disability].”⁹⁵

The court also said that episodic conditions, such as epilepsy, did not qualify as a disability. For example, in *Todd v. Academy Corp.*, 57 F. Supp 2d 448 (S.D. Tex. 1999), the court found that Mr. Todd was not an individual with a disability because the effects of his seizures were not substantial since they lasted “only” 10 to 15 seconds and did not occur frequently enough.¹⁰³ In *EEOC v. Sara Lee*, 237 F. 3d 349 (4th Cir. 2001), the court held that the employee was not entitled to a reasonable accommodation from the employer because the employee took medications for seizures and therefore was not a person with a disability.⁹⁰

The U.S. Supreme Court further limited the rights of people with disabilities when it reviewed what it means to be “substantially limited in a major life activity” in the case of *Williams v. Toyota Motor Mfg.*¹⁰⁹ Mrs. Williams had tendinitis and cumulative trauma syndrome. The court declared that people with disabilities had to have multiple limitations in their everyday activities to be considered a person with a disability; one limitation was not enough.¹⁰⁹

As a result of these decisions, the ADA faded into a hollow promise for people with disabilities in employment. Its definitions are meaningless. Its safeguards no longer provide protection for people with any disability. Veterans returning from the wars in Iraq and Afghanistan with limb loss feared that employers could discriminate against them and that the courts would not stand behind them because of the mitigating affect of their prostheses. Carlotta could have found herself without the ADA’s protection because her wheelchair and adaptive aids mitigated the impact of her arthritis.

The disability advocacy community lobbied Congress to change the law to restore Congress’ original intent to ensure that people with disabilities could work and not face unnecessary discrimination. These efforts led to the passage of the ADA Amendments Act (ADAAA), which specifically rejects the Supreme Court’s decisions and broadens the definitions portion of the ADA to return the law to its original intent: a broad scope of protection under the ADA.⁷⁴ It also extended all of its changes to the Rehabilitation Act of 1973.⁸⁰

The first definition states that with reference to individuals, disability means “(i) A physical or mental impairment that substantially limits one or more of the major life activities of such individual.”⁴¹ A physical or mental impairment includes “any physiological disorder or condition, cosmetic disfigurement or anatomical loss affecting one or more of the following body systems: neurological, musculoskeletal, special sense organs, respiratory (including speech organs),

cardiovascular, reproductive, digestive, genito-urinary, hemic and lymphatic, skin, and endocrine.”⁴⁴ Physical or mental impairment as defined includes most of the traditional medical diagnoses that OTs treat, including, for example, individuals with multiple sclerosis, spinal cord injury, cerebral vascular accident, and cerebral palsy, as well as Carlotta’s arthritis, which affects the musculoskeletal system. Mental or psychologic impairments include “any mental or psychological disorder, such as an intellectual disability [formerly termed ‘mental retardation’], organic brain syndrome, emotional or mental illness, and specific learning disabilities.”⁴⁵

The ADAAA broadened the meaning of the phrase “substantially limits” based on Congress’ finding that the former regulation that defined “substantially limited” to mean “significantly restricted” was inconsistent with congressional intent because the standard was too high.⁸¹ The ADAAA specified that the term “substantially limits” be interpreted consistently with the findings and purposes of the ADAAA enacted in 2008.⁸²

The implementing regulations incorporated the policies that Congress outlined in the ADAAA into a series of rules to help define “substantially limiting.” The closest one to an actual definition states:

An impairment is a disability within the meaning of this section if it substantially limits the ability of an individual to perform a major life activity as compared to most people in the general population. An impairment need not prevent, or significantly or severely restrict, the individual from performing a major life activity in order to be considered substantially limiting. Nonetheless, not every impairment will constitute a disability within the meaning of this section.⁴⁸

The remaining rules explain how to interpret this general rule. As Congress intended, the rule shall be interpreted “broadly in favor of expansive coverage” so that people like Carlotta are covered by the ADA.⁴⁸ Furthermore, lawsuits brought under the ADA should focus on whether employers “complied with their obligations and whether discrimination has occurred, not whether an individual’s impairment substantially limits a major life activity.” Accordingly, the threshold issue of whether an impairment “substantially limits” a major life activity should not demand extensive analysis.⁴⁸

At the same time, the regulations say that the “determination of whether an impairment substantially limits a major life activity requires an individualized assessment.”⁴⁷ This is an area where OTs can provide some consultation. If Carlotta needed to prove that she was an individual with a disability, the OT can help provide the individualized assessment of her disability and contribute the major life activities limited by Carlotta’s arthritis to the process. The regulations reiterate that the standard used for this assessment is lower than the previous “substantially limited” standard.⁴⁷

The regulations also say that the “comparison of an individual’s performance of a major life activity to the performance of the same major life activity by most people in the general population usually will not require scientific, medical, or statistical analysis.”⁴⁹ However, an individual with a disability, like Carlotta, could present “scientific, medical, or statistical evidence” to show the comparison, which could include evidence from an occupational therapy assessment.⁴⁹

The other rules governing “substantially limited” incorporated the specific concerns that Congress expressed in the law to address the problems created by the Supreme Court cases: mitigating measure, impairment that is episodic or in remission, and impairment in only one major life activity. The ameliorative effects of mitigating measures will no longer play a role in the determination of whether an impairment substantially limits a major life activity.⁵⁰ Congress specified examples of mitigating measures as follows:

1. “medication, medical supplies, equipment, or appliances, low-vision devices (which do not include ordinary eyeglasses or contact lenses), prosthetics including limbs and devices, hearing aids and cochlear implants or other implantable hearing devices, mobility devices, or oxygen therapy equipment and supplies”
2. “use of assistive technology”
3. “reasonable accommodations or auxiliary aids or services” or
4. “learned behavioral or adaptive neurological modifications.”⁸²

An episodic impairment or one that is in remission is considered “disability if it would substantially limit a major life activity when active.”⁵¹ An impairment need limit only one major life activity to be considered a substantially limiting impairment.⁵² For Carlotta, this means that none of the following circumstance—her use of assistive technology, a limitation only in walking, and remission of her arthritis—would prevent her from qualifying as substantially limited or a person with a disability.

Major life activities include many areas of occupation and related activities of daily living (ADLs) functions, including “but...not limited to, caring for oneself, performing manual tasks, seeing, hearing, eating, sleeping, walking, standing, sitting, reaching, lifting, bending, speaking, breathing, learning, reading, concentrating, thinking, communicating, interacting with others, and working.”⁴⁶ Another category of major life activities includes “operation of a major bodily function, including functions of the immune system, special sense organs and skin; normal cell growth; and digestive, genitourinary, bowel, bladder, neurological, brain, respiratory, circulatory, cardiovascular, endocrine, hemic, lymphatic, musculoskeletal, and reproductive functions. The operation of a major bodily function includes the operation of an individual organ within a body system.”⁴⁶

■ Box 15-1

Impairments and Substantially Limiting Major Life Activities

- Deafness substantially limits hearing.
- Blindness substantially limits seeing.
- An intellectual disability (formerly termed mental retardation) substantially limits brain function.
- Partially or completely missing limbs or mobility impairments requiring the use of a wheelchair substantially limit musculoskeletal function.
- Autism substantially limits brain function.
- Cancer substantially limits normal cell growth.
- Cerebral palsy substantially limits brain function.
- Diabetes substantially limits endocrine function.
- Epilepsy substantially limits neurologic function.
- Human immunodeficiency virus (HIV) infection substantially limits immune function.
- Multiple sclerosis substantially limits neurologic function.
- Muscular dystrophy substantially limits neurologic function.
- Major depressive disorder, bipolar disorder, post-traumatic stress disorder, obsessive compulsive disorder, and schizophrenia substantially limit brain function.

Adapted from 29 C.F.R. §1630.2 (j) (3) (i-iii).

Sometimes, when determining whether a person is limited in a major life activity, one may want to look at the condition under which individuals perform the activities, the manner in which they perform them, and/or how long it takes individuals to perform them.⁴⁸ However, the regulations give examples of certain disabilities that one could easily conclude will substantially limit at least the major life activity indicated in Box 15-1.

The occupational therapy evaluation provides the information that the court will want to use to make a determination whether an individual is substantially limited in major life activities. OTs may find themselves assisting employers, attorneys, and others by providing this information, if requested.

The occupational therapy evaluation of Carlotta shows that she has arthritis, which substantially limits the major life activity of walking. Carlotta’s arthritis also substantially limits her musculoskeletal function. She has difficulty participating in or is unable to participate in a variety of tasks related to everyday living. In light of these limitations, she probably falls under the first definition of disability.

The second definition of an individual with a disability under the ADA includes someone who has a record of having had such an impairment as described in the first definition.⁴² This category includes persons with a history of a disabling condition, such as an individual who had multiple sclerosis that is now in remission or someone cured of hepatitis C.

The third definition of an individual with a disability includes situations in which someone is regarded as having

a substantially limiting impairment that is a perception of a disability based on myths, misperceptions, fears, and stereotypes.⁴³ For example, suppose a morbidly obese individual, Sue, seeks a promotion to a position that requires frequent trips out of town. The person empowered to decide whether Sue gets that promotion assumes that Sue will have difficulty managing the traveling because of her size. The manager is concerned that Sue will struggle with walking through the airports, breathing, and other nonsedentary aspects of her job. Sue has had a perfect attendance record and has always received excellent performance appraisals. The manager bases his failure to hire Sue on his assumptions about her supposed difficulty walking, breathing, and completing nonsedentary tasks, and these assumptions are simply not true. The manager regards Sue as being an individual with a substantially limiting impairment.

Individuals Not Covered by the ADA

The ADA provides its protection against disability discrimination only for those who meet the criteria outlined earlier. This means that individuals with temporary impairments, such as a broken leg or after a knee replacement that is likely or expected to heal normally, will not find that the ADA protects them. Individuals who have impairments that are not substantially limiting, such as a visual limitation correctable with eyeglasses, will not find benefits under the ADA.

Furthermore, the ADA enumerates specific exclusions in its definition of disability. The ADA does not provide protection for individuals who fall into one of the following categories: transvestites, homosexuals, pedophiles, exhibitionists, voyeurs, gender disorders not caused by physical impairments, and other sexual behavior disorders.⁶³ The ADA further excludes from its protection illegal drug users, compulsive gamblers, kleptomaniacs, pyromaniacs, and alcoholics whose alcohol use prevents them from performing their jobs.⁶⁴ The ADA does provide protection against discrimination based on disability for recovering illegal drug users, as long as they participate in a rehabilitation program.

Qualified Individuals

Title I of the ADA does not protect all individuals with disabilities. It protects only those who are qualified individuals with a disability. The ADA specifies that “the term ‘qualified,’ with respect to an individual with a disability, means that the individual satisfies the requisite skill, experience, education and other job-related requirements of the employment position such individual holds or desires and, with or without reasonable accommodation, can perform the essential functions of such position.”⁵³ The first inquiry in deciding whether an individual with a disability meets the basic job requirements looks at individuals’ amount of experience, level of education, and skills necessary to perform the job. Carlotta meets these requirements since the school hired her as a qualified teacher more than 18 years ago, and thus she meets the basic education, skills, and

experience requirement. The next inquiry is whether the individual in question can perform the essential functions of the job.

Essential Job Functions

The ADA defines essential job functions as job duties fundamental to the position that the individual holds or desires to hold, as opposed to functions that are marginal functions.⁵⁴ Essential functions are those that the individual who holds the position must be able to perform with or without the assistance of a reasonable accommodation. One may consider a function essential because the position exists to perform the particular function. These essential functions are usually obvious. For example, a typist must type and a proofreader must proofread.

A function is essential because of the limited number of employees available who can share the particular function. For example, because there are only three Spanish teachers at Carlotta’s school, Carlotta must collaborate with the other two Spanish teachers to write and direct the annual Spanish language pageant. If the school employed 20 Spanish teachers, responsibilities may be divided so that Carlotta did not have to participate in the annual Spanish language pageant.

An essential function is also one in which the function is so specialized that the employer hires the person in the position for his or her particular expertise or ability to perform that function. For example, a brain surgeon is a highly specialized position, and the person in this position is hired to perform highly technical surgery.

Whether a function is an essential function is determined on a case-by-case basis. Specific evidence will support whether a particular function is essential. The Equal Employment Opportunity Commission (EEOC), the federal agency that provides enforcement of Title I’s provisions, and the courts will look at seven factors⁵⁵ as evidence of whether a function is essential (Box 15-2).

In some situations essential functions are obvious. For example, the essential functions of a receptionist’s position may include answering telephones, taking messages, and

■ Box 15-2

Seven Determining Factors of Essential Functions

- The employer’s judgment of which functions are essential
- Written job descriptions prepared before the hiring process begins
- The amount of time spent performing the job function
- The consequences of not requiring the performance of a particular function
- The terms of the collective bargaining agreement
- The work experience of previous employees who held the job
- The current work experience of incumbents in similar positions

greeting and announcing visitors. Typing may be a marginal function for a receptionist in a very busy office where the receptionist has not had to type anything at all over the last 6 months. One determines essential job functions on a case-by-case basis by looking at the facts of each situation. OTs can help determine essential job functions by looking at the job description, by conducting focus groups with employees, and by performing a job analysis as discussed in Chapter 14.

In determining essential job functions, the focus must be on the outcome or job tasks that employers expect employees to perform. The definition of essential job functions focuses on the concept of job duties or expected outcomes, not the physical demands required to perform a job duty. In other words, an essential function is a task that one must perform to perform the job, not a physical function. Essential functions are not bending, lifting, walking, climbing, or other physical demands. For example, a mail clerk for a large corporation includes delivering mail as one of his essential functions. The essential function is not walking and carrying the mail but rather the outcome of delivering the mail. If the mail clerk were not able to carry the mail, he could push the mail on a cart to accomplish the same result or outcome. Essential functions are what you do, not how you do it.

The job description, job analysis, and discussions with Carlotta about her job show that as a teacher, Carlotta must perform several essential functions, including grading papers and tests and recording their results, discussing student progress with parents, preparing lesson plans, motivating students, and maintaining order in the classroom. (Note that these essential functions are all specific job tasks and not physical functions such as “hand manipulation skills for writing” or “walking around the classroom.”) The occupational therapy evaluation shows that Carlotta is able to perform these functions for her position as a Spanish teacher. However, she may have difficulty maneuvering around the classroom to the desks of the individual students because of steps and multiple levels in the former band classroom in which she currently teaches Spanish. Carlotta will also have difficulty writing on the blackboard from a wheelchair. The key to facilitating Carlotta’s continued participation in the workplace lies in making reasonable accommodations.

Reasonable Accommodations

The ADA defines reasonable accommodations as any change in the work environment or in the way that work is customarily performed that enables an individual with a disability to enjoy equal employment opportunity.⁵⁶ Not all employees are entitled to reasonable accommodation. Employers need to make reasonable accommodations only for employees with disabilities who are qualified (Box 15-3).

Reasonable accommodations include three subcategories. First, reasonable accommodations include modifications or adjustments in the job application process that

Box 15-3

Reasonable Accommodations Decision Progression

Step 1: Is the Individual with a Disability Qualified (IWD)?

Does the individual meet one or more of the following criteria?

- A physical or mental impairment that substantially limits one or more major life activities
- A history of having had such an impairment
- Regarded as having such an impairment

If the worker is not an IWD, the employer does not have to accommodate.

Step 2: Is the Individual with a Disability Qualified?

Does the individual meet both of the following criteria?

- Individual satisfies the requisite skills, experience, education, and other job-related requirements of the job
- Individual can perform the essential functions of such position with or without reasonable accommodations

If the worker is not qualified, the employer does not have to accommodate.

Step 3: Is the Accommodation Reasonable?

- How much does the accommodation cost in relation to the size and budget of the business?
- Are there tax credits or deductions or outside funding sources to pay for the accommodation?
- Does the accommodation interfere with the operation of the business or the ability of other employees to perform their duties?

If it is not reasonable, the employer does not have to accommodate.

Courtesy Barbara L. Kornblau, ADA Consultants.

enable consideration of a qualified applicant with a disability for employment in a position that the person wants.⁵⁷ This would include reading a job application to an individual with dyslexia or modifying the way that a preplacement screening is performed to accommodate an individual with one hand. If Carlotta were to apply for another position, her potential employer would need to provide her with an accessible entrance to the human resources department so that she could obtain a job application.

The potential employer would also have to allow her to use a larger pen for filling out an application because she uses the larger pen to prevent joint changes in her hand. As an alternative, the potential employer can provide someone to assist her in filling out the application.

The modifications and adaptations that OTs most typically provide fall under the umbrella of the second category of reasonable accommodations. The second category includes modifications or adjustments to the work environment or to the manner or circumstances in which the position is customarily performed to enable an individual with

a disability who is qualified to perform the essential functions of that position.⁵⁸ OTs have traditionally been involved in this area by modifying job sites, including raising or lowering work heights, making a jig, or using a piece of equipment such as a cart to move objects rather than carrying them.

OT Practice Notes

OTs may assist human resources personnel in understanding how disabling conditions and the limitations in performance skills and client factors that accompany them can affect the hiring process. In addition, OTs can suggest appropriate reasonable accommodations available for the application and interview process that can prevent unintentional discrimination.

Carlotta's continued participation in her work environment will require reasonable accommodations in her intervention plan in the form of changes in the way that the work is performed. For example, Carlotta's employer could reasonably accommodate her by moving Carlotta to a different classroom—one that is all on one level and without steps or risers throughout the room to provide physical access to the students at their desks. Carlotta could also benefit from a laptop computer with a projector that has a liquid crystal display (LCD), which will eliminate the need for her to write on the board—an impossible task from a wheelchair level. (See [Chapter 14](#) for more detailed discussion of job modifications.)

OTs and OTAs working on the development of reasonable accommodations should note that employers must provide an effective reasonable accommodation, which means one that works, not the most expensive accommodation or the specific accommodation that the employee wants. Although the employee suggests the specific type of accommodation, ultimately, the employer gets to select the accommodation used. If a shoebox with some rubber bands wrapped around it works as well as the high-tech computerized gadget that the employee requests, the employer need only provide the shoebox.

The third category of reasonable accommodations includes modifications or adjustments that enable employees with a disability to enjoy equal benefits and privileges of employment as other similarly situated employees without disabilities enjoy.⁵⁹ For example, suppose the language department at Carlotta's school customarily holds an annual international fair for all of the students and their families at the school. The teachers compete by class for the best food, costumes, and projects. The teacher of the winning class wins prizes supplied by the Parent-Teacher Association (PTA). Under the ADA, the school would be required to hold the fair at an accessible location so that Carlotta could participate. This would also apply to the school's annual

holiday party and all other school functions for employees. OTs can improve awareness by employers, assist them in making reasonable accommodations, and help sensitize employers to the needs of individuals with disabilities in these situations.

According to the ADA, reasonable accommodations may include physical changes to make facilities accessible, in addition to other nonenvironmental changes. Depending on the individual circumstances, reasonable accommodations can include job restructuring, part-time or modified work schedules, reassignment to a vacant position, acquisition or modification of equipment or devices (such as Carlotta's laptop computer and LCD projector), appropriate adjustment or modification of examinations, training materials or policies, provision of qualified readers or interpreters, and other similar accommodations for individuals with disabilities.^{57,58}

For example, an individual who needs to begin kidney dialysis may find that leaving work early 3 days a week reasonably accommodates his needs. Allowing a cashier with fatigue from multiple sclerosis to sit instead of stand while working may reasonably accommodate her needs. Because of their knowledge of the limitations of impairments and how to adapt the work environment to the individual, OTs can suggest and/or design many of these accommodations while working together with the client. Carlotta has a good understanding of much of what she needs to reasonably accommodate her work needs, and her intervention plan should incorporate her insights and suggestions.

The most efficient way for employers to identify the reasonable accommodations that an individual employee may need is to initiate an informal, interactive process with the qualified individual with a disability in need of the accommodation.⁸⁴ Employers will find that individuals with a disability are often in the best position to determine which reasonable accommodations that they may need to enable job performance. OTs may participate in this effort when the parties need additional expertise to make these accommodations. The EEOC, the federal government agency charged with enforcing the ADA, recognizes the expertise of OTs in assisting to make reasonable accommodations.⁸⁸

The ADA provides an exception to the employer's requirement to provide reasonable accommodations for qualified individuals with disabilities. Employers need not provide reasonable accommodations when provision of the accommodation would cause an undue hardship to the employer. Undue hardship refers to any accommodation that would be unduly costly, extensive, substantial, or disruptive or that would fundamentally alter the nature or operation of the business.⁶⁰ For example, it would probably be an undue hardship for the school to fix Carlotta's classroom by ripping out the floor in the old band room to remove the risers and level the floor because it would eliminate the use of a very needed classroom for an extended period and might represent a significant expense. The

alternative, to swap classrooms with another teacher, would be more cost-effective and less disruptive.

Determination of whether an accommodation presents an undue hardship to the employer involves looking at whether the proposed action requires significant difficulty or expense when the following factors are considered⁶¹:

- Nature and cost of the accommodation needed in light of tax credits and deductions and/or outside funding
- Overall financial resources of the facility, the number of persons employed at the facility, and the effect on expenses and resources
- Overall financial resources, overall size of the business, and the number, type, and location of facilities
- Composition, structure, and functions of the workforce
- Impact of the accommodation on operation of the facility, including impact on the ability of other employees to perform their duties and impact on the facility's ability to conduct business

According to the Job Accommodations Network, a federally funded program that has provided technical assistance in making accommodations for more than 25 years, data show that more than 50% of all accommodations cost nothing. Furthermore, its statistics also show that employers experience financial gains from the decreased costs of training new employees, a decrease in insurance costs, and an increase in worker productivity.⁹³

Discrimination under the ADA

The ADA does not give one specific definition of discrimination. Instead, it specifies at least nine categories of activities considered discriminatory.

Limiting, Classifying, or Segregating

The first prohibited activity includes limiting, classifying, or segregating the employee because of his or her disability.⁶⁵ For example, if Carlotta's school were to require all employees who use wheelchairs for mobility to work in one wing of the first floor, it would be segregating the employees with disabilities. This section also forbids employers from asking any questions about an applicant's worker's compensation history during the interview or on the employment application since employers can use this information to limit or classify individuals because of their disability.

Poor disability etiquette can lead to limiting, classifying, and segregating individuals with disabilities in the workplace. The way that coworkers treat people with disabilities and the language that they use to refer to individual with disabilities can also make people feel bad or left out of the workplace culture. One method that employers may use to avoid limiting, classifying, or segregating employees because of their disabilities is to sensitize supervisors and other employees to working with individuals with disabilities. Nondisabled individuals who lack familiarity in socializing with individuals with disabilities may not know how to shake hands with a person who does not have a right

hand. They may shout at a person who is deaf instead of speaking clearly and facing the person with the hearing impairment.

OT Practice Notes

OTs can assist employers in providing sensitivity training experiences similar to those used in some occupational therapy program classrooms to develop an understanding of the disability experience. Giving coworkers time in a wheelchair or with a blindfold during planned activities can help them experience functional limitations, if only for a brief time, that may encourage the development of some sensitivity to how it feels to have limitations in performance and participation. Using lay language free of confusing jargon during this kind of training makes it easier to get the message across to coworkers unfamiliar with OT lingo.

OTs can work with supervisors and coworkers on basic disability etiquette tips such as using politically correct terminology in which, as mentioned earlier, the person comes before the disability. For example, using the phrase "a person who had a stroke" is better than calling someone a "stroke patient" or "stroke victim" because the word *victim* has negative connotations. Using the phrase "wheelchair user" is more appropriate than "wheelchair bound" because no one is physically bound to the wheelchair as a book is bound to its binding. [Box 15-4](#) gives more tips on disability etiquette. For tips on conducting the interview process, see [Box 15-5](#).

Contractual Relationships That Discriminate

The second prohibited activity includes participating in a contractual or other relationship that results in discrimination against qualified applicants or employees because of their disability.⁶⁶ This provision applies to collective bargaining agreements, contracts with employment agencies, and other contracts. For example, suppose Carlotta's employer contracted with an outside company to provide continuing education courses at her school. The continuing education company would have to comply with the ADA by offering reasonable accommodations when needed, such as allowing Carlotta to tape sessions or providing her with a note taker if she is unable to take notes during the classes. The OT could work with the continuing education provider to help develop other reasonable accommodations for Carlotta and other individuals with disabilities.

Using Standards, Criteria, and Methods of Administration That Discriminate

The third prohibited activity includes the use of standards, criteria, or methods of administration that are not job related and consistent with business necessity and have the effect of discrimination based on the disability.⁶⁷ For

Box 15-4

Disability Etiquette Do's and Don'ts

- Do try to treat an individual with disabilities as you would treat any other person.
- Don't raise your voice at someone because he or she is in a wheelchair or has a visual or hearing impairment.
- Do address the person, not the wheelchair, interpreter, or guide.
- Don't trap yourself into thinking, "If I were disabled, how would I feel?"
- Do refer to an individual with a disability as "an individual with a disability."
- Don't refer to an individual with a disability as "the quadriplegic" or "Mary is a diabetic or epileptic."
- Do cleanse your vocabulary of offensive, outdated terms such as wheelchair bound or stroke "victim" or as "afflicted with..." or "suffering from..."
- Don't refer to able-bodied persons as "normal."
- Do avoid generalizations such as "People with epilepsy are unpredictable" or "People with learning disabilities are not very intelligent."
- Don't apologize for comments such as "Let's take a walk" to an individual in a wheelchair or "Do you see my point?" to a person with a visual impairment.
- Do avoid statements such as "I admire your courage" or "You've done so much for a person in a wheelchair."
- Don't use outdated terminology such as "handicapped," "crippled," "retarded," "lame," "the disabled," or "the handicapped."
- Do provide assistance only in the manner requested.
- Don't take hold of an individual's wheelchair or push his or her wheelchair unless asked to do so.
- Do put yourself on the same level as the individual in a wheelchair as soon as possible by sitting down during the conversation or interview.
- Don't turn away when conversing with an individual with a hearing impairment.
- Do speak directly to the person, not the interpreter.
- Don't complete the sentences of an individual with communication impairments.
- Do rid your thinking of stereotypes about disabilities.
- Don't perpetuate another person's insensitivity to an individual with a disability.

Courtesy Barbara L. Kornblau, ADA Consultants.

example, an employer could not require that Carlotta possess a driver's license for promotion to Chair of the Spanish Department if driving is not an essential function of the position.

Employers may use a direct threat standard to exclude from employment individuals whose disabilities pose a direct threat to the health and safety of themselves or others in the workplace.⁶² However, the direct threat must pose a significant risk for substantial harm to the health or safety of the individual or others that employers or others cannot eliminate or reduce to less than a significant risk by

Box 15-5

Interview Do's and Don'ts

- Don't make notes about an individual's physical or mental condition.
- Do discuss reasonable accommodations when possible. The interviewee is an expert on accommodating his or her disability.
- Don't rely on body language as a measure during the interview process. Lack of eye contact or a mild grip handshake may be caused by an applicant's disability, not his or her lack of confidence.
- Do remember that individuals with disabilities may make poor interviewees if judged against many "traditional" interviewing standards.
- Don't try to put yourself in the applicant's place and ask yourself, "Could I do this job if I were disabled?"
- Do offer an applicant a job based on his or her abilities—not disabilities.
- Don't job stereotype.
- Do remember that communications skills are often an inaccurate measure of the intelligence, ability, or confidence of an individual with a speech or hearing problem.
- Don't patronize the applicant with a disability with your own body language.

Courtesy Barbara L. Kornblau, ADA Consultants.

reasonable accommodation. Employers must consider the duration of the risk, the nature and severity of the potential harm, the likelihood that the potential harm will occur, and the imminence of the potential harm.⁶²

For example, suppose Carlotta wanted to swap classrooms with a teacher whose classroom is on the second floor of the school, which has three stories and an elevator. The headmaster could not refuse to allow Carlotta to use this second-floor classroom because he fears that Carlotta, as a wheelchair user, would pose a direct threat in the event of a fire. The chance of a fire occurring is small; therefore, little likelihood exists that any harm will occur. Moreover, the school could develop an emergency plan in advance that would further lower the risk.

Employers must base the determination that an individual poses a direct threat on an individualized assessment of the person's present ability to safely perform the essential functions of the job. Employers must base the assessment on a reasonable medical judgment that relies on the most current medical knowledge and/or on the best available objective evidence.⁶²

The regulations suggest that employers seek opinions from professionals who have expertise in the disability involved or direct knowledge of the individual with the disability. The EEOC recognizes that documentation of direct threat can come from OTs "who have expertise in the disability involved and/or direct knowledge of the individual with a disability."⁸⁸ Often, a reasonable accommodation

can reduce the risk. For example, a teenager with epilepsy has a seizure every time that the buzzer goes off on the french fryer while working at the local fast-food restaurant. The OT suggests that the employer could reasonably accommodate him by changing the buzzer to a bell.

Discrimination Based on Association with an Individual with a Disability

The fourth prohibited activity includes excluding or otherwise denying equal job or benefits to a qualified individual because of a disability identified in an individual with whom the qualified individual is known to have a family, business, social, or other relationship or association.⁶⁸ For example, an employer could not refuse to hire Carlotta's husband because Carlotta has arthritis and is in a wheelchair and the employer is worried that Carlotta's husband may have excessive absences because of Carlotta's condition. In fact, this principle prohibits the employer from asking any questions that may reveal information about his wife's disability.

Failing to Make a Reasonable Accommodation

The fifth prohibited activity includes failing to make a reasonable accommodation after a request for a particular accommodation for a known disability of a qualified individual or denying someone employment to avoid providing a reasonable accommodation, unless the employer can show that the accommodation would impose undue hardship on operation of the business.⁶⁹ As discussed previously, the OT can play a major role in assisting employers to determine reasonable accommodations. As mentioned earlier, Carlotta's intervention plan includes her need for the following reasonable accommodations: a laptop computer with an LCD projector and a one-level classroom. Carlotta must request the specific accommodations that she wants. As part of the intervention plan, the OT may prepare a report as documentation to the school explaining Carlotta's need for the particular accommodations for submission with Carlotta's accommodation request. The OT may meet with the school to help staff members understand the needed accommodations. Should Carlotta's school fail to make the reasonable accommodations that she requests, it would violate this provision of the ADA.

The employer must know that a prospective or actual employee is an individual with a disability before its obligation to make accommodations arises. Courts have found that an employer cannot discriminate based on disability if it does not know about the disability (*Morisky v. Broward County*).⁹⁷ Vague statements about one's limitations or past are not sufficient to put the employer on notice of a disability.⁹⁷ Disabilities such as multiple sclerosis, arthritis, learning disabilities, and mental health disorders may not be as obvious to an employer as seeing someone in a wheelchair. For employees to obtain reasonable accommodations for these hidden disabilities, employees or potential employees must disclose their disability to the employer. OTs can

work with clients as employees or potential employees in determining whether to disclose the disability, when to disclose it, and how to disclose it.

Employment Tests That Screen Out Individuals with Disabilities

The sixth prohibited activity involves using employment tests that tend to screen out individuals with disabilities on the basis of their disability, unless the test is shown to be job related for the position in question and is consistent with business necessity.⁷⁰ The EEOC considers a test job related if it measures a legitimate qualification for the specific job in question.⁸⁸ A test is not consistent with business necessity if it excludes an individual with a disability because of the disability and is not related to the essential functions of the job.⁸⁸ For example, under this section of Title I, the private school where Carlotta works could not give a written, twelfth grade-level reading test to an individual with a known learning disability who applies for a janitorial position. The janitorial position requires reading labels, which are on a fourth grade reading level. That test would screen out the applicant based on her disability and is neither job related nor consistent with business necessity.

Administering Tests to Measure Physical Attributes, Not Skills or Aptitudes

The seventh prohibited activity involves failing to administer tests in a manner to ensure that when administered to a job applicant or employee with a disability that impairs sensory, manual, or speaking skills, the test results accurately reflect the skill, aptitude, or whatever other factor of the applicant or employee that the test purports to measure rather than the sensory, manual, or speaking skills, except when such skills are the factors that the test purports to measure.⁷¹ For example, in *Stutts v. Freeman*,¹⁰² an individual with dyslexia was denied a heavy equipment job because he could not pass the written test required to enter a training program. The standard that he pass a written test had the effect of discriminating against the plaintiff as a result of his disability because the test was not meant to test the applicant's ability to read and write but rather his knowledge of heavy equipment operation. Had the employer administered the test orally, the potential employer would have focused on evaluation of the applicant's qualifications for the job, not his ability to read the material.

Retaliating against Individuals Who File Discrimination Claims

The eighth prohibited activity prevents employers from retaliating against individuals who file claims for discrimination under Title I.⁷² Before an applicant can file a lawsuit in court under Title I, he or she must file a complaint with the EEOC. This section prohibits an employer from firing, demoting, or otherwise retaliating against an employee who files a charge of discrimination with the EEOC or otherwise pursues his or her rights under this law.

Conducting Pre-employment Medical Exams or Inquiries

The final prohibited activity keeps employers from conducting pre-employment medical examinations of an applicant or employee or inquiring into whether the applicant is an individual with a disability or the nature and extent of the person's disability before the employer extends an offer of employment to the applicant.⁷³ Under the ADA, a medical examination means a "procedure or test that seeks information about an individual's physical or mental impairments or health."⁸⁹ The EEOC considers a variety of factors in deciding whether a test is a medical exam. These factors include, among others, whether the test is administered or the results interpreted by a health care professional or someone trained by a health professional, whether the test is designed to reveal an impairment, and whether the test measures the applicant's performance of a task or his or her physiologic responses to performing the task.⁸⁹

Preplacement Screenings and Functional Capacity Assessments

This provision of Title I affects the way that OTs do business. OTs are often involved in preplacement screenings and functional capacity evaluations, which are sometimes considered under the category of fitness-for-duty exams. Employers often hire OTs to perform these tests, which are described more fully in [Chapter 14](#). The ADA regulations outline the types of testing that employers (or those acting on their behalf) may perform and the stages at which they may perform them.

The hiring process includes two relevant stages. The first stage, the pre-offer, occurs during the interview process, before an employer extends an offer of employment to an applicant or candidate. The second stage, the post-offer, occurs after the employer has made a hiring decision and extends an offer of employment to the applicant or candidate. We often speak of this offer of employment as a conditional offer of employment because it is subject to withdrawal under certain circumstances, which this chapter addresses later.

During the pre-offer stage, an employer may conduct only a simple agility test. Employers and OTs acting on their behalf may not conduct medical examinations or inquiries, pre-employment physical examinations, preplacement screening, or functional capacity assessments during the pre-offer stage. An agility test is a simple test that looks at one's physical agility. It is not a medical test. Agility tests do not involve medical examinations, physicians, or medical diagnoses. Employers may request clearance from the applicant's physician before administering an agility test.⁸⁸ The classic agility test for police recruits shows them running through tires, scaling a wall, and climbing ropes. Another example of a permissible agility test would include an employer asking an applicant to carry a piece of wall-board from one end of the construction site to the other.

Although employers may conduct these agility tests, ADA rules govern their use. If an employer chooses to use

an agility test, it must give the test to all similarly situated applicants or employees. If the agility test screens out individuals with disabilities, the employer must show that the test is job related, consistent with business necessity, and that the applicant could not perform the job with a reasonable accommodation.

During the post-offer stage, employers or those acting on their behalf may conduct agility tests, medical exams and inquiries, pre-employment physicals, preplacement screenings, and functional capacity assessments. If the employer chooses to give medical exams once it makes a conditional offer of employment, it must give the exam to all employees entering the same job category. The ADA does not require that a medical exam satisfy the job-related and consistent-with-business-necessity standards. However, if the employer withdraws a conditional offer of employment because of the results of the medical exam, the employer must be able to show the following: (1) the reasons for the exclusion are job related and consistent with necessity or the person is being excluded to avoid a direct threat to health or safety and (2) no reasonable accommodation was available that would enable this person to perform the essential functions without a significant risk to health or safety or the accommodation would cause an undue hardship.

As mentioned earlier, during the post-offer stage, employers and OTs acting on their behalf may perform preplacement screenings and functional capacity assessments. Both are subject to the same requirements as medical exams. In other words, although the tests need not comply with the job-related and business-necessity requirements, should the tests screen out individuals with disabilities, job related and business necessity become the required standard to meet. Reality dictates then that to comply with the ADA, the preplacement screening must be job related and test only the essential functions of the job. For example, assessing Carlotta's hand strength as a part of the interview process for hiring her as a Spanish teacher would violate this provision of the ADA because hand strength is not job related and not related to an essential job function.

Employers and those acting on their behalf must keep the results of all medical exams and inquiries confidential with some limited exceptions. These exceptions include work restrictions information, insurance purposes, government investigations of ADA complaints, and state worker's compensation and second injury funds, which are funds set up by some states to encourage employers to hire individuals with previous workers' compensation-related or other injuries.

This prohibition against inquiries into medical and disability-related information also extends to job applications and interviews. Employers cannot ask questions about someone's disability or questions that will lead to information about someone's disability during the job interview process. [Box 15-6](#) shows examples of questions that employers cannot ask during the interview process.

■ Box 15-6

Questions Not Permitted under the ADA

- How did you become disabled?
- Are you in good health?
- Have you recovered from your prior disability?
- How much can you lift?
- How far can you walk?
- Have you been in a wheelchair your whole life?
- Do you have a driver's license? (if the job does not require driving or if a reasonable accommodation cannot eliminate the driving)
- Does your wife, husband, child, or roommate have a disability?
- Who takes care of your disabled husband (or wife or child)?
- Have you ever been injured in an accident?
- Have you ever filed a claim for workers' compensation?
- How were you burned?
- Do you have any physical conditions that would prevent you from doing your job?
- Do you have a good back?
- Have you ever been hospitalized?

OTs can assist human resources professionals in the proper way to inquire into an individual's ability to perform the essential functions of a position without asking prohibited questions. Employers must base their interview questions on specific job functions, information that OTs gather from the job analysis described in more detail in Chapter 14. Ideally, the interviewer should have a job description prepared from the OT's job analysis and ask interviewees questions about the match between their skills and abilities and the job's essential functions.

The Role of the Occupational Therapist

OTs can work together with individuals with disabilities as part of their intervention plans to identify needed accommodations that will enable participation in the workplace and plan a strategy to obtain those accommodations from the employer. OTs can help their clients understand their right to reasonable accommodations under Title I of the ADA. This includes the need to request the specific accommodations needed and to furnish documentation of the need, which the OT can prepare for the client's submission to the employer. OTs may find themselves advocating for the accommodations to their clients' employer.

For example, as described earlier, Carlotta's OT can play a major role in her employer's provision of the accommodations that she needs. Carlotta and her OT identified the accommodations that she needs as part of her occupational profile and intervention plan. If the employer refuses to provide the accommodations after Carlotta provides the OT's documentation and if Carlotta eventually files a lawsuit, the OT may find himself or herself testifying in court about Carlotta's need for the accommodations.

OTs can also provide consultation services for employers who want to avoid litigation and seek advice on making reasonable accommodations for its employees with disabilities. If Carlotta's employer were proactive, he may have contacted an OT for advice on how to accommodate Carlotta.

This kind of consultation, in which the client is the employer, not the individual with a disability, usually begins with a job analysis (described in detail in Chapter 14) to see what the job requires. The therapist takes this information, compares it with the individual's limitations, and tries to develop accommodations to enable performance. This accommodation development stage cannot proceed without input from the person with the disability.

For example, the author was hired by a hospital to look at whether a nurse affected by some post-polio weakness and arthritis could use a scooter (wheelchair substitute-type scooter) as her requested accommodation to cut down on the number of steps that she took during the day. The nurse had filed a charge of discrimination with the EEOC, and the hospital's attorney suggested hiring an OT to see whether the requested accommodations were reasonable so that it could avoid a full-blown lawsuit. The head nurse could not imagine a nurse using a scooter. The author performed a job analysis and determined that the scooter was a reasonable accommodation. Convincing the head nurse that the scooter was reasonable took more work in the form of sensitivity training, to which the OT also contributes.

Title II: State and Local Government Services

Title II of the ADA prohibits state and local government entities and those with whom they contract from denying a qualified individual with a disability participation in or the benefits of services, programs, or activities that it provides to individuals without disabilities.²³ Title II's antidiscrimination protection in the employment of individuals with disabilities by state governments has been limited by cases decided by the U.S. Supreme Court. Individual state employees can no longer bring lawsuits for monetary damage in federal court when a state discriminates in its employment practices based on the disability.⁸⁶

Title II's other requirements look similar to those of Title III, described in detail later for nongovernment entities. However, Title II goes further in its requirement for state and local government services than for privately owned entities in one particular concept.

Title II requires that government agencies give qualified individuals with disabilities equal opportunity to participate in or benefit from the state or local government aid, benefits, or services.²⁴ This requires providing more access than in Title III's requirements to provide what is readily achievable, as described later in this chapter. Providing equal opportunity to state and local government services requires taking measures such as making facilities physically accessible, making policy changes, providing reasonable accommodations in the form of auxiliary aids and services,

providing accessibility in public transportation, and supplying communication aids such as 911 services for the hearing impaired, as well as other accommodations described more fully under Title III later. OTs can help state and local governments make some of the needed changes, as will be discussed further in this chapter.

Title II and Title III were amended through the rule-making process, and new regulations took effect March 15, 2011.¹⁰⁵⁻¹⁰⁷ Most of the changes apply to both Title II and Title III. Several are specific to Title II. In particular, residential housing programs and detention and correctional facilities run by state and local governments must now comply with the applicable design requirements listed in the new 2010 Standards for Accessible Design, called “the 2010 Standards.”^{106,108}

Title III: Public Accommodations

Title III of the ADA prohibits discrimination against individuals with disabilities in places of public accommodation (PPAs). One may find this description slightly misleading because despite its name, this section of the ADA covers privately owned entities that own or lease to others, places that affect commerce. In other words, PPAs are privately owned entities where business of some kind is transacted or affected. The term PPA covers 12 broad categories enumerated in the ADA (Table 15-1).²⁵ The U.S. Department of Justice, the federal government agency charged with overseeing and enforcing Title III, reports that more than 5 million PPAs exist in the United States.¹⁰⁴

The super rule, which forms the basis for Title III, prohibits discrimination as follows:

No individual shall be discriminated against on the basis of disability in the full and equal enjoyment of the goods, services, facilities, privileges, advantages, or accommodations of any place of public accommodation by any private entity who owns, leases (or leases to), or operates a place of public accommodation.²⁶

Under Title III, PPAs must remove barriers to access, and if it cannot remove the barriers, the PPA must provide an alternative or reasonable accommodation to provide access to the goods and services that it provides. Many think of the barriers that Title III addresses as architectural barriers or barriers in the physical environment, such as steps and curbs, that limit physical access to a place that one desires to go.

Although many view the requirements of Title III as a quasi-building code, removing barriers to access as described in the ADA refers to more than mere access through removal of physical barriers. It also refers to access caused by attitudinal barriers and rules and to policies based on myths, misperceptions, and fears about individuals with disabilities that act as barriers to their access to PPAs.

For example, before the ADA became law, some banks refused to allow individuals who are blind to have safe deposit boxes. The rationale behind this policy asserts that

■ **TABLE 15-1** | Places of Public Accommodation under Title III

Category of Public Accommodation	Examples
Places of lodging	Hotels, motels
Establishments serving food or drink	Restaurants, bars
Places of exhibition or entertainment	Movie theaters, stadiums
Places of public gathering	Convention centers
Sales or rental establishments	Bakeries, shopping malls
Service establishments	Laundromats, funeral homes, doctors' offices
Public transportation terminals	Train stations
Places of public display or collection	Museums, libraries
Places of recreation	Parks, zoos, amusement parks
Places of education	Preschools, private schools, colleges
Social service establishments	Daycare centers, senior centers
Places of exercise or recreation	Health clubs, bowling alleys, golf courses

because individuals who are blind cannot see what is in their safe deposit boxes, how can they remove things that they need from the box? Only the safe deposit box holder can go into the viewing booth. Based on misperceptions, banks believed themselves at risk for accusations of theft from the boxes and, as a result, disallowed individuals who were blind from benefiting from the services that they provided to individuals who were not blind. This practice discriminated against individuals with visual impairments. The ADA prohibits these practices and seeks to break down these kinds of barriers.

To further its mission of breaking down physical and attitudinal barriers, Title III specifies three broad principles that provide the foundation for its philosophy of inclusion of individuals with disabilities in society. First, PPAs must provide individuals with disabilities an equal opportunity to participate in or benefit from the goods and services offered.²⁷ Furthermore, PPAs must give individuals with disabilities an equal opportunity to benefit from the goods and services that they offers.²⁷ Finally, PPAs must provide the benefits in the most integrated setting possible.^{27,28}

PPAs can violate Title III's mandates against discrimination by doing the following, among other things.

- Refusing to admit an individual with a disability merely because he or she has a disability.²⁷ For example, a restaurant cannot refuse to admit and/or serve an individual with cerebral palsy because he or she drools.
- Failing to provide goods and services to individuals with disabilities in the most integrated setting appropriate to the individual's needs.²⁸ For example, a professional or college football team cannot segregate all wheelchair users in a "handicapped" section in the end zone. It must allow wheelchair users to sit with family members and disperse wheelchair seating throughout the stadium.
- Using eligibility criteria that screen out or tend to screen out individuals with disabilities from full and equal enjoyment of goods and services.³⁰ For example, retail stores located in a busy tourist area require that individuals using credit cards show a driver's license as proof of identification as a way of cutting down on the use of stolen credit cards. However, this practice screens out individuals with visual impairments or other disabilities who do not qualify for driver's licenses. The retail stores would have to accept state identification cards in place of a driver's license from individuals with disabilities who do not qualify for driver's licenses.
- Failing to make reasonable modifications in policies, practices, or procedures when the modifications are necessary to offer goods, services, or facilities to individuals with disabilities.³¹ The example given earlier regarding bank policies for safe deposit boxes and individuals who are blind is a good illustration of a policy that discriminates on the basis of disability. As another example, Great Grocery Store has a policy whereby cashiers must place all checks in a specific column in the cash drawer. Carlotta's OT recommended that she use large-print checks because she can write more legibly with larger print. She attempts to give the cashier a large-print check. The cashier refuses to take the check because it does not fit in the cash drawer column for checks. She also tells Carlotta that their policy is to accept large-print checks only from blind people. Great Grocery Store must modify its policies and accept Carlotta's check.
- Failing to take steps to ensure that individuals with disabilities are not excluded or denied services, segregated, or otherwise treated differently from individuals without disabilities because of the absence of auxiliary aids and services.³³ Auxiliary aids as used in the ADA include devices that OTs usually refer to as adaptive equipment or assistive technology. According to the regulations, auxiliary aids and services include, among other things, qualified interpreters on site or through video remote interpreting (VRI) real-time computer-aided transcription services, assistive listening devices, closed-captioned decoders on televisions, Braille materials, taped texts, and "acquisition or modification of equipment or devices."³³

For example, suppose Carlotta stays at a restored historic hotel in her quest for the perfect bed and breakfast. She finds that she can use the bathing facilities in her room only if she has a tub bench. The hotel would have to provide her with a bathtub bench as an auxiliary aid so that it will not exclude or deny her bathing services.

Two exceptions exist to the auxiliary aid provision requirement. The PPA need not provide an auxiliary aid that fundamentally alters the nature of the goods and services offered or causes an undue burden.³³ An undue burden means that provision of the auxiliary aid would cause significant difficulty or expense. The impact on the PPA varies, depending on such elements as the size of the business and its budget. A major corporation should expect to spend more money on auxiliary aids and services than a neighborhood "mom and pop" operation. A fundamental alteration in the nature of the goods and services offered would occur, for example, if an individual with a visual impairment requested management to raise the lights in a bar in which the lights are customarily turned down low to create a particular ambiance or atmosphere.

The PPA need not provide personal devices and services such as individually prescribed devices (e.g., eyeglasses) or services of a personal nature (e.g., eating, toileting, or dressing).³⁷ However, it would probably be a reasonable auxiliary service should Carlotta request that the restaurant cut her meat in the kitchen before serving her steak if weakness in her hands prevents her from performing this task.

- Failing to furnish auxiliary aids and services when necessary to ensure effective communication, unless an undue burden or fundamental alteration would result.³³ For example, Bob is deaf and needs a sign language interpreter to converse with others. When seeking counseling services at a private mental health clinic. He requests a sign language interpreter to enable him to communicate with the mental health therapist. The mental health clinic must provide the sign language interpreter unless it is an undue burden.
 - Refusing to remove architectural and structural communication barriers in existing facilities when readily achievable.³⁴ Readily achievable means removal of barriers that can easily be accomplished and carried out without much difficulty or expense.³⁴ The ADA regulations provide 21 examples of steps that PPAs can take to remove barriers (Box 15-7).
- The ADA regulations recognize that not all changes are immediately readily achievable. In concert with input from members of the disability community, the Justice Department set forth four priorities in the ADA regulations that PPAs should take to comply with the barrier removal requirements (Box 15-8).³³
- Refusing to provide access to goods and services through alternative, readily achievable measures when

Box 15-7

Examples of Steps to Remove Barriers

Installing ramps
 Making curb cuts in sidewalks and entrances
 Repositioning shelves
 Rearranging tables, chairs, vending machines, display racks, and other furniture
 Repositioning telephones
 Adding raised markings on elevator control buttons
 Installing flashing alarm lights
 Widening doors
 Installing offset hinges to widen doorways
 Eliminating a turnstile or providing an alternative accessible path
 Installing accessible door hardware
 Installing grab bars in toilet stalls
 Rearranging toilet partitions to increase maneuvering space
 Insulating lavatory pipes under sinks to prevent burns
 Installing a raised toilet seat
 Installing a full-length bathroom mirror
 Repositioning the paper towel dispenser in a bathroom
 Creating designated accessible parking spaces
 Installing an accessible paper cup dispenser at an existing inaccessible water fountain
 Removing high-pile, low-density carpeting
 Installing vehicle hand controls

removal of barriers is not readily achievable.³⁶ The ADA regulations give three examples of alternatives to removal of barriers, including, for instance, providing curb service or home delivery for an inaccessible restaurant, retrieving merchandise from inaccessible shelves or racks in the grocery store, and relocating activities to accessible locations.³⁶ For example, in pursuit of her movie hobby, Carlotta wishes to see the latest popular art film. A multiscreen cinema is showing the film, but the particular theater requires climbing a flight of steps. The theater must rotate the films to provide Carlotta access to the film that she wishes to see.³⁶

- Failing to provide equivalent transportation services and purchase accessible vehicles in certain circumstances.³⁸ For example, Robby Rat's Fantasy Garden, a large amusement park, provides trams to take people to their cars in its enormous parking lots. On one of her trips Carlotta takes her grandchildren to the Fantasy Garden. The Fantasy Garden must provide accessible transportation from the parking lot to the entry gates for Carlotta.
- Failing to maintain the accessible features of facilities and equipment.²⁹ For example, Streams Department Store must maintain its accessible ramped entrance into the store. This means shoveling snow in the winter and raking leaves in the fall so that Carlotta has access into the store on her trips to this city.

Box 15-8

Four Priorities to Comply with Barrier Removal Requirements

Priority One: Access into the PPA (Place of Public Accommodation)

First, the PPA should try to provide access to and into the PPA from public sidewalks, parking, or public transportation. In other words, provide a way for individuals with disabilities to get into the building. For example, this includes, among other things as may prove necessary in individual circumstances, installing a ramp to the entrance, widening entrances, and providing accessible parking spaces.³⁴ Under this provision, the PPA would be responsible for making sure that Carlotta can get from her parking space into the lobby of the movie theater.

Priority Two: Access to Areas Where Goods and Services Are Available

The second priority that the PPA should focus on is providing access to areas of public accommodation where it makes goods and services available to the public. This step answers the following question: Now that individuals with disabilities can enter through our door, how do we get them to the actual part of the PPA where we provide the goods and services? This can include changes such as adjusting the layout of display racks, providing Braille and raised-character signage, widening doorways, providing visual alarms, and installing ramps.³³ The movie theater, under this section, would want to make sure

that Carlotta could get to the snack bar to purchase her popcorn and into the theater to watch the movie.

Priority Three: Access to Restrooms

The third priority for access is access to the restroom facilities. This may include modifications such as removing obstructing furniture or vending machines, widening doorways, installing ramps, providing accessible signage, widening toilet stalls, lowering paper towel dispensers and mirrors, and installing grab bars, usable faucet handles, and soap dispensers, to name a few. The movie theater would provide Carlotta access to the restrooms under this provision.³³

Priority Four: Access to the Goods and Services

The fourth and final priority for access is access to the goods, services, facilities, privileges, advantages, or accommodations offered at the PPA. This includes access to the actual goods or services that the PPA provides.³⁴ For Carlotta, the PPA needs to consider whether a place exists for Carlotta to sit in the movie theater so that she can watch the movie that she wishes to see. Can they remove seats to provide her a place to sit where she can sit with her family? Can they disperse the seats in the theater so that they do not have to segregate all of the wheelchair users in the back or front of the theater?

- Failing to design and construct new facilities and, when undertaking alterations, alter existing facilities in accordance with the Americans with Disabilities Act Accessibility Guidelines issued by the Architectural and Transportation Barriers Compliance Board and incorporated in the final Department of Justice Title III regulations or the 2010 Standards, depending on the date of completion of the new or altered facilities.^{35,39,40,108} This is where the “building code” flavor of the ADA comes in. Specific requirements dictate how builders should design and decorate buildings to provide access. Readers can find the specifics of these 2010 ADA Standards for Accessible Design (2010 Standards) requirements online at http://www.ada.gov/2010ADASTandards_index.htm.

The government agencies periodically update the accessibility guidelines and related standards. For example, the 2010 Standards allow PPAs to ask individuals to remove their service animal if it is out of control and the handler is not able to get it under control or if it is not house-broken.³² The 2010 Standards also adopt a two-tiered approach to mobility devices by distinguishing wheelchairs and “other power-driven mobility devices” to include mobility devices used by individuals with disabilities but not necessarily developed for that purpose, such as a Segway PT.¹⁰⁷ Wounded soldiers returning from war often use adapted Segway PTs for mobility. The new rules allow access for these alternative mobility devices. Another change in the 2010 Standards provides that places of lodgings must allow individuals to make reservations for accessible guest rooms during the same hours and in the same manner as people without disabilities.¹⁰⁷

Readers should keep in mind that some state regulations differ from the 2010 Standards requirements. For example, Florida requires accessible parking spaces to have a 12-foot width (144 inches) and a 5-foot access aisle,⁹⁹ whereas the 2010 Standards require a width of 8 feet (96 inches) with a 5-foot access aisle.⁷⁶ The ADA regulations advise PPAs to follow the rule that provides the most access to individuals with disabilities.

The Role of the Occupational Therapist

Even though Congress passed the ADA more than 20 years ago, many examples point to a pervasive lack of compliance with access requirements.^{83,94} OTs are in a unique position to promote Title III’s access and inclusion mandates. With our knowledge of performance in areas of occupation, performance skills, performance patterns, activity demands in context, and client factors, we have the skills to look at how the physical environment can affect performance. We know how to make adaptations in the environment, the task, or the person to enable performance despite the limitations that an individual may have in performance skills. This knowledge base equips OTs to help PPAs comply with Title III’s access requirement as consultants by looking at

limitations to accessibility and making recommendations to PPAs to improve access, physical and nonphysical (including attitudes, policies, and procedures).

OTs may find themselves working from two angles in providing access intervention. Their clients may include individuals with disabilities seeking to increase their participation in the community through increasing their access and inclusion, such as Carlotta is. Alternatively, OTs may find that their clients include proactive PPAs seeking to make their goods and services accessible to individuals with disabilities to avoid lawsuits and/or do the right thing.

In the case in which the individual with the disability serves as the client, the OT will want to perform an occupational profile that will delve into the client’s interests in the community, as was done with Carlotta. The OT works with the client to determine what the barriers are to the client’s participation in the community activities of his or her choice. In Carlotta’s case, we know that movies and going to the mall are important to her. Part of our intervention plan will include problem-solving the changes that Carlotta will need to be able to participate in these occupations, explaining her right to accommodations under Title III, and suggesting ways to advocate for the needed changes by the PPA. If the PPA fails to make changes to provide access for Carlotta, she can file an administrative complaint with the Department of Justice in Washington* or immediately file a lawsuit. The OT may serve as a witness in Title III litigation should it come to that.

Under circumstances in which the PPA is his or her client, the OT will look at the goods and services that the PPA offers, the policies and procedures that it uses (especially customer service–related policies), and the physical access offered in the ADA-delineated priority order. Just as an employment-related ADA consultation with an employer usually begins with a job analysis, an access consultation with a PPA begins with an accessibility audit. An accessibility audit is a review of the access and inclusion practices of a PPA from a physical and policy perspective. The accessibility audit looks at the 2010 Standards requirements, the types of modifications that one can make to increase access, and readily achievable changes that one can make according to the priorities set in Title III. Figure 15-1 presents an accessibility audit that includes examining physical as well as nonphysical barriers to access according to the 2010 Standards and follows the priorities specified in Title III. OTs can also provide consultation services for employers.

Air Carrier Access Act

Carlotta’s occupational profile shows that travel is a meaningful occupation for her. To pursue that occupation now that she uses a wheelchair for mobility, she will need to know what to expect while traveling and how she can

*See http://www.usdoj.gov/crt/ada/enforce.htm#anchor_218282.

 **OT Practice Notes****Advocating for Employees with Disabilities**

- Analyze physical functions to determine, for the employee, whether he or she can perform the essential functions of a given job with or without reasonable accommodations.
- Suggest specific reasonable accommodations, such as adaptive equipment, auxiliary aids, or modifications to the worksite, to enable the prospective or returning employee to perform the essential functions of his or her job.
- Obtain adaptive devices or auxiliary aids to facilitate performance in the workplace and in the community.
- Develop strategies to prepare the prospective employee to suggest reasonable accommodations to human resources personnel during the interview and hiring process.
- Teach adolescents with disabilities entering the job market for the first time how to manage the application, hiring, and interview processes.
- Expand access to public accommodations in the mainstream of independent living, such as theaters, conference centers, hotels, and restaurants, through focusing on mobility in the community; identification of equipment, aids, and services; and advocacy to obtain them.
- Provide information to clients so they can develop a basic understanding of what their rights are under the ADA.

 **OT Practice Notes****Consulting with Places of Public Accommodation**

- Advise businesses that offer public accommodations, such as restaurants, movie theaters, hospitals, medical clinics, and hotels, how to make their facilities accessible to individuals with disabilities.
- Ensure that places of public accommodations are accessible to individuals with disabilities and make recommendations to remove architectural and other barriers.
- Assist in the acquisition of auxiliary aids to allow individuals with disabilities to have an equal opportunity to participate in or benefit from programs offered.
- Prevent lawsuits by performing accessibility audits and making recommendations for increased access and barrier removal on a proactive basis.
- Locate and/or acquire auxiliary aids and services for places of public accommodation.
- Train employees in how to make people with disabilities feel welcome in their facilities, how to use the auxiliary aids, and how to provide auxiliary services to individuals with disabilities.

 **OT Practice Notes****Consulting with Employers**

- Analyze jobs to determine essential job functions and possible accommodations that one can easily make for a specific job.
- Develop or rewrite job descriptions based on job analysis that include specific descriptions of essential job functions.
- Modify job sites to make reasonable accommodations for individual employees with disabilities.
- Suggest specific devices and adaptive equipment that allow the employer to hire an individual with a disability who with the assistance of the device, can now perform the essential functions of a given job.
- Sensitize coworkers and supervisors to interacting, supervising, and working effectively with individuals with disabilities.
- Train supervisors to develop reasonable accommodations for injured workers returning to the job, including worker's compensation claimants.
- Ensure that job sites are accessible to individuals with disabilities and make recommendations to remove architectural barriers when inaccessible features are found.
- Propose post-offer, job-related employee screenings and/or evaluations for positions associated with high risk for injury.
- Perform an individualized assessment of a worker's present ability to safely perform the essential functions of the job to determine whether the worker with a disability poses a direct threat to the health and safety of himself, herself, or others.
- Save businesses money by promoting cost-effective reasonable accommodations during the complaint or mediation process to avoid costly litigation.

advocate for herself. The key is the Air Carrier Access Act of 1986 (ACAA). The ACAA, as amended,⁷⁷ prohibits discrimination against qualified individuals with physical or mental impairments in air transportation by foreign and domestic air carriers. The ACAA applies only to air carriers that provide regularly scheduled services for hire to the public. As with the ADA and Fair Housing Act, the ACAA lists specific actions that it considers discriminatory.

Discrimination Prohibited under the ACAA

Airline carriers may not refuse to transport qualified individuals with disabilities on the basis of their disability.³ The definitions of disability are similar to the definitions found in the ADA. A qualified individual with a disability in the airline travel context means that he or she seeks to purchase or has a ticket to fly. The ACAA would protect Carlotta because she has arthritis and an airline ticket. By federal statute, carriers may exclude anyone from a flight if carrying

How To Do An Accessibility Audit Under The ADA

A. Remember, Title III, Public Accommodations, is not limited to the physical accessibility of a building. Title III includes meaningful access and equal participation in all programs and services offered by the public accommodation.

1. Making something accessible is worthless if you do not identify its location. For example, public accommodations must include accessible signage to assist individuals in locating accessible bathrooms and building entrances.

B. Title III sets forth the following priorities for accessibility:

1. **Access to and into the place of public accommodation** from public sidewalks, parking, or public transportation. This includes installing a ramp to the entrance, widening entrances, and providing accessible parking spaces.

2. **Access to those areas of public accommodation where goods and services are made available to the public.** This includes adjusting the layout of display racks, providing Brailled and raised character signage, widening doorways, providing visual alarms, and installing ramps.

3. **Access to restroom facilities.** This includes removing obstructing furniture or vending machines, widening doorways, installing ramps, providing accessible signage, widening toilet stalls, lowering paper towel dispensers and mirrors, and installing grab bars.

4. **Access to the goods, services, facilities, privileges, advantages, or accommodations offered at the place of public accommodation.** This includes access to the actual goods or services themselves.

C. The Accessibility Audit should follow the priorities set forth in Title III.

STEP ONE: According to the first priority, look at the access to and into the place of public accommodation from public sidewalks, parking, or public transportation:

	YES	NO
1. Are parking spaces 96 inches wide with an adjacent access aisle of 60 inches?	_____	_____
2. Is one in every eight parking spaces served by a 96-inch access aisle marked "van accessible?"	_____	_____
3. How many parking spaces are designated for individuals with disabilities? _____ (_____% of spaces) (compare with chart at ADAAG § 4.1.2(5)(a); 10% of total number provided for outpatient units or facilities should be accessible.)	_____	_____
4. If covered parking is provided, is the ceiling at least 114 inches high to allow access to high-top vans?	_____	_____
5. Are all curb ramps (curb cuts) from the parking spaces at a gradient of 1:20 with a textured, non-slip surface?	_____	_____

FIGURE 15-1 How to do an accessibility audit under the ADA.¹⁰⁸
(Courtesy Barbara L. Kornblau, ADA Consultants, Inc., 1992, 2002, 2011.)

- | | | | |
|-----|---|-------|-------|
| 6. | Are parking area and building separated by a street? | _____ | _____ |
| 7. | Are the accessible parking spaces located on the shortest accessible route of travel from the parking to the accessible building entrance? | _____ | _____ |
| 8. | Is the surface of the accessible route smooth (no sand, gravel, or utility hole covers)? | _____ | _____ |
| 9. | Are all ramps along the accessible route at a gradient of at least 1:12 (1:16 - 1:20 preferred)? | _____ | _____ |
| 10. | Do ramps have 5-foot level landings at the bottom and top that are as wide as the ramp itself? | _____ | _____ |
| 11. | Do all ramps have handrails with top handrail, non-slip, gripping surfaces mounted between 34 inches and 38 inches above the ramp surface? | _____ | _____ |
| 12. | Is the accessible route walkway at least 48 inches wide? | _____ | _____ |
| 13. | Is the accessible route marked with appropriate signage? | _____ | _____ |
| 14. | Is there a passenger loading and unloading zone? | _____ | _____ |
| 15. | The accessible entrance is located _____
_____ | _____ | _____ |
| 16. | Is the accessible door marked with appropriate signage? | _____ | _____ |
| 17. | Is the entrance door a minimum of 32 inches wide? | _____ | _____ |
| 18. | Is the door automatic? | _____ | _____ |
| 19. | Is the door-opening mechanism set to less than _____ pounds of pressure (as measured by a push than pull scale, although no specific requirements are set for exterior doors at this time)? | _____ | _____ |
| 20. | If there are two doors in series at the entrance, do the doors open in the same direction or away from the space between the two doors and is the space at least 48 inches plus the width of any door opening into the space? | _____ | _____ |
| 21. | Is there an alternative to a revolving door? | _____ | _____ |
| 22. | Is door hardware shaped so as to require one hand to open and not to require tight grasping, tight pinching, or twisting of the wrist to operate? | _____ | _____ |
| 23. | Are thresholds less than ½ inch high? | _____ | _____ |
| 24. | If the primary entrance has steps, is there a proper sign directing patrons to the accessible entrance? | _____ | _____ |

FIGURE 15-1, cont'd

STEP TWO: Look at access to those areas of public accommodation where goods and services are made available to the public. This includes adjusting the layout of display racks, providing Brailled and raised character signage, widening doorways, providing visual alarms, and installing ramps.

A. List all areas in the facility where goods, services, and programs are provided to the public. (Remember, this includes areas in places that are not normally considered places of public accommodations, but parts of those facilities where members of the public would go, i.e., the showroom of a factory not open to the general public but where outside buyers and salespersons might go.)

B. Are all areas where goods, services, and programs are located accessible?
(This section should be repeated for all goods, services, and programs offered at the location.)

Goods/Service/Program and Location

FIGURE 15-1, cont'd

	YES	NO
1. Is the width of the pathway to the area, including corridors and aisles, at least 32 inches of usable space?	_____	_____
2. Is the pathway free of protruding telephones, water fountains, or other items?	_____	_____
3. Is the pathway flooring covered with high-density, low-pile (½ inch) carpeting, non-slip tile, or vinyl?	_____	_____
4. Are doorways at least 32 inches wide?	_____	_____
5. If there are steps along the pathway, is the area also served by an elevator?	_____	_____
6. Are steps covered with non-slip surfaces, provided with adequate lighting, and designed with curved nosers and sloped risers?	_____	_____
7. Do all stairways have handrails positioned at both sides of the stairs with top handrail, non-slip, gripping surfaces mounted between 34 inches and 38 inches above the stair nosing?	_____	_____
8. Do the handrails extend 12 inches beyond the top riser and 12 inches plus the width of one thread beyond the bottom riser?	_____	_____
9. Are thresholds at ½ inch high or less for interior doors?	_____	_____
10. Is the door-opening mechanism set to 5 pounds of pressure or less?	_____	_____
11. Is door hardware shaped so as to require one hand to open and not to require tight grasping, tight pinching, or twisting of the wrist to operate?	_____	_____
12. If doorways have two independently operated door leaves, is one leaf at least 32 inches wide?	_____	_____
13. If there are two doors in series along the pathway, do the doors open in the same direction or away from the space between the two doors and is the space at least 48 inches plus the width of any door opening into the space?	_____	_____
14. Are elevator call buttons centered at 42 inches above the floor and at least ¾ inch in diameter?	_____	_____
15. Do objects mounted below the elevator call button protrude more than 4 inches into the elevator lobby?	_____	_____
16. Are visible and audible signals provided at each elevator entrance to indicate which car is answering the call and the direction the car is going (once for up and twice for down)?	_____	_____

FIGURE 15-1, cont'd

- | | | | |
|-----|--|-------|-------|
| 17. | Are raised and Braille characters at least 2 inches high, provided on both jams of the elevators, and centered 60 inches above the floor? | _____ | _____ |
| 18. | Are elevators provided with an automatic reopening device? | _____ | _____ |
| 19. | Is the minimum amount of time the elevators remain open in response to a call at least 3 seconds? | _____ | _____ |
| 20. | Are control buttons inside the elevator designated by Braille and raised letters? | _____ | _____ |
| 21. | Are floor buttons 54 inches or less above the floor for a side wheelchair approach and 48 inches or less for a front approach? | _____ | _____ |
| 22. | If public telephones are provided, are they on an accessible floor at an accessible location? | _____ | _____ |
| 23. | Is at least one telephone mounted so that its operable parts are no more than 54 inches or less above the floor for a side wheelchair approach and 48 inches or less for a front approach? | _____ | _____ |
| 24. | Is there a clear floor or ground space of at least 30 inches by 48 inches under the telephone absent bases, enclosures, fixed seats, and protruding objects of more than 4 inches? | _____ | _____ |
| 25. | Is at least one telephone equipped with an amplifier for individuals with hearing impairments and located near an electrical outlet for portable TTDs? | _____ | _____ |
| 26. | Is the telephone cord at least 29 inches long? | _____ | _____ |
| 27. | Is at least one text telephone provided? | _____ | _____ |
| 28. | Where are the accessible telephones located? | _____ | _____ |
| 29. | Are accessible telephones marked with appropriate signage? | _____ | _____ |
| 30. | Are water fountains mounted so that spouts are no higher than 36 inches from the floor? | _____ | _____ |
| 31. | Are fire alarms and other warning signals provided in both a visual and audible manner? | _____ | _____ |
| 32. | Are room numbers, directional signs, emergency directions, and other signs and markings indicated in large, block letters and numerals, using contrasting colors so they can be read by individuals with visual impairments? | _____ | _____ |
| 33. | Are signs provided in raised and Braille letters and numbers? | _____ | _____ |

FIGURE 15-1, cont'd

If the answer to any of the above questions is no, what reasonable accommodations may be made to allow access to the area where the goods, services, and programs are provided?

STEP THREE: Look at access to restroom facilities.

	YES	NO
1. Where are the accessible restrooms located? _____ _____	_____	_____
2. Is the accessible restroom designated with appropriate signage?	_____	_____
3. Is the restroom on an accessible pathway?	_____	_____
4. Can one use the restroom without going up or down steps?	_____	_____
5. Is the width of the pathway to the restrooms, including corridors, and aisles, at least 32 inches of usable space?	_____	_____
6. Is the pathway to the restrooms free of protruding telephones, water fountains, or other items?	_____	_____
7. Is the pathway flooring to the restrooms covered with high-density, low-pile (½ inch) carpeting, non-slip tile, or vinyl?	_____	_____
8. Are the doorways to the restrooms at least 32 inches wide?	_____	_____
9. Do doorways to the restroom require 5 pounds or less of pressure to open?	_____	_____
10. Is the entrance to the toilet stall at least 32 inches wide?	_____	_____
11. Is the top of the seat of the accessible toilet between 17 inches and 19 inches from the floor?	_____	_____
12. Does the toilet paper dispenser allow for the continuous flow of toilet paper without delivery control?	_____	_____
13. Does the toilet stall have a minimum depth of 56 inches where toilets are wall mounted and 59 inches where toilets are floor mounted?	_____	_____
14. Is at least one stall a minimum of 36 inches wide with an outwardly opening, self-closing door?	_____	_____

FIGURE 15-1, cont'd

- | | | | |
|-----|--|-------|-------|
| 15. | Are there a minimum of two grab bars at least 36 inches long in the accessible toilet stall with one grab bar mounted behind the toilet? | _____ | _____ |
| 16. | Are grab bars between 33 inches and 36 inches from the floor? | _____ | _____ |
| 17. | Are urinal rims at a maximum of 17 inches from the floor? | _____ | _____ |
| 18. | Is there a clear space in front of the urinal of 30 inches by 48 inches to allow a front approach? | _____ | _____ |
| 19. | Are soap dispensers, paper towel dispensers, hand dryer, and feminine product dispensers within 48 inches from the floor? | _____ | _____ |
| 20. | Are mirrors mounted so that the bottom edge is within 40 inches from the floor? | _____ | _____ |
| 21. | Are sinks mounted so that the rim or counter surface is within 34 inches of the floor and a 29-inch clearance space is provided from the floor to the bottom of the apron? | _____ | _____ |
| 22. | Is there a clear space in front of the sink of 30 inches by 48 inches to allow a front approach? | _____ | _____ |
| 23. | Are hot water pipes insulated or configured to avoid contact? | _____ | _____ |
| 24. | Are sink faucets lever-operated, push-type, electronically controlled, or otherwise operable with one hand without requiring tight grasping, pinching, or twisting of the wrist? | _____ | _____ |
| 25. | Do self-closing faucets remain open for at least 10 seconds? | _____ | _____ |

STEP FOUR: Look at access to the goods, services, facilities, privileges, advantages, or accommodations offered at the place of public accommodation.

This step answers the question, “Can people use or take advantage of the goods, services, facilities, or programs provided at the place of public accommodation?”

Look back at the goods, services, facilities, or programs identified in **STEP TWO** and determine whether they are usable. **For example:**

- | | | YES | NO |
|----|---|-------|-------|
| 1. | Are printed materials provided in alternative formats where needed? | _____ | _____ |
| 2. | Are items in racks or on walls within reach? | _____ | _____ |
| 3. | Are special listening devices provided for individuals with hearing impairments in theaters, conference centers, and concert halls? | _____ | _____ |

FIGURE 15-1, cont'd

- | | | | |
|----|--|-------|-------|
| 4. | Can individuals in wheelchairs reach the microfilm machines at the library? | _____ | _____ |
| 5. | Is there an integrated location for individuals in wheelchairs to sit at the football stadium without having to transfer out of one's chair? | _____ | _____ |
| 6. | Can individuals with disabilities reach the items on the grocery store shelves? | _____ | _____ |

STEP FIVE: If STEPS ONE through FOUR identify goods, services, facilities, or programs that are not usable by individuals with disabilities, can an accommodation be made to enable the individual to take advantage of the goods, services, facilities, or programs?

Are there policies that need to be changed to enable participation by individuals with disabilities?

FIGURE 15-1, cont'd

the person would pose a direct threat to the health and safety of others.⁴ This parallels the direct threat criteria under the ADA. If the airline carrier excludes persons with disabilities on safety grounds, the carrier must provide a written explanation of the decision within 10 days of the refusal, including the specific basis for the refusal.⁶

Airline carriers may not deny transportation to a qualified individual with a disability “because the person’s disability results in appearance or involuntary behavior that may offend, annoy, or inconvenience crewmembers or other passengers.”⁵ Airline carriers cannot limit the number of people with disabilities that it will allow on a flight as a means of refusing transportation based on disability.² The ACAA prohibits airlines from requiring a person with a disability to accept special services, such as preboarding, if the passenger does not request them.¹ Similarly, air carriers cannot segregate passengers with disabilities even if separate or different services are available to them.⁸

Under the ACAA, airline carriers cannot require qualified individuals with a disability to provide advance notice of their intention to travel or of their disability as a condition of receiving transportation or of receiving services or required accommodations.⁷ Carlotta would not have to notify the airline in advance that she planned to fly. A limited exception to this rule exists, however. An airline carrier may require up to 48 hours’ notice for certain specific accommodations that require advance preparation. These include, for example, medical oxygen use,

transportation of an electric wheelchair in a plane with fewer than 60 seats, travel with a service animal on a flight longer than 8 hours or an emotional support or psychiatric service animal, and provision of an on-board wheelchair in an aircraft that lacks an accessible lavatory.⁸

Airlines cannot exclude a passenger with disabilities from a particular seat or require him or her to sit in a certain seat, except to comply with FAA safety regulations such as exit row seating, which requires passengers have specific abilities to open the exit door in case of an emergency.¹⁵ Airlines must accommodate passenger seat assignments if required based on the person’s disability and requested 24 hours in advance. For example, if Carlotta traveled with a service animal that assisted her in tasks such as pulling her wheelchair and picking up items from the floor, the carrier would have to assign them to a bulkhead seat or another seat that could accommodate the service animal.¹⁴

Airline carriers may not require a person with a disability to travel with an attendant, except in certain limited circumstances.⁹ Such limited circumstances include, among others, those in which a person with an impairment in mobility is unable to assist in his or her own evacuation and in which a person with a mental disability cannot understand or respond to the crew’s safety instructions.⁹ If the person with a disability and the carrier disagree about whether the individual’s circumstances meet the ACAA’s criteria, the carrier may require the attendant but may not charge for the attendant’s transportation cost.⁹

■ Box 15-9

Services Airlines Must Provide If Requested

- Assistance moving to and from seats during boarding and deplaning
- Assistance in preparation for eating, such as opening cartons (but not assistance in eating)
- Assistance to and from the lavatory if the aircraft has an on-board wheelchair (but no assistance in the lavatory)
- Assistance moving to and from the lavatory for a semi-ambulatory person, not involving lifting or carrying
- Assistance loading and retrieving carry-on items, including mobility aids stored on board

Air Carriers' Obligations

Airline carriers must provide assistance in boarding and deplaning by providing personnel, ground wheelchairs, boarding wheelchairs, and ramps or mechanical lifts.¹⁶ If entry-level boarding is unavailable, airlines must provide boarding assistance through lifts or ramps.¹⁷ Exceptions exist for certain small airplanes and low-volume airports. OTs should review with Carlotta how to explain to airline personnel the safest way to transfer her. Carlotta should also know that the carrier cannot leave her unattended in a ground or boarding wheelchair for more than 30 minutes if she cannot independently operate that wheelchair.¹⁸ The carrier must also accept her wheelchair as carry-on baggage if a place exists to store it on the plane or as gate-checked baggage, which the airline returns to her as soon as possible and as close to the airplane door as possible if she wishes.²⁰ She can also choose to have it delivered to her in the baggage claim area.²⁰

The ACAA requires airlines to provide other assistance to individuals with disabilities as outlined in Box 15-9.¹⁹ Carriers cannot charge for providing these services.¹⁰

Wide-bodied aircraft must have accessible lavatories, and those with 100 seats or more must have priority space for storing wheelchairs in the cabins.^{12,13} This information may help Carlotta select her flights based on the services that the plane provides. In addition to services and access on the airplanes themselves, airlines must make sure that their terminals are accessible.¹¹

The ACAA requires airline carriers to train their employees in awareness and appropriate response to persons with a disability, “including persons with physical, sensory, mental, and emotional disabilities, including how to distinguish among the differing abilities of individuals with a disability.”²¹ This could provide opportunities for advocating for a particular client such as Carlotta or for consulting with the airline to provide sensitivity training and disability awareness.

Each airline must designate a complaint resolution official at each airport that it serves to receive and make efforts to resolve complaints. If it cannot resolve the complaint, it

must give the passenger a written summary of the problem and outline the steps that the carrier will take to solve it. It must also notify the passenger of his or her right to pursue the complaint with the U.S. Department of Transportation (DOT).²² Passengers may refer to <http://airconsumer.ost.dot.gov/ACAAComplaint.htm> for information about filing a complaint with the DOT.

The DOT takes the ACAA very seriously. In February, 2011, one airline agreed to a \$2 million settlement with the DOT for failing to provide adequate and prompt enplaning and deplaning wheelchair assistance to passengers with disabilities, failing to provide dispositive responses to written complaints alleging ACAA violations, and failing to properly categorize and accurately report its disability-related complaints.⁷⁵

Role of the Occupational Therapist

OTs can work with their clients to understand what their needs will be for air travel and help them develop a strategy to follow to meet their needs. They can also play a key role in informing clients of the rights to which they are entitled in air travel and how to advocate for those rights for themselves.

Ethical Considerations

As OTs we are in a unique position to facilitate an understanding of disabilities and the impact that disabilities play on everyday activities and functions. OTs can use this knowledge to work directly with airlines as consultants and conduct the training mandated by law to promote a culture of sensitivity and awareness.

Fair Housing Act

Congress passed the Fair Housing Amendments Act of 1988 to add “handicaps” (hereafter referred to as individuals with disabilities, a more politically correct term with the same legal meaning⁸⁷) to the list of those protected against discrimination in housing. Before passage of the Fair Housing Act Amendments, the Fair Housing Act (FHA) prohibited discrimination based only on race, color, religion, sex, handicap, familial status, or national origin.⁹²

Generally, the FHA prohibits discrimination in the sale, rental, or advertising of housing dwellings, in the provision of brokerage services, or in other residential real estate-related transactions such as the provision of mortgage loans. The FHA covers private housing, housing that receives federal government assistance, and state and local government housing. Some exceptions exist to the FHA. For example, the FHA does not apply to owner-occupied apartment buildings with four or fewer units or private homes in which the owner owns fewer than three single-family homes and is not in the business of selling or renting dwellings.

The FHA defines individuals with disabilities with the same definition as the one found in the ADA. Discrimination means denying or making a sale or rental unavailable because of the disability of a buyer or renter, the disability of an intended resident, or the disability of any person associated with a person with a disability. Landlords may not inquire whether the applicant for sale or rental of housing is an individual with a disability, and they cannot charge a higher price or provide different services because a renter or purchaser of a dwelling unit is an individual with a disability.

Passage of the Fair Housing Act Amendments gave individuals with disabilities certain additional rights to use and enjoy their dwellings. These additional rights play a significant role in promoting independent living and participation for individuals with disabilities. Under the FHA it is illegal to refuse to permit reasonable modification of existing premises occupied or to be occupied by individuals with disabilities if the proposed modification is necessary to allow the person with the disability full use and enjoyment of the dwelling. Unlike the ADA, where businesses have to pay for the modifications that provide access, the FHA does not require landlords to pay for the modifications. It requires only that the landlord allow the tenant to make modifications at the expense of the person with a disability who needs those modifications.

The landlord may, if reasonable, condition permission for modification on the renter agreeing to restore the interior to its condition before the modification. If the renter plans to make a modification in the dwelling, the landlord may not increase a security deposit. The landlord may, however, condition permission for modification on provision of a reasonable description of the proposed modification and assurances that the work will be properly performed by licensed professional with permits, as well as other stipulations.

The FHA also makes it illegal for any person to refuse to make reasonable accommodations in rules, policies, practices, or services when needed to afford a person with a disability equal opportunity to use and enjoy a dwelling unit, including public and common use areas. For example, an apartment building management company would have to make an exception to a “no pets” policy so that an individual with a spinal cord injury could keep a service dog. Another often-disputed example involves parking. A person with a disability may need an assigned parking space close to his or her apartment in a development that prides itself on unassigned parking. It would be a reasonable accommodation to modify the parking policy to allow assignment of a parking space to the person with the disability.

Research shows that intervention based on home assessments, such as providing bath benches and recommending grab bars, helps prevent falls in the home and encourages safe and independent participation in everyday home life.^{85,101} Part of Carlotta’s intervention plan would include a home assessment. Applying the provisions of the FHA to

Carlotta affords her some assistance in her quest for independent participation. First, the landlord would have to allow Carlotta to install the grab bars that her OT recommended for her bathtub, as long as this was done in a workman-like manner with permits and all necessary requirements. The landlord would probably have to allow Carlotta to widen her bathroom door as the OT recommended so that Carlotta could wheel her wheelchair into the bathroom. With these modifications and others developed by the OT in collaboration with Carlotta, Carlotta can independently participate in her ADLs.

The second issue for Carlotta involves her need for assistance to carry out her aquatics home program. To do this, she must be able to use the pool, an amenity to which she is entitled like all residents of the apartment complex. Carlotta has no access to the pool unless her friend can help her get in and out of the pool each day. The landlord would probably have to modify the “no guests in the pool on weekends” policy to allow Carlotta access to and use of the pool on weekends.

What if the landlord does not want to allow Carlotta to make these accommodations? Even the most wonderful suggestions for accommodation that the OT and/or OTA makes are worthless if the client cannot use them. Because the success of the occupational therapy intervention plan may rest on provision of these accommodations, the OT and/or OTA will want to steer Carlotta to the Website for the U.S. Department of Housing and Urban Development (HUD).^{*} At this Website Carlotta can file an administrative complaint to encourage the landlord to allow her to make the needed accommodations. Remember that under the FHA the landlord is not responsible for making the accommodations but must allow the tenant to make needed reasonable accommodations. HUD staff will contact the landlord and/or property management company, mediate the situation by encouraging them to follow the law, and try to resolve the issues without the necessity of filing a lawsuit.

OTs and OTAs will also find the FHA helpful in other very commonly encountered situations. For example, OTs who make home visits to patients’ and clients’ homes before hospital discharge will appreciate the support of the FHA. During these home visits, OTs customarily evaluate the individual’s ability to function in the home as independently as possible. This assessment includes making recommendations about adaptive equipment and other modifications to the home to promote independent participation. The FHA gives the therapist’s recommendations clout should the landlord refuse to allow the modifications to the dwelling unit. Clients in need of grab bars and other accommodations in their homes have an alternative route to take should the landlord say “no” to the accommodations needed.

^{*}<http://www.hud.gov/complaints/housediscrim.cfm>

Advocacy as Intervention

OTs promote participation in work, leisure, and ADLs. As shown earlier, sometimes barriers to participation exist despite the efforts of OTs with their clients. For example, the client successfully transfers from the wheelchair to the toilet and bath bench in the clinic but cannot get into the bathroom at home if the landlord will not allow modifications to the apartment. Carlotta can do her job from a wheelchair, but the headmaster will not transfer her to an accessible classroom.

To promote participation in these instances, the OT may have to include advocacy as an intervention strategy. The OT may need to act as an advocate, or he or she may have to guide the client through a self-advocacy process.

Ethical Considerations Eight Rules of Advocacy

- Know your laws.
- Read the regulations.
- Believe that you or your client has a right to what you seek.
- Organize yourself, document your efforts, get everything in writing, and keep copies of all correspondence.
- Start with the source of the problem.
- Be specific; tell them exactly what you want.
- File a complaint with the administrative agency that oversees the matter.
- Follow through.

Summary

The ADA, ACAA, and FHA exist to provide individuals with disabilities certain rights. These laws, in concert with occupational therapy intervention, have the potential to open many avenues to participation for individuals with disabilities. By familiarizing themselves with these laws and sharing that information with clients, OTs can play a major role in ensuring that those whom they serve have more opportunities to participate in work, leisure, and ADLs.

With the assistance of the ADA, ACAA, and, FHA, Carlotta should be able to continue in her job as a teacher with the reasonable accommodations provided by her employer under Title I of the ADA. Carlotta can continue traveling by airplane to find the perfect bed and breakfast with accommodations provided to her under the ACAA. She can continue shopping and going to movies with the protection afforded to her under Title III of the ADA. The FHA will provide the tools that Carlotta needs to stay in her current apartment and care for herself independently and with cooperation from her landlord for the accommodations that she needs.

Leisure Occupations

SHEAMA KRISHNAGIRI
MARTI SOUTHAM

■ Chapter Outline

Leisure and life satisfaction for persons with physical disabilities

Benefits of play and laughter in leisure occupations

Meaningful leisure occupations: age, cultural issues, and gender

Age and leisure

Young adulthood (20 to 40 years)

Middle adulthood (40 to 65 years)

Late adulthood (65 years and older)

Culture and leisure

Leisure occupations related to culture

Leisure-time physical activity by gender, age, and racial/ethnic groups

Leisure occupations: evaluation and intervention

Intervention: where there's a will, there's a way

Adapting the activity for success

Level of functioning

Summary

Review questions

■ Key Terms

Leisure

Play

Humor

Modeling

Leisure exploration

Leisure participation

■ Learning Objectives *After studying this chapter, the student or practitioner will be able to do the following:*

1. Discuss the benefits of leisure for adults.
2. Describe the key areas in which humor can be used.
3. Understand the differing needs that people in different stages of life have.
4. Identify specific strategies to promote leisure activity for persons with disabilities.

Threaded Case Study | Jeri, Part 1

Before a traffic accident, Jeri, a 29-year-old newly married woman, lived a full and happy life. She was employed as an interior designer; spent time with her husband, friends, and family; and participated in leisure occupations. She particularly enjoyed scrapbooking, going to a nearby lake to boat and fish, playing with and caring for her dogs, and shopping. As Jeri was driving home from running errands one evening, a drunk driver hit her car. It rolled over and she was trapped inside. After being removed from the car and taken by paramedics to the local hospital, she was found to have a traumatic brain injury, a broken wrist, and a broken leg. Jeri was transported to the regional brain trauma center for rehabilitation. She recovered over a period of months and returned home.

Jeri continues rehabilitation as an outpatient for residual problems from her brain injury, as well as for continuing problems using her dominant hand because of the wrist fracture. Jeri receives occupational therapy twice weekly and is demonstrating significant improvement; she progressed from

needing maximum assistance for activities of daily living (ADLs) to minimum assistance. Jeri has no apparent cognitive deficits, uses a walker to ambulate, and still needs a family member or aide at home on a full-time basis because of poor balance, which impairs her safety when moving around in her environment. The occupational therapist is ready to discharge Jeri because her ADL goals have been met. During the intervention review before discharge, Jeri reports that she spends most of her days hanging out at home watching TV, feels lonely and disengaged from her friends, and will miss occupational therapy because it is her only activity outside the home.

Critical Thinking Questions

1. Is Jeri ready to be discharged from occupational therapy?
2. Why is Jeri dissatisfied with her current lifestyle?
3. What intervention could the occupational therapist provide to improve Jeri's quality of life?

Participating in meaningful leisure occupations is vital to a healthy, balanced lifestyle.^{6,41,50} As an area of occupation, leisure is defined in the Occupational Therapy Practice Framework as “a nonobligatory activity that is intrinsically motivated and engaged in during discretionary time, that is, time not committed to obligatory occupations such as work, self-care, or sleep”⁴⁶ (p. 632). Key phrases in the definition are that these activities are intrinsically motivated and that they are not obligatory. In other words, people participate in leisure occupations that they choose and enjoy. For instance, for some people cooking could be a chore, whereas for others it is a joyful pleasure.

Leisure time may be spent in a variety of ways indicative of an individual's unique interests. Examples of leisure occupations are reading, playing games, participating in sports, doing arts and crafts, engaging in outdoor activities (biking, hiking, fishing), cooking, taking a yoga class, exercising at the gym, going to concerts, watching movies, and so on. Because of the uniqueness of individuals, this list is as long as there are people who participate in leisure occupations.

Leisure and Life Satisfaction for Persons with Physical Disabilities

When adults sustain injuries (e.g., traumatic brain injury, stroke, spinal cord injury, carpal tunnel syndrome), have health conditions (e.g., multiple sclerosis, Parkinson's disease, arthritis), or experience life transitions (e.g., empty nest syndrome, menopause, retirement) that disrupt normal habits and routines, they face devastating losses. Loss of work, social activities, and meaningful leisure activities may contribute to depression, and the self must be redefined.⁶⁴

Occupational therapists are skilled in collaborating with people with physical disabilities to assist them in resuming a full life.⁶² It has been suggested that one method of measuring whether a person is fully engaged in life is to consider the individual's participation in leisure activities.^{11,51} This is especially important because research indicates that the perception of leisure satisfaction by adults with physical disabilities is the most significant predictor of life satisfaction.^{31,33} Depressive symptoms have also been shown to decrease when the number and variety of pleasant activities increase.^{18,25,56} Engaging in leisure activities provides a receptive environment for opportunities for socialization and friendship making in which people with physical disabilities have a chance to demonstrate their occupational skills to others who might not otherwise view those with a disability as being capable or as a friendship candidate.⁵³

Additionally, leisure has been shown to contribute to individual development and well-being and provides a significant mechanism of coping.^{46,65,66}

Sadly, however, studies indicate that most leisure activities are abandoned after the onset of a physical disorder such as rheumatoid arthritis or stroke.^{51,69} Adults with physical disabilities seem to relinquish activities that are purely for enjoyment, especially community-based social activities, and focus their effort and time on activities of daily living and work.⁵¹ The emphasis on the physical model of recovery is most likely due to (1) health professionals who deliver treatment with a focus on mobility and independence in activities of daily living and (2) the fact that rehabilitation outcome measures are commonly based on these factors.⁵¹ Occupational therapists need to recognize that people often experience difficulty adapting their interests and activities by themselves after a physical or neurological disorder.

 OT Practice Notes

Benefits of Leisure Activities

Participation in leisure activities can offer many psychosocial and physical benefits, such as the following:

Psychosocial Benefits

- Increased sense of self-worth
- Release of hostility and aggression
- Shared control of self and environment
- Experience of choice
- Increased socialization
- Development of leadership
- Practice in adaptive behavior and coping skills
- Increased attention span
- Adjustment to living arrangements
- Increased tolerance of groups and other people
- Experience of intellectual stimulation

Physical Benefits

- Increased circulation
- Promotion of gross, fine, bilateral, and eye-hand coordination
- Provision of vestibular stimulation
- Provision of sensory stimulation
- Promotion of motor planning
- Improvement or maintenance of perceptual abilities
- Maintenance or improvement of adaptive and coping skills
- Increased strength, range of motion, and physical tolerance
- Improved balance
- Provision of opportunity to grade activities

 OT Practice Notes

The Therapist's Role in Encouraging Leisure Activities

If therapists provide interventions aimed only at physical rehabilitation (e.g., strengthening, range-of-motion exercises) and improving performance in activities of daily living and instrumental activities of daily living, the recovering individual may never experience the opportunity of resuming old leisure interests or developing new ones. Leisure skills are integral to redefining one's identity, self-worth, and self-efficacy.

A randomized, controlled study of stroke survivors supports the need for occupational therapists to address the leisure area of occupation for clients to engage in leisure interests and activities after therapy is discontinued.¹⁸ Sixty-five clients were randomly assigned to three groups: leisure rehabilitation, conventional occupational therapy treatment, and control. The baseline number and frequency of leisure activities in the three groups demonstrated no significant difference between the groups on admission to the hospital.

After discharge from the hospital, the leisure rehabilitation group and the conventional occupational therapy group were treated by the same occupational therapist for 30 minutes one time per week for 3 months and then one 30-minute session every 2 weeks for 3 months. Each person in the leisure rehabilitation group was given an individualized program that included “advice and help ... in the following broad categories: treatment (e.g., practice of transfers needed for leisure pursuits); positioning; provision of equipment; adaptations; advice on obtaining financial assistance and transportation; liaison with specialist organization, and providing physical assistance (e.g., referral to voluntary agencies).”¹⁸

The occupational therapy group received individualized treatment by the same therapist for the same amount of time. Interventions included “transfers, washing and dressing practice, and, where appropriate, perceptual treatments. ... No reference was made to the importance of continuing previous interests, and no help or advice was offered to encourage participation in leisure pursuits”¹⁸ (p. 285). At 3 and 6 months after discharge, an independent assessor readministered the leisure questionnaire, which showed that the leisure rehabilitation group had significantly higher leisure scores than did the conventional occupational therapy group and the control group.¹⁸

Thus, adults with physical disabilities may give up leisure activities because they are not aware of ways to adapt valued activities so that they may participate in them again, or they may not know about new hobbies or crafts that they might enjoy. Occupational therapists have an important role in helping people both explore and plan engagement in leisure occupations so that they may participate in activities that bring joy to life.^{12,62,64} Engagement in serious leisure (term used in the literature to indicate fulfilling leisure activities that engage the individual's special skills, knowledge and experience) has been positively associated with positive affect.³¹

Benefits of Play and Laughter in Leisure Occupations

When talking about participating in leisure occupations, people often use the word *play*. Some examples are to play golf, play the piano, play sports, play cards, play board games, and so on. Play allows adults to escape the reality of everyday life and immerse themselves in a world of carefree spontaneity that provides meaning to their existence. Play suggests fun, and fun is often accompanied by laughter.

Many physical health benefits of laughter have been demonstrated through numerous research studies. For example, immune cells increase and stress hormones decrease, thereby possibly preventing illness or helping in recovery.^{10,54,63} Some people experience relief from pain and a sense of well-being after hearty laughter.^{1,17} Laughter also benefits people psychologically and psychosocially.^{19,57,60,68}

Box 16-1

Health Benefits of Laughter

Physical Health Benefits of Laughter^{19,57}

- Stress hormones (e.g., cortisol and noradrenaline) decrease¹⁰
- Immune functions increase (e.g., immunoglobulin A and natural killer cells)^{10,63}
- Muscle tension relaxes
- Blood pressure drops and cardiovascular functions improve; increases blood flow to aid healing
- Respiratory airways are cleared (through laughing and coughing)
- Pain relief may be attained after hearty laughter and last for several hours because of release of opioids and endorphins⁵⁴
- “Feel good” hormones (e.g., β -endorphins and serotonin) are released

Psychological and Psychosocial Health Benefits of Laughter^{57,60}

- Facilitates bonding—laughter occurs more often with others than when alone
- Improves coping with problems¹
- Increases well-being and promotes hope and optimism³⁸
- Diverts negative thoughts—it is hard to maintain destructive thoughts when laughing¹⁷
- “Saves face” in embarrassing situations
- Facilitates mental clarity, creativity, and brainstorming because the two hemispheres communicate better during humor and the limbic system is aroused³⁸
- Adds vibrancy to facial tone and sparkle to the eyes

Laughing together facilitates bonding, reduces anxiety, and improves coping^{27,38}—all important factors in a therapeutic alliance between the occupational therapist and client (Box 16-1).

Facilitating psychosocial and physical adaptations is integral to occupational therapy, and given the current health care climate of high productivity and short hospital and rehabilitation stay, it is imperative that occupational therapists be able to quickly form a therapeutic alliance with their clients. Humor and laughter are natural ways that therapists and clients connect. Recent studies have found that all of the occupational therapists who were interviewed or surveyed agreed that humor has a place in occupational therapy.^{35,40,60,67}

In a national cross-sectional randomized survey of 283 occupational therapists that examined their attitudes and use of humor in interacting with adult clients with physical disabilities, humor was classified into four key areas: (1) building relationships, (2) helping clients cope with adversity, (3) promoting clients’ physical health, and (4) facilitating compliance with treatment.⁶⁰ Although therapists reported positive attitudes about humor in all four of these areas, most were actually using humor only to build relationships and to help clients cope. The majority of

therapists felt comfortable using spontaneous humor with clients as part of the therapeutic use of self rather than using planned humor as a therapeutic intervention.

People who are disabled may need to learn ways to adapt to their new circumstances. Humor is a skill that can be learned and may provide the client with the ability to manage concerns related to his or her health and life situations. Within a larger relational context, humor may be modeled by occupational therapists to teach coping skills. Bandura described four essential factors for modeling to be an effective intervention.⁷ First, the client must have adequate attention span to focus on the modeled behavior. Second, he or she must be able to cognitively form and retain a mental image of the behavior. Third, the client must be able to recall the image and then produce the behavior. Last and perhaps most important, the client must have the motivation to engage in the behavior.

Ethical Considerations

Establishment of trust through the bond of a therapeutic relationship may provide the encouragement that clients need to try new behavior such as humor and laughter.³⁰

The intimacy that humor presumes may provide the client with a sense of connection with the therapist. This connection, which occurs on conscious and unconscious levels, has many positive benefits for clients. When the therapist is able to demonstrate professionalism and empathy with a touch of humor, a client may feel less alone and more cared for as an individual.^{26,60} An improved sense of equality with the health care provider may occur that could increase the client’s active involvement in her or his treatment.^{2,19}

Although laughter has been shown to be beneficial, there are times when humor may not be a good choice and must be used with caution or avoided altogether. Seizures and cataleptic or narcoleptic attacks may follow a laughter episode in a small number of people.²⁴ In addition, because laughing increases abdominal and thoracic pressure, people with recent abdominal surgery, upper body fractures, acute asthma, or “preexisting arterial hypertension and cerebral vascular fragility”²⁴ (p. 1857) should not be encouraged to laugh.

Ethical Considerations

Occupational therapists also need to be aware that humor possesses destructive elements and may be used to intentionally or unintentionally hurt a person. Use of the “AT&T” principle⁵⁸ helps determine the appropriateness of the use of humor. Klein describes this principle as Appropriate, Timely, and Tasteful, which means that the therapist must be attuned to the patient’s humor style, culture, and current status (physical, emotional, and cognitive) before introducing humor and facilitating laughter.³⁵

Leisure exploration is defined in the “Occupational Therapy Practice Framework: Domain and Process (2nd edition)”⁴⁶ as “identifying interests, skills, opportunities, and appropriate leisure activities,” and leisure participation is “planning and participating in appropriate leisure activities; maintaining a balance of leisure activities with other areas of occupation; and obtaining, using, and maintaining equipment and supplies as appropriate” (p. 632). While exploring leisure with the client, the occupational therapist will be concerned with the appropriateness of such occupations with respect to age, gender, cultural fit, and meaning for the specific individual—concerns addressed in the next section.

Meaningful Leisure Occupations: Age, Cultural Issues, and Gender

Clients choose the leisure occupations that they want to pursue.^{46,62} Choices may be based on past experiences or on a desire to explore something new. As people move through the developmental stages of adulthood, the occupation of leisure may vary in intensity and time allotted. The continuity theory of aging suggests that personality plays a major role in adjustment to aging. Because personality does not radically change throughout life, one’s preferences, lifestyle, and activities remain relatively the same in individuals exhibiting successful aging.^{5,13,44,65}

Age and Leisure

Knowledge of the typical progression through adulthood, common life stage choices of leisure activities, and the ways that physical disabilities may disrupt participation in leisure activities is critical for occupational therapists. Armed with this information, therapists are able to discover gaps in developmental stages and to assist clients in the mastery of valued and meaningful occupations.²⁰

Young Adulthood (20 to 40 Years)

Young adults are typically healthy, active, working, and engaged in relationships. Erikson’s sixth stage of psychosocial development, intimacy versus isolation, describes young adulthood as a time in life when people know who they are and are ready to form intimate relationships with others.⁴⁹ Inability to make commitments on an intimate level may lead to isolation. Levinson views this age period as a time of becoming independent from parents, choosing and beginning an occupation, and imagining one’s dream future.⁴⁹ Young adults typically settle down and choose interests that encompass family, work, and leisure activities.

Examples of leisure activities in which young adults engage may include social and family group activities, sports (e.g., basketball, off-road biking), exercise, travel, computer games, surfing and social networking on the Internet, hobbies and crafts (e.g., scrapbooking), outdoor activities, dancing, dating, and sex.

Accidents or physical disorders affecting an individual’s areas of occupation, performance skills, and body functions can severely impede progress through the normal activities of young adulthood and may delay the development of age-related roles such as spouse, parent, employer/employee, social participant, participator in leisure occupations, and sexual being. Persons who are at the beginning stage of adulthood and who sustain an irreversible injury may need to redefine themselves to successfully navigate the aging process. Leisure problems may include social isolation and changes in relationships, lack of ability to perform favorite sports, difficulty traveling, and decreased knowledge of how to creatively express the self.^{28,33,64} A sense of incompetence may ensue that could lead to depression.

Middle Adulthood (40 to 65 Years)

People in this age group are typically immersed in work and family life. They have usually developed expertise in their chosen field of employment and may have risen to supervisory levels. Financial independence is attained as people purchase homes and cars and build a nest egg. Some adults in this age group experience a midlife review of self and career and may change careers or retire. This is the stage of generativity versus stagnation (Erikson’s seventh stage of psychosocial development) in which the person enjoys developing the skills and talents of younger people (e.g., serving as a sports coach or work mentor).⁴⁹ Lack of generativity may lead to stagnation in life, disappointment, and burnout.²⁰

Examples of leisure activities typical of this age group are friend and family activities, sports (e.g., golf, bowling, coaching), card games, Internet surfing, socializing and shopping, travel, pet care, gardening, movies, attending plays and concerts, boating, fishing, reading, television, bike riding, dating, and sexual activity with a spouse or partner.

Disruption caused by a physical disability can impair the individual’s ability to engage in cherished leisure occupations. Spouses or significant others are called on to be caregivers, and the relationship may undergo changes. Leisure occupations such as travel and fishing may be put aside for the more immediate concerns of learning to cope with self-care, rehabilitation exercises, and therapeutic equipment.^{61,69} Friend relationships often change as well. For example, if two men had a friendship based on golfing every Saturday and one of them suffers a stroke and needs to use a wheelchair, either they will have to be proactive and figure out a way to enjoy each other’s company in a new way (such as playing golf with adapted equipment or trying out a new activity that they both enjoy), or they may drift apart. Finally, changes caused by life transitions such as menopause and empty nest syndrome are ameliorated many times by engagement in leisure occupations. For example, a qualitative study of women experiencing menopause indicated that leisure activities not only provide women with a sense of familiarity, security, and continuity but also provide them

with opportunities to develop new interests and to focus on themselves.⁵²

Late Adulthood (65 Years and Older)

Occupational roles typically go through transformations during this age span. Some changes seen in older adults include a shift of emphasis from parent to grandparent and worker to retiree or volunteer. As time spent in work/career diminishes, free time increases, and leisure occupations come into full bloom. The interests and activities that were put aside during career attainment can now be given full rein.²⁰ Erikson’s last stage of psychosocial development (stage 8, ego integrity versus despair) is described as the time when people review their lives and hopefully accept the life cycle as being complete and satisfying.⁴⁹ The “use it or lose it” principle is particularly important as people age. If activity levels are not maintained, strength, coordination, and skills may deteriorate rapidly.⁴⁹ Some aspects of aging that are considered fairly normal include diminishing hearing and eyesight, arthritis, and decreased sensory abilities, as well as general aches and pains.

Examples of leisure activities in which older adults engage are dining with or cooking for friends and family, social activities, card games, bingo, travel, sports (e.g., golf, game attendance or viewing on TV), walking, exercise at the gym, swimming, boating, sexual activity with a spouse or partner, reading, television, pet care, gardening, and hobbies (e.g., crafts, collecting, scrapbooking).

If a physically disabling event or disease progression occurs, spouses or significant others may be called on to assist their partners in performing daily living activities, including leisure. This can be problematic because the caregiver may also be advanced in age and may not be well suited to provide the care needed.⁴² Consequently, leisure activities may be forgotten except for sedentary activities such as television viewing.⁶⁹

For some, isolation and depression could set in and diminish the person’s quality of life. A quantitative study of 383 retirees indicated that leisure plays a significant role in achieving a high level of life satisfaction, which the authors purport is equivalent to successful adaptation to retirement.⁴⁴ In another study of 324 older Swedes living in the community, researchers discovered that people who increased participation in leisure activities reported being more satisfied with life. “The results suggest that maximizing activity participation is an adaptive strategy taken by older adults to compensate for social and physical deficits in later life”⁵⁸ (p. 528). Mental acuity may also be strengthened or preserved by engaging in novel activities. Engagement with life is vital to successful aging.⁵⁹

Culture and Leisure

Because of the increasing diversity of the U.S. populace, occupational therapists must have knowledge of how culture affects the choices and performance of leisure activities for clients. The U.S. Census Bureau (www.census.gov) reports

TABLE 16-1 Ethnic Groups in the United States, 2009 Population Estimates

Ethnic Group	Percentage of Population	Population Centers
White	65.1%	Midwest and Northeast
Hispanic or Latino	15.8%	Southwest and California
Black or African American	12.3%	Southeast and Mid-Atlantic
Asian American	4.4%	West and Northeast
American Indian and Alaskan Native	0.9%	Northwest, West, Southwest, and Midwest
Native Hawaiian and other Pacific Islanders	0.1%	Hawaii and West
Two or more races reported	1.4%	

Data from U.S. Bureau of the Census, 2009 population estimates. Available at: www.census.gov.

that although the white population is still the majority (65%), by the year 2050, whites and minority groups overall will be roughly equal in size. Ethnic groups are currently concentrated in various areas of the country (Table 16-1). Thus, depending on where occupational therapy is delivered, therapists should make themselves familiar with leisure activities related to the culture of their clients (Table 16-2).

Leisure Occupations Related to Culture

Games and leisure occupations instruct, inspire, and reflect the values and beliefs of the parent cultures. For persons immigrating to a new country (e.g., Hispanics to the United States), leisure activities can be used to maintain connections with their heritage. Other possible uses of leisure that aid community integration are to (1) gain pleasure from the new environment and people and (2) learn language and customs.³⁴ Watching television and reading are two ways that newcomers use leisure to improve conversational skills and to understand cultural features.⁴ Depending on the interest of the client involved, occupational therapists may offer leisure occupations that (1) reflect the client’s traditional background, thus fostering security in a new country, or (2) provide leisure experiences of the new country to increase learning, comfort, and integration (Table 16-2). Keeping the leisure interventions client centered is the critical element to a successful outcome. Table 16-3 presents ideas for leisure resources.

■ **TABLE 16-2** | Examples of Leisure Interests and Occupations by Ethnicity

Ethnic Group	Possible Leisure Interests and Occupations
Hispanic/Latino	Music, dancing, video games, sports (e.g., soccer, races, arena football), needlework, concerts, movies, TV, socializing, cooking, travel to Mexico and Central/South America (minimal domestic US travel)
Black/African American	Socializing, sports (e.g., bowling, baseball, basketball), cooking, games (e.g., cards, gambling, board), TV, computers/Internet, running, weightlifting, woodworking, remodeling, sewing, quilting, gardening, music, dancing
Asian American	Board games (e.g., GO), tile games (e.g., mahjong), traditional cooking and arts, Asian language classes, gardening, sewing, tai chi, yoga, walking, computers, Internet surfing/shopping, travel to Asian destinations ⁴
American Indian	Sports (e.g., running, lacrosse, longball), outdoor traditions (e.g., canoe, kayak, archery), recreational pastimes (e.g., cup and ball, dice or deer button game, snowsnake), powwow (dancing, arts)

Leisure-Time Physical Activity by Gender, Age, and Racial/Ethnic Groups

Physical inactivity has been associated with various health risk factors such as obesity; cardiovascular disease, including stroke; diabetes; some cancers; and premature mortality.⁴³ Occupational therapists can aid clients to live a healthy lifestyle by encouraging them to participate in some type of leisure-time occupation that involves physical exercise at least several times a week. Some examples of leisure occupations that provide physical exercise but could be more attractive alternatives to some people are dancing, swimming, boating, bowling, golfing, gardening, and yoga.

To discover trends in physical activity levels, researchers at the Centers for Disease Control and Prevention conducted a randomized telephone survey of 170,423 persons from 35 states and the District of Columbia and asked, “During the past month, other than your regular job, did you participate in any physical activities or exercise such as running, calisthenics, golf, gardening, or walking for exercise?” Analysis of the data revealed that women, older adults, and the majority of racial/ethnic groups participated the least in leisure-time physical activities.²⁹ Blacks, Hispanics, and American Indians or Alaskan Natives more often reported fair or poor health, obesity, diabetes, and lack of leisure-time physical activity than did whites, Asians, or Pacific Islanders. Women in all cultures surveyed engaged in the least amount of physical activity.^{21,48}

Some barriers to leisure-time physical activity have been identified. Although many people of different cultures and ages believe that movement (e.g., exercise, gardening, walking) yields positive benefits such as improved health and appearance, they do not engage in physical activities because of “self-consciousness and lack of discipline, interest, company, enjoyment and knowledge.”¹⁶ Other barriers to activity were identified, such as lack of transportation, prohibitive cost, and perceived lack of safety. Social issues such as gender roles for activity and poor support from the family were also identified by minority women. As a barrier to activity, these women additionally reported problems with (1) language, (2) isolation in the community, and (3) childcare because of lack of relatives in the area. While planning intervention, occupational therapists can collaborate with clients to address these problems, find community resources, and develop strategies to improve participation in leisure-time physical activities.

Leisure Occupations: Evaluation and Intervention

The Occupational Therapy Practice Framework focuses on a client-centered approach and mandates that the first step in the process be that occupational therapists develop an occupational profile collaboratively with clients and family/caregivers.⁴⁶ The profile includes the client’s occupational history, past and current interests, performance, and values. Knowledge of the problems and goals that the client and

OT Practice Notes Barriers to Leisure Participation

Incurring any type of disability or health condition may result in barriers to leisure engagement. The following are some examples^{11,22}:

- Perception of constraint
- Loss of interest, motivation
- Lack of facilities/support, lack of physical access
- Reduced ability/limited tolerance of activity
- Lack of time
- Attitude of others (caregivers may not value leisure)
- Attitudes of fellow participants (awkwardness displayed by able bodied)
- Challenging behaviors (e.g., in those with neurologic disability)
- Communication issues (e.g., in those with cognitive deficits)
- Increased expense (as a result of adaptations, career support, equipment)

family/caregivers consider important gives the therapist a basis for a meaningful intervention plan. Evaluation includes formal and informal assessments conducted initially and over the course of the therapy process to guide the therapist in providing an individualized intervention program that meets the client’s expressed needs and desires. Examples of possible assessments that address the leisure area of occupation and a description of each are presented in [Table 16-4](#).

OT Practice Notes Evaluation and Intervention for Leisure Activities

To ensure successful performance of leisure activity, the occupational therapy practitioner needs a comprehensive approach to evaluation. Important components include the following information:

- Demographic material
- Social information, including family context
- Educational history
- Occupational history
- Military involvement
- Community and church involvement
- Typical daily routine
- Interests and hobbies
- Meanings assigned to occupations, including leisure occupations
- Mealtime interests
- Abilities
- Sensorimotor components
- Cognitive components
- Psychosocial components

■ **TABLE 16-4 | Leisure Assessments and Descriptions Used by Occupational Therapists**

Assessments	Descriptions
Occupational Profile ⁴⁶	Interview with the client (and family/caregivers if appropriate) to gather information about demographics, language, health status, and social and medical history. Questions addressing why the client needs occupational therapy services, what his or her concerns are, the client's occupational history (e.g., values, meanings associated with life experiences), and what the client's priorities are
Canadian Occupational Performance Measure ³⁹	Interview conducted before and after interventions to describe problems, level of satisfaction in performing activities, and level of perceived performance abilities in areas of self-care, productivity, and leisure
Role Checklist ⁴⁵	Interview to discover past, present, and future occupational roles (including leisure roles) and their value to the client
Activity Card Sort ⁸	Picture cards of adults performing instrumental, social-cultural, and leisure activities. Client sorts them into piles depending on their interest level. Provides a "retained activity level" score indicating engagement levels of performance of past and current activities
Modified Interest Checklist (available from Model of Human Occupation Clearinghouse)	Checklist of 68 activity items that assesses the client's level of interest (casual, strong, or no interest). Includes many leisure-time activities
Leisure Attitude Measurement Scale ⁵⁵	Scale of 36 items addressing attitudes toward leisure in three areas: cognitive, affective, and behavioral. Rated on a 5-point scale from "never true" to "always true"
Leisure Motivation Scale ⁹	Scale of 48 items addressing motivation to participate in leisure in four areas: intellectual activities, social activities, mastery activities, and stimulus-avoidance activities. Rated on a 5-point scale from "never true" to "always true"
Quality of Life Scale ^{14,23,69}	Perceived quality of life on a scale of 16 items (e.g., material comforts, expressing yourself creatively, socializing, participating in active recreation). Rated on a Likert scale of "very satisfied" to "very dissatisfied"
Play and Laughter Assessment ³⁷	Informal interview to determine the client's attitude toward use of humor, sense of humor, types of humor that the client has enjoyed, etc.
Performance Skills	Assessment of the client's ability to perform leisure occupations, including motor skills, process skills, communication, and interaction skills. These may be assessed by formal tests and by observation and analysis of client's performance during activity engagement in the appropriate context (e.g., analyze the client's ability to hold and manipulate cards during a card game; analyze the client's ability to put bait on a fish hook, manage the rod and reel, and catch and remove fish from the hook while seated by a lake)
Ohio Functional Assessment Battery: Standardized Tests for Leisure and Living Skills ⁴⁷	Designed for use in cognitively impaired individuals. Structured interview/questionnaire assessing interests, resources, participation, motivation, and barriers to therapy. Has 3 test options: Functional Living Skills Assessment, Quick Functional Screening Test, and Recreation and Leisure Profile
Context	Assessment of cultural, physical, social, personal, spiritual, temporal, and virtual contexts that may influence participation in leisure occupations
Client Factors	Assessment of body systems that support participation in leisure occupations (e.g., mental, sensory, neuromusculoskeletal, cardiovascular, respiratory and speech functions, pain, skin)

Intervention: Where There's a Will, There's a Way

Using information gathered during the evaluation process, an intervention plan incorporating leisure occupations is developed that the client and family/caregivers view as important to improving quality of life. Clients (including family or caregivers as necessary) and therapists develop goals and plan interventions together, thus ensuring that the client is motivated to engage in therapy sessions to the best of his or her ability.⁴⁶ In occupational therapy, leisure occupations can be a means and an end. As a means of intervention, the client is provided with the therapeutic use of leisure that is motivating because it is chosen and fun. Leisure as an end is seen when the client voluntarily engages in leisure occupations after therapy intervention ceases.⁴⁶ When developing discharge plans that include leisure, the therapist should consider “attributes of novelty and challenge, meaningful use of time, and identity construction,” which are imperative to the continued growth, adaptation, and quality of life of clients.⁶⁴ Occupational therapists may offer a variety of leisure activities delivered to individuals or

groups, depending on the relevance to the client’s interests, abilities, and activity demands. In the case of Kris (see Case Study: Kris), individual activities need to be mastered before group activity can be considered.

Balloon volleyball is a fun and social activity. For example, in a long-term care facility, residents with appropriate cognitive and motor skills can be organized into two teams, seated and facing each other. A real or simulated volleyball net is erected between the two teams and a balloon is hit back and forth. Music adds to the enjoyable atmosphere. This game can meet several occupational therapy goals such as improving eye pursuit, upper extremity range of motion, socialization, and cognition (keeping track of the score). In addition, because joking and laughing often occur, physical, social, and psychological benefits may be gained (see Box 16-1). The therapist must ensure that clients are interested in participating and that each person is safe, with wheelchairs locked and, if necessary, seat belts attached. Cardiac patients may not be appropriate to include because of the upper extremity workout and increased respiration, heart rate, and blood pressure that could occur.

TABLE 16-5 | Examples of Adapted Leisure Occupations

Leisure Occupation	Possible Adaptations
Gardening	Raised flower or vegetable garden beds to be accessible from a chair or wheelchair. Nonskid surface under pots to prevent sliding during potting
Golf	Adapted golf clubs (e.g., constructed to be used from a seated or wheelchair position or to be used one-handed), lower-extremity prosthetics specially made for golf
Playing cards	Card shuffler, card holder (Figure 16-1), large-print or Braille cards

FIGURE 16-1 Use of an adapted card holder placed on the left side to encourage Ray to scan to that side while enjoying a game of cards with a friend.

Computer activities or Internet surfing	Large monitor screen, large print font, voice-activated controls or software (e.g., Dragonspeak)
---	--

■ **TABLE 16-5** | Examples of Adapted Leisure Occupations—cont'd

Leisure Occupation	Possible Adaptations
Cooking	Energy conservation techniques, sliding instead of lifting heavy pots, nonskid surface to prevent slippage, rocker knife, perching stool
Pets	Canine companions to manage daily tasks (e.g., open drawers and doors, acknowledge phone ringing, obtain objects), as well as provide love and licks. Therapy dogs to visit clients in hospitals, skilled nursing facilities, and homes to bring joy and opportunities for touch (Figure 16-2). Pets such as fish, cats, dogs, and others provide companionship and may promote motivation for engagement in caring activities

FIGURE 16-2 Certified therapy dog visiting an occupational therapy client.

Bike riding For persons with lower-extremity weakness or paralysis, handcycles may be purchased. These bikes are propelled and controlled by arm strength and coordination (Figure 16-3)

FIGURE 16-3 Monica, a vivacious woman with paraplegia, rides a handcycle racing bike.

Adapting the Activity for Success

Occupational therapists are uniquely qualified to adapt the activity, including the equipment, the environment, or the nature of the activity, to make leisure occupations accessible to clients. By participating in leisure occupations that are meaningful, clients are able to continue to make positive adaptations that lead to greater life satisfaction. Table 16-5 describes some leisure occupations and possible adaptations.

Level of Functioning

Occupational therapists view the client as a whole person with a myriad of dimensions (e.g., physical, cognitive, spiritual, psychological). Leisure occupations are self-enhancers that add joy and pleasure to life. For effective implementation, activities need to be analyzed according to the individual's level of functioning (e.g., performance skills, performance patterns, client factors, activity demands, and

Case Study | Kris

Kris, a 22-year-old man with a spinal cord injury (paraplegia), has an avid interest in playing wheelchair basketball.

To prepare him for this sport, the occupational therapist works with him individually to order the correct wheelchair, strengthen his upper extremities, and develop skill in dribbling, catching/throwing the ball, and making baskets from the

wheelchair. Referral is then made to a recreational therapist, who helps Kris incorporate these basic skills into an existing team of players. By developing his individual skills before entering the group activity, his potential to successfully participate in his leisure activity of choice is increased.

Case Studies | Tina, John, and Miguel

Tina

Level of Function: Maximum Assistance Needed

Tina, a 41-year-old mother of two, had a severe stroke that left her unable to smoothly coordinate movement. She enjoys listening to tapes of her son playing the guitar.

Leisure Occupation

Occupational therapy assessment revealed that when Tina was positioned correctly, her left hand could be guided to hit a large button switch. Stephanie, the occupational therapist, connected the button switch to a tape player, which held a tape of her son's recent musical accomplishments. Her family members were instructed in how to assist Tina so that they could all participate in a valued leisure activity together (Figure 16-4).

FIGURE 16-4 Tina, with her husband Scott, using a large button device to turn on a tape player to listen to her son playing the guitar.

John

Level of Function: Moderate Assistance Needed

John, a 50-year-old man, suffered a traumatic brain injury 3 years earlier. He demonstrates poor dynamic balance, short-term memory deficits, and weakness on his right side. He uses a three-wheeled walker for ambulation. John lives with his wife and is independent in the majority of activities of daily living. His passion is bowling.

Leisure Occupation

After assessing his interests and performance abilities, his occupational therapist DeShawn accompanied John, his wife, and his adult son to the bowling alley. DeShawn called ahead

to make sure that the bowling alley was accessible and had accommodations for persons with disabilities. The lanes were set up with gutter bumpers and a bowling ball ramp. With a gait belt and moderate assistance, John was able to place a lightweight ball on the ramp, set up his shot, release the ball, and knock down some of the pins. When he, his wife, and his adult son saw that bowling was possible again, they set up a family night once a week to resume a cherished fun activity.

Miguel

Level of Function: Independent

Miguel, a 25-year-old single man, was in a skiing accident 5 years earlier and incurred a spinal cord injury that resulted in paraplegia. He progressed through rehabilitation and is independent in activities of daily living and instrumental activities of daily living. He uses a power wheelchair, drives, and has a job as a police dispatcher. Miguel has come to occupational therapy to upgrade his wheelchair and discuss leisure occupations. He reports that his free time is boring and he wants to return to a sport.

Leisure Occupation

Wheelchair sports abound in variety. Miguel's occupational therapist Eric began by helping Miguel explore the many options for persons wishing to participate as a wheelchair athlete, including basketball, mountaineering, hunting, rugby (the fastest-growing wheelchair sport), weightlifting, racing (including handcycle racing), tennis, javelin throwing, and snow skiing. When Miguel indicated that he might be interested in resuming his previously loved leisure occupation of camping, Eric showed him how to locate helpful resources such as magazines, journals, Websites, catalogs, and other related publications. For example, Butler wrote an article reviewing sports wheelchairs that might provide information on the chairs' suitability for traversing camping trails.¹⁵

Miguel was further directed to *New Mobility*, a magazine written for and by people with physical disabilities, which had an excellent article on accessible campgrounds, as well as suggestions for making a trip successful. Eric recommended other magazines as well, such as *Adapted Physical Activity Quarterly* and *Sports'n Spokes*, so that Miguel could read about others' experiences and stories and broaden his ideas of equipment and gadgets for wheelchair users. Eric was thrilled to hear from Miguel a few months later that he had indeed gone camping and that it was a "super experience!"

Threaded Case Study | Jeri, Part 2

Reconsider the questions posed regarding Jeri, a 29-year-old newly married woman whose case study opened the chapter:

Question 1: Is Jeri Really Ready to Be Discharged from Occupational Therapy?

Probably not. Although the occupational therapist has done a thorough job of teaching Jeri how to be competent in activities of daily living, we now know that there is more to life for occupational therapists to consider than instructing clients in personal care techniques. Occupational therapy assessments of leisure attitudes, interests, skills, and abilities need to be undertaken and a further intervention plan developed that addresses quality-of-life issues.

Question 2: Why Is Jeri Dissatisfied with Her Current Lifestyle?

Jeri is leading a restricted life when compared with her life before the accident. She has lost many of the activities that brought joy to her life. She is unable to do scrapbooking because she still lacks the fine motor coordination in her dominant hand to manipulate scissors and small decorative paper pieces. She wants to drive again and misses working as an interior designer, shopping, meeting friends for lunch, and running errands. Her husband treats her as though she will break and is unsure that she is capable of boating and fishing again. Jeri is no longer engaging in leisure activities that reaffirm her age-related competencies.

Question 3: What Interventions Could the Occupational Therapist Provide to Improve Jeri's Quality of Life?

To improve Jeri's ability to resume her cherished hobby of scrapbooking, the occupational therapist could provide fine motor activities that incorporate scrapbooking materials.

Manipulation of materials can be improved by gluing small pieces of paper onto sturdy cards to make them easier to hold and using adapted scissors for cutting. A predriving assessment and perhaps driver training may help Jeri resume her outside activities, or the assessment may determine that driving is not advisable at this time. If Jeri is unable to drive, the occupational therapist may determine that an intervention aimed at accessing and using public transportation may be the first step in increasing community independence.

A collaborative session with Jeri's husband can be set up to talk through his concerns and to instruct him in the use of adaptive equipment, transfers, and other means of assisting her in resuming former life roles such as fishing. Jeri, her husband, and the occupational therapist could discuss Jeri's missed social roles and need for emotional expression. They may set mutual goals that encourage Jeri and her husband to invite friends and family over for a few hours for socializing. She may also be interested in joining a brain injury support group that the occupational therapy department runs to provide her with needed peer interaction; her husband may also wish to be included in a support group for families. Sexual and sensual expression may be brought up in this meeting, and the occupational therapist could offer suggestions regarding communication of perceived changes, use of touch, and positions to enhance intimacy. The occupational therapist may also indicate referrals, as necessary. All of these leisure-related accomplishments will help re-establish 29-year-old Jeri's perception of herself as a whole human being.

context). Examples of clients by level of function, along with leisure occupations that are meaningful to the individual, are described in the case studies examining Tina, John, and Miguel.

Summary

Occupational therapists assist clients in attaining life satisfaction through a variety of occupations that are meaningful to the individual. Engaging and re-engaging in leisure occupations, which may include social interactions, movement, playfulness, and pleasure, are important aspects of a balanced lifestyle. Realizing that lack of leisure activities may lead to isolation and depression and detrimentally affect an individual's recovery and joy of life, occupational therapists need to include leisure evaluation, intervention planning, and implementation for persons with physical disabilities. Consideration of the client's age, gender, culture, interests, and environment is

paramount when investigating or implementing leisure so that intervention is client centered. A skilled occupational therapist can facilitate participation in meaningful leisure occupations that may lead to improved psychological and physical well-being, social relationships, and quality of life.

Review Questions

1. What can the absence of a meaningful leisure occupation lead to for people with a physical disability?
2. List five psychosocial benefits and five physical benefits of leisure activities.
3. Why is the client's cultural background important?
4. When should humor and laughter be used with caution?
5. What four factors are essential for modeling to be an effective intervention?
6. Why is it important for the client to be involved in setting his or her own goals?

■ **Learning Objectives** *After studying this chapter, the student or practitioner will be able to do the following:*

1. Describe the range of assistive technology options currently available for persons with physical disabilities.
2. Explain the human interface assessment (HIA) model.
3. Identify common solutions for enabling control of daily living devices through technology.
4. Discuss options for augmentative and alternative communications
5. Analyze input and output options for assistive technologies and match them to the needs of consumers.

Threaded Case Study | Gianna, Part 1

Gianna, a 26-year-old, has completed her undergraduate degree and applied to law school in the hope of becoming a lawyer. Her path to the legal profession is obstructed by her C4 level complete spinal cord injury, which she sustained 12 years previously in an automobile accident that killed her parents. Gianna is bright, articulate, and exceptionally popular in her rural community. She recently received a new wheelchair with sip-and-puff controls, which allows her mobility in her home and community, and she would now like to attend law school. Ultimately, Gianna would like to specialize in disability rights to support the civil rights of others with profound disabilities. She believes that her insider perspective on the issues might make her arguments more compelling when disabled workers are seeking reasonable accommodations.

The admissions office at the nearby university, which includes a law program, suggests that Gianna may have a difficult time completing the required work. As a law student, Gianna will have to research legal precedence in case law and write briefs. She can get into the library, which meets many of the requirements of the Americans With Disabilities Act (ADA), but will need to be able to navigate the legal records, take notes of her findings, and write formal responses to legal challenges. The counselor believes that Gianna, who has no movement below her neck, may find that the challenge of the legal profession exceeds her capabilities.

Gianna does have full-time attendant care, and the attendant would be allowed to sit with Gianna in the classroom and act as a note taker for her. (The school also provides lecture notes to disabled students within 3 days of a class session, if requested.)

However, since Gianna's attendant must constantly monitor Gianna's physical needs, the ability of the attendant to focus on the lecture may be impaired. In addition, since the attendant does not have the interest or background to study law, the ability of the attendant to identify what is important in the lecture is limited. Finally, because of the required hours and hourly wage, Gianna generally changes attendants every 6 months or so. The new attendant would not have a complete background to help in interpreting the material that Gianna is studying. In her home life, Gianna would like to be able to adjust the lights in the room, the room temperature, and radio station (she prefers to study with music in the background) that is playing without interrupting her attendant. She knows that she will always be dependent on others for bathing, dressing, meal preparation, and many other aspects of her activities of daily living. However, she thinks that if she were able to make fewer demands on her attendants, they might be able to remain in her employ longer.

Gianna is seeking an assistive technology consultation to explore technological aids to assist her in reaching her life goals.

Critical Thinking Questions

1. Which of Gianna's areas of occupation might be improved through the application of assistive technology?
2. What types of assistive technologies might assist Gianna in pursuing her activities and occupations?
3. What control strategies might be appropriate for Gianna?
4. Would Gianna benefit from output enhancement technologies?

What Is Assistive Technology?

A discussion of assistive technology should begin with a description of the general limits of the topic. This is made difficult because the legal definitions of assistive technology are not uniform. Assistive technologies are sometimes included in the category of rehabilitation technology.¹² In other cases, rehabilitation technology is considered an aspect of assistive technologies.⁸ A third category of universal designed technologies does not seem to fit into either category.¹¹ For purposes of this discussion, the author will

present a set of definitions that are within the current definitions, but not necessarily congruent with any particular statute.

Rehabilitative/Assistive/Universal Technologies

The category into which an enabling technology falls depends largely on its application, not on the specific device. What is for some people a convenience may be an assistive technology for another.

Rehabilitation Technology

To rehabilitate is to restore to a previous level of function. To be consistent with general usage, therefore, the term *rehabilitation technology* should be used to describe technologies that are intended to restore an individual to a previous level of function following the onset of pathology. When an occupational therapist (OT) uses a technological device to establish, restore, or modify function in a client, he or she is using a rehabilitative technology. Physical agent modalities such as ultrasound, diathermy, paraffin, and functional electric stimulation are examples of rehabilitative technology. Broadly, whenever an OT uses a technology, be it diathermy or a traditional occupational therapy activity such as leather working, with the primary goal of restoring strength, mobility, or function, the technology is rehabilitative. When these technologies have done their job, the client will have improved intrinsic function, and the technology will be removed.

Assistive Technology

Central to occupational therapy is the belief that active engagement in meaningful activity supports the health and well-being of the individual. When an individual has functional limitations secondary to some pathology, he or she may not have the cognitive, motor, or psychologic skills necessary to engage in a meaningful activity and may require assistance to participate in the desired task.

Ethical Considerations

Rehabilitative technologies are generally intended to be used within a therapy setting by trained professionals and over a short period of time. Because the technologies are intended to be used by trained professionals, they can have fairly complex or cryptic controls. The expectation is that the professional has had significant training before applying the technology. The professional guiding the use of such technologies is expected to ensure correct application of the technology and to protect the safety of the individual using the device.

To assist is to help, aid, or support. There is no implication of restoration in the concept of assistance. Assistive technologies, therefore, are technologies that assist a person with a disability to perform tasks. More specifically, assistive technologies are technologies, whether designed for a person with a disability or designed for mass market and used by a person with a disability, that allow that person to perform tasks that an able-bodied person can do without technological assistance. It may be that an able-bodied person would prefer to use a technology to perform a task (using a television remote control, for example), but it does not rise to the level of assistive technology as long as it is possible to perform the task without the technology.

Assistive technologies replace or support an impaired function of the user without being expected to change the

native functioning of the individual. A wheelchair, for example, replaces the function of walking but is not expected to teach the user to walk. Similarly, forearm crutches support independent standing but do not, of themselves, improve strength or bony integrity and thus will not change the ability of the user to stand without them.

Because they are not expected to change the native ability of the user, assistive technologies have different design considerations. They are expected to be used over prolonged periods by individuals with limited training and possibly with limited cognitive skills. The technology, therefore, must be designed so that it will not inflict harm on the user through casual misuse. The controls of the device must be readily understood such that although some training may be required to use the device, constant retraining will not be. The device should not require deep understanding of its principles and functions to be useful.

One significant difference between rehabilitation technology and assistive technology occurs at the end of the rehabilitation process. At this point the client no longer uses rehabilitation technologies but may have just completed training in the use of assistive technologies. The assistive technologies go home with the client; the rehabilitation technologies generally remain in the clinic. Some technologies do not fit neatly into these categories since they may be used differently with different clients. Some clinicians use assisted communication as a tool to train unassisted speech for their clients. For other clients, assisted communication may be used to support or replace speech. In the first case, the technology is rehabilitative. In the second, the same technology may be assistive.

Universal Design

Universal design is a very new category of technology. The principles of universal design were published by the Center for Universal Design at North Carolina State University in 1997,¹¹ and their application is still very limited. The concept of universal design is very simple: if devices are designed with the needs of people with a wide range of abilities in mind, they will be more usable for all users, with and without disabilities.

This design philosophy could, in some cases, make assistive technology unnecessary. A can opener that has been designed for one-handed use by a busy housewife will also be usable by a cook who has suffered a cerebral vascular accident and now has the use of just one hand. Since both individuals are using the same product for the same purpose, it is just technology, not assistive technology. Electronic books on dedicated eReaders such as Kindle or iPad include features to allow them to be used as “talking books.” The goal here is to provide a “hands-free, eyes-free” interface so that the books can be used by commuters while driving. However, the same interface will meet the needs of an individual who is blind and cannot see the screen or who has limitations in mobility and cannot operate the manual controls. No adaptation is necessary because the special needs

of the person with a disability have already been designed into the product.

The Role of Assistive Technology in Occupational Participation

The Occupational Therapy Practice Framework⁷ defines the appropriate domain of occupational therapy as including analysis of the performance skills and patterns of the individual and the activity demands of the occupation that the individual is attempting to perform.

Human Interface Assessment

Anson's human interface assessment (HIA) model provides a detailed look at the skills and abilities of humans in the skill areas of motor, process, and communication/interaction, as well as the demands of an activity (Figure 17-1, *A*). The HIA model suggests that when the demands of a task do not exceed the skills and abilities of an individual, no assistive technology is required, even when a functional limitation exists (Figure 17-1, *B*). Conversely, when a task makes demands that exceed the native abilities of the individual, the individual will not be able to perform the task in the prescribed manner (Figure 17-1, *C*). In these cases an assistive technology device may be used to bridge the gap between demands and abilities (Figure 17-1, *D*).

Although an assistive technology must be able to assist in performing the desired task, it also presents an interface

to the individual that must match the needs of the client. A careful match between the abilities of the human in sensory perception, cognitive processing, and motor output and the input and output capabilities of assistive technologies is necessary for assistive technologies to provide effective interventions.

Types of Electronic Enabling Technologies

Even though modern technology can blur some of the distinctions presented in this section, it is useful to consider assistive technologies in categories by the application for which they are used. This chapter deals only with electronic assistive technologies, which in terms of their primary application may be considered to fall into three categories: electronic aids to daily living (EADLs), alternative and augmentative communications (AACs), and general computer applications.

Electronic Aids to Daily Living

Electronic aids to daily living (EADLs) are devices that can be used to control electrical devices in the client's environment. Before 1998,³¹ this category of device was generally known as an environmental control unit, although technically, this terminology should be reserved for furnace thermostats and similar controls. The more generic EADL applies to control of lighting and temperature, in addition to control of radios, televisions, telephones, and other

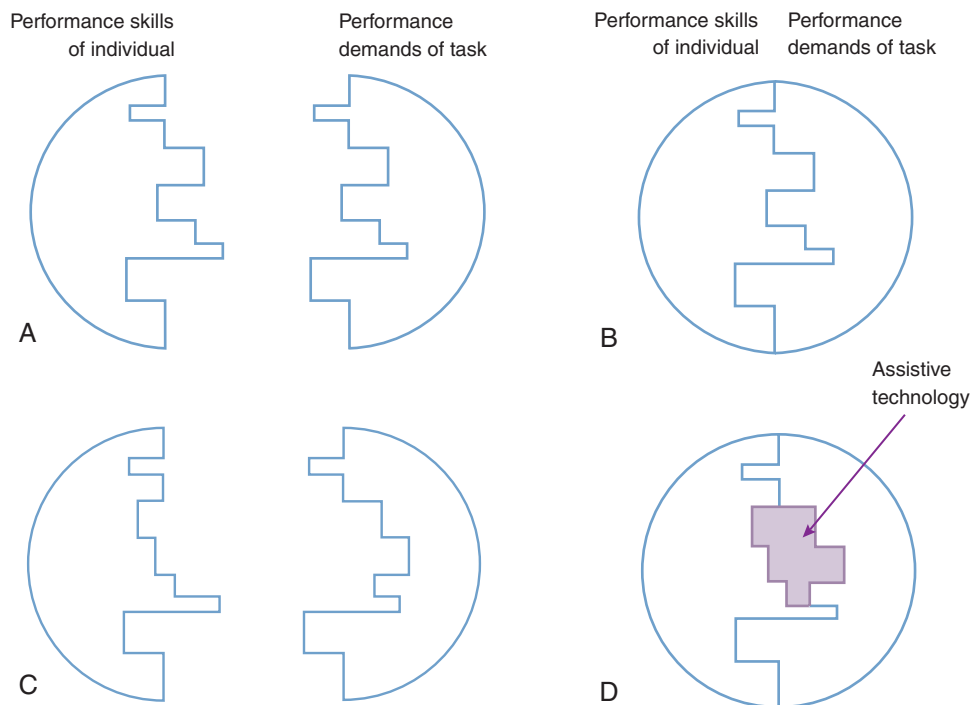

FIGURE 17-1 *A*, Skills of the individual and demands of the task. *B*, Match of the skills of the individual with the demands of the task. *C*, Mismatch of the skills of the individual and demands of the task. *D*, Assistive technology used to bridge the gap between the skills of the individual and the demands of the task.

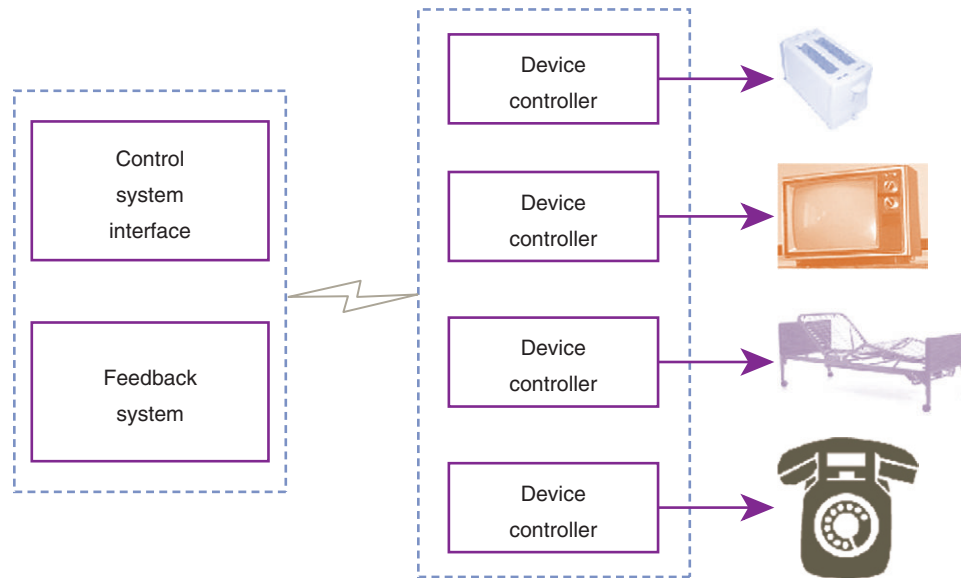

FIGURE 17-2 Components of an EADL system.

FIGURE 17-3 EADL control components.

electrical and electronic devices in the environment of the client (Figure 17-2).^{9,10,13}

As described by the HIA model, EADLs bridge the gap between the skills and abilities of the user and the demands of the device to be controlled. Within this context, EADL systems may be thought of in terms of the degree and types of control over the environment that they provide to the user. These levels of control are simple power switching, control of device features, and subsumed devices (Figure 17-3).

Power Switching

The simplest EADLs provide simple switching of the electrical supply for devices in a room. Though not typically considered EADLs, the switch adaptations for switch-adapted toys provided to severely disabled children would formally be included in this category of device. Primitive EADL systems consisted of little more than a set of electrical switches and outlets in a box that connected to devices

within a room via extension cords (e.g., Ablenet PowerLink 3). These devices are limited in their utility and safety since extension cords pose safety hazards to people in the environment through risks of both falls (tripping over the extension cords) and fires (overheated or worn cords). Because of the limitations posed by extension cords, EADL technology was driven to use remote switching technologies.

Second-generation EADL systems used various remote control technologies to remotely switch power to electrical devices in the environment. These strategies include the use of ultrasonic pulses (e.g., TASH Ultra 4), infrared light (e.g., infrared remote control), and electrical signals propagated through the electrical circuitry of the home (e.g., X-10). All these switching technologies remain in use, and some are used for much more elaborate control systems. Here, we are considering only power switching, however.

The most prevalent power-switching EADL control system is that produced by the X-10 Corporation. The X-10 system uses electrical signals sent over the wiring of a home

to control power modules that are plugged into wall sockets in series with the device to be controlled. (In a series connection, the power module is plugged into the wall, and the remotely controlled device is plugged into the power module.) X-10 supports up to 16 channels of control, with as many as 16 modules on each, for a total of up to 256 devices controlled by a single system. The signals used to control X-10 modules will not travel through the home's power transformer, so in single-family dwellings, there is no risk of interfering with devices in a neighbor's home.

This is not necessarily true, however, in an apartment setting, where it is possible for two X-10 users to inadvertently control each other's devices. The general set-up for early X-10 devices was to control up to 16 devices on an available channel so that such interference would not occur. In some apartments, the power within a single unit may be on different "phases" of the power supplied to the building. (These phases are required to provide 220-V power for some appliances.) If this is the case, the X-10 signals from a controller plugged into one phase will not cross to the second phase of the installation. A special "phase crossover" is available from X-10 to correct this problem. X-10 modules, in addition to switching power on and off, can be used via special lighting modules to dim and brighten room lighting. These modules work only with incandescent lighting but add a degree of control beyond simple switching. For permanent installations, the wall switches and receptacles of the home may be replaced with X-10-controlled units. Because X-10 modules do not prevent local control, these receptacles and switches will work like standard units, with the added advantage of remote control.

When they were introduced in the late 1970s, X-10 modules revolutionized the field of EADLs. Before X-10, remote switching was a difficult and expensive endeavor restricted largely to applications for people with disabilities and to industry. The X-10 system, however, was intended as a convenience for able-bodied people who did not want to walk across a room to turn on a light. Because the target audience was able to perform the task without remote switching, the technology had to be inexpensive enough that it was easier to pay the cost than to get out of a chair. X-10 made it possible for an able-bodied person to remotely control electrical devices for under \$100, whereas most disability-related devices cost several thousand dollars. Interestingly, the almost universal adoption of X-10 protocols by disability-related EADLs did not result in sudden price drops in the disability field, so many clinicians continue to adapt mass-market devices for individuals with disabilities.

Feature Control

As electronic systems became more pervasive in the home, simple switching of lights and coffee pots failed to meet the needs of individuals with a disability who wanted to control the immediate environment. With wall current control, a person with a disability might be able to turn radios and

televisions on and off but would have no control beyond that. A person with a disability might want to be able to surf cable channels as much as an able-bodied person with a television remote control. When advertisements are blaring from the speakers, a person with a disability might want to be able to turn down the sound or tune to another radio station. Nearly all home electronic devices are now delivered with a remote control, generally using infrared signals. Most of these remote controls are not usable by a person with a disability, however, because of dependence on fine motor control and good sensory discrimination.

EADL systems designed to provide access to the home environment of a person with a disability should provide more than on/off control of home electronics. They should also provide control of the features of home electronic devices. Because of this need, EADL systems frequently have hybrid capabilities. They will incorporate a means of directly switching power to remote devices, often using X-10 technology. This allows control of devices such as lights, fans, and coffee pots, as well as electrical door openers and other specialty devices.³⁷ They will also typically incorporate some form of infrared remote control, which will allow them to mimic the signals of standard remote control devices. This control will be provided either by programming in the standard sequences for all commercially available DVD players, televisions, and satellite decoders or by teaching systems, in which the EADL learns the codes beamed at it by the conventional remote. The advantage of this latter approach is that it can learn any codes, even those that have not yet been invented. The disadvantage is that the controls must be taught, which requires more set-up and configuration time for the user and caregivers. Because the infrared codes have been standardized, it is entirely possible for an EADL to include the codes for the vast majority of home electronics. As with "universal remote controls" for able-bodied users, the set-up process then requires only that the individual enter simple codes for each device to be controlled.

Infrared remote control, as adopted by most entertainment systems controllers, is limited to approximate line-of-sight control. Unless the controller is aimed in the general direction of the device to be controlled (most have wide dispersion patterns), the signals will not be received. This means that an EADL cannot directly control, via infrared, any device not located in the same room. However, infrared repeaters such as the X-10 Powermid can overcome this limitation by using radio signals to send the control signals received in one room to a transmitter in the room with the device to be controlled. With a collection of repeaters, a person would be able to control any infrared device in the home from anywhere else in the home.

One problem that is shared by EADL users and able-bodied consumers is the proliferation of remote control devices. Many homes are now plagued with a remote control for the television, the cable/satellite receiver, the DVD player/VHS recorder (either one or two devices), the home stereo/multimedia center, and other devices, all in the same

room. Universal remote controls can be switched from controlling one device to another but are often cumbersome to control. Some hope is on the horizon for improved control of home audiovisual devices with less difficulty. In November 1999, a consortium of eight home electronics manufacturers released a set of guidelines for home electronics called HAVi. The HAVi specification would allow compliant home electronics to communicate so that any HAVi device can control the operation of all of the HAVi devices sharing the standard. A single remote control could control all of the audiovisual devices in the home through a single interface. (As of summer 2010, the HAVi site lists six products, from two manufacturers, that actually use the HAVi standard, none of which appear to be in production, however.)

The Infrared Data Association (IrDA) is performing similar specifications work focusing purely on infrared controls. The IrDA standard will allow an infrared remote control to control features of computers, home audiovisual equipment, and appliances with a single standard protocol. In addition to allowing a single remote control to control a wide range of devices, IrDA standards will allow other IrDA devices, such as personal digital assistants (PDAs), personal computers, and augmentative communications systems, to control home electronics. Having a single standard for home electronics will allow much easier design of EADL systems for people with disabilities.

A more recent standard, V2,²³ offers a much greater level of control. If fully implemented, V2 will allow a single EADL device to control all of the features of all electronic devices in its vicinity, such as the volume of the radio, the setting of the thermostat in the hall, or the “push to walk” button on the crosswalk.

One interesting aspect of feature control by EADLs is the relationship between EADLs and computers. Some EADL systems, such as the Quartet Simplicity, include features to allow the user to control a personal computer through the EADL. In general, this is little more than a pass-through of the control system of the EADL to a computer access system. Other EADLs, such as the PROXi, were designed to accept control input from a personal computer. The goal in both cases is to use the same input method to control a personal computer as to control the EADL. In general, the control demands for an EADL system are much less stringent than those for a computer. An input method that is adequate for EADL control may be very tedious for general computer controls. On the other hand, a system that allows fluid control of a computer will not be strained by the need to also control an EADL. The “proper” source of control will probably have to be decided on a case-by-case basis, but the issue will appear again in dealing with augmentative communication systems.

Subsumed Devices

Finally, modern EADLs frequently incorporate some common devices that are more easily replicated than controlled remotely. Some devices, such as the telephone, are

so pervasive that an EADL system can assume that a telephone will be required. Incorporating telephone electronics into the EADL is actually less expensive, because of the standardization of telephone electronics, than inventing special systems to control a conventional telephone. Other systems designed for individuals with disabilities are so difficult to control remotely that the EADL must generate an entire control system. Hospital bed controls, for example, have no provisions for remote control, but they should be usable by a person with a disability.

Many EADL systems include a speakerphone, which will allow the user to originate and answer telephone calls by using the electronics of the EADL as the telephone. Because of the existing standards, these systems are generally analog, single-line telephones, electronically similar to those found in the typical home. Many business settings use multiline sets, which are not compatible with home telephones. Some businesses are converting to digital interchanges or “Voice Over IP” (VOIP), which are also not compatible with conventional telephones. As a result, the telephone built into a standard EADL may not meet the needs of a disabled client in an office setting. Before recommending an EADL as an access solution for a client’s office, therapists should check that the system is compatible with the telecommunications systems in place in that office.

Because the target consumer for an EADL will often have severe restrictions in mobility, the manufacturers of many of these systems believe that a significant portion of the customer’s day will be spent in bed and thus include some sort of control system for standard hospital beds. These systems commonly allow the user to adjust head and foot height independently, thereby extending the time that the individual can be independent of assistance for positioning. As with telephone systems, different brands of hospital beds use different styles of control. It is essential that the clinician match the controls provided by the EADL with the input required by the bed to be controlled.

Controlling EADLs

EADL systems are designed to allow individuals with limited physical capability to control devices in the immediate environment. Consequently, the method used to control the EADL must be within the capability of the client. Since these controls share many features in common with other forms of electronic enablers, the control strategies will be discussed below.

Augmentative and Alternative Communications

The phrase *augmentative and alternative communications* is used to describe systems that supplement (augment) or replace (alternative) communication by voice or gestures between people.³⁰ Formally, AACs incorporate all assisted communication, including tools such as pencils and typewriters as used to communicate either over time (as in leaving a message for someone who will arrive at a location after you leave) or over distance (sending a letter to Aunt

May). However, as used in assistive technology, AAC is considered the use of technology to allow communication in ways that an able-bodied individual would be able to accomplish without assistance. Thus, using a pencil to write a letter to Aunt May would not be an example of an AAC for a person who is unable to speak since an able-bodied correspondent would be using the same technology (pencil and paper) for the same purpose (social communication). However, when a person who is nonvocal uses the same pencil to explain to the doctor that she has sharp pains in her right leg, it becomes an AAC device since an able-bodied person would communicate this by voice.

There are two very different reasons why an individual might have a communication disorder. These can be grouped as language disorders and speech disorders. Following a brain injury that affects Wernicke's area, an individual may exhibit a language disorder. An individual with a language disorder has difficulty understanding and/or formulating messages (receptive or expressive aphasia), regardless of the means of production. Although there are degrees of aphasia from mild to severe/profound, a person with a language disorder, in most cases, will not benefit from AAC. In contrast, with a brain injury (from birth, trauma, or disease) that affects the speech motor cortex (Broca's area), an individual may be perfectly able to understand and formulate messages but not be able to speak intelligibly because of difficulty controlling the oral musculature. Such a person has no difficulty with language composition, only with language transmission. (In cases of apraxia, the motor control of writing can be as impaired as that of speaking, without affecting language.) In other cases, the physical structures used for speech generation (the jaw, tongue, larynx, etc.) may be damaged by disease or trauma. Although the person has intact neural control, the muscles to be controlled may not function properly. This person may well benefit from an AAC device.

AAC devices range from extremely low technology to extremely high technology. In hospital intensive care units, low-tech communication boards can allow a person maintained on a respirator to communicate basic needs (Figure 17-4). A low-tech communication board can allow a client to deliver basic messages or spell out more involved messages in a fashion that can be learned quickly. For a person with only a yes/no response, the communication partner can indicate the rows of the aid one at a time and ask whether the desired letter or word is in the row. When the correct row is selected, the partner can move across a row until the communicator indicates the correct letter. This type of communication is inexpensive, quick to teach, but very slow to use. In settings in which there are limited communication needs, it is adequate but will not serve for long-term or fluent communication needs.

To meet the communication needs of a person who will be nonvocal over a longer period, electronic AAC devices are frequently recommended by clinicians (Figure 17-5).

A	B	C	D	E	F	I hurt

OT Practice Note

In selecting a communication device, the clinician must consider the type of communication that the individual will use, as well as the settings in which the communication will take place.

Light²⁹ described four types of communication that we participate in: (1) expression of needs and wants, (2) transfer of information, (3) social closeness, and (4) social etiquette. In the intensive care setting noted earlier, most communication will occur at the first two levels. The communicator will want to express the basic needs of hunger, thirst, and relief of pain. He or she will wish to communicate with the doctor providing care, convey information

about where it hurts, and determine whether treatment seems to be working. In work or school settings, communication is often intended to convey information.

When participating in a classroom discussion, a student may want to be able to describe the troop movements in the Battle of Gettysburg, for example. In math class, the student may need to present a proof involving oblique angles and parallel lines. Such exchange of information may be spontaneous, as when called on in class, or may be planned, as in a formal presentation.

In a social or interpersonal setting, communication has a markedly different flavor. Teenagers may spend hours on the telephone with very little “information” exchanged but communicate shared feelings and concerns. At a faculty tea, much of the communication is very formulaic, such as “How are you today?” Such queries are not intended as questions regarding medical status, but simply recognition of your presence and an indication of wishing you well. (Historically, this query was originally expressed as “I hope I see you well today.” This phrasing more accurately expresses the sentiment but is somewhat longer.) The planning and fluency of communication in each domain are substantially different, and the demands on AAC systems in each type of communication are likewise very different.

An AAC system used solely for expression of needs and wants can be fairly basic. The vocabulary used in this type of communication is limited, and because the expressions tend to be fairly short, the communication rate is not of paramount importance. In some cases the entire communication system may be an alerting buzzer to summon a caregiver because the individual is in need. Low-tech communication systems such as that just described can meet basic communication needs for individuals whose physical skills are limited to eye blinks or directed eye movement.

Low-tech devices may enable expression of more complex ideas. For example, a therapist became aware that his client with aphasia wished to communicate something. Since no AAC was available to this client, the therapist began attempting to guess what he wanted to communicate. After exhausting basic needs (“Do you need a drink? Do you need to use the bathroom?”), the therapist was floundering. Over the next 20 minutes, the client, in response to a conversation between a therapist and client at another treatment table, was able to communicate that his ears were the same shape as Cary Grant’s! Even a basic communication aid, such as the intensive care unit aid described earlier, would have allowed much faster transfer of this information.

Most development in AAC seems to be focused on the level of communicating basic needs and transfer of information. Information transfer presents some of the most difficult technological problems because the content of information to be communicated cannot be predicted. The designer of an AAC device would probably not be able to anticipate the need to discuss the shape of Cary Grant’s ears during the selection of vocabulary. To meet such needs, AAC devices must have the ability to generate any concept

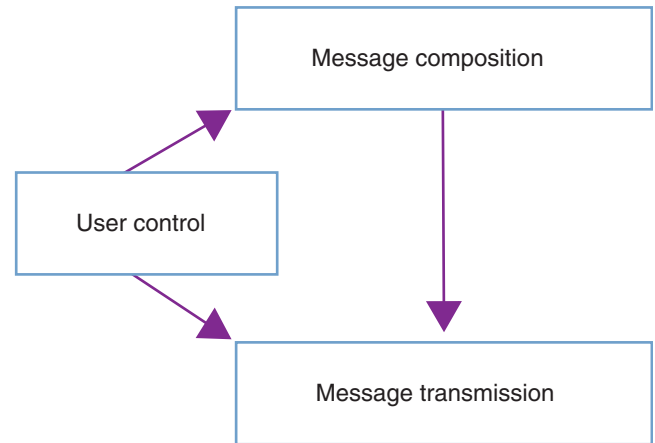

FIGURE 17-6 Components of an AAC device.

possible in the language being used. Making these concepts available for fluent communication is the ongoing challenge of AAC development.

Social communication and social etiquette present significant challenges for users of AAC devices. Although the information content of these messages tends to be low, since the communication is based on convention, the dialog should be both varied and spontaneous. AAC systems, such as the Dynavox, have provisions for preprogrammed messages that can be retrieved for social conversation, but providing both fluency and variability in social discourse through AAC remains a challenge. Current devices allow somewhat effective communication of wants. They are not nearly as effective in discussing dreams.

Parts of AAC Systems

In general, electronic AAC systems have three components (Figure 17-6): a user control system, which allows the user to generate messages and control the device; a message composition system, which allows the user to construct messages to be communicated to others; and a message transmission system, which allows the communication partner to receive the message from the user. The issues of user control of AAC devices are essentially the same as those for other electronic assistive technologies and will be discussed with access systems in general.

Message Composition

Most of the time, able-bodied people, as well as individuals with disabilities, plan their messages before speaking. (Many of us can remember the “taste of foot” when we have neglected this process.) An AAC device should allow the user to construct, preview, and edit communication utterances before they become apparent to the communication partner. This gives the user of an AAC device the ability to think before speaking. It also allows compensation for the difference in rate between message composition via AAC and communication between able-bodied individuals.

Able-bodied individuals typically speak between 150 and 175 words per minute.³⁵ Augmentative communication rates are more typically on the order of 10 to 15 words per minute, thus resulting in a severe disparity between the rate of communication construction and the expected rate of reception. Although input techniques (discussed later) offer some improvement in message construction rates, the rate of message assembly achieved with AAC is such that many listeners will lose interest before an utterance can be delivered. If words are spaced too far apart, an able-bodied listener may not even be able to assemble them into a coherent message!

The message construction area of an AAC device allows the individual to assemble a complete thought and then transmit it as a unit. A typical AAC device will include a display in which messages can be viewed before transmission. This area allows the communicator to review and edit the message that is being composed prior to transmitting it to the communication partner. This has two beneficial effects: the communicator can select words with care before communicating them, and it relieves the communication partner from the need for constant vigilance in conversation. The Atkinson-Shiffrin model of human memory suggests that human sensory memory will retain spoken information for only 4 or 5 seconds before it fades.¹ Communication between able-bodied people generally takes place quickly enough for a complete sentence to be held in sensory memory at once. When an able-bodied person is communicating with a person using an AAC device, the time between utterances may be too long to remain in memory. The able-bodied person loses focus and may not be able to maintain attention to the conversation. If messages come as units, the communication partner can respond to a query and then busy himself/herself in another activity while the communicator composes the next message. This is not unlike having a conversation via e-mail.

Message Transmission

When the communicator has finished composing a message, it can be transmitted to the communication partner. The means of transmission varies with the device and the setting. Some AAC devices use exclusively printed transmission. One of the first true AAC devices, the Canon Communicator, was a small box that included an alphanumeric keyboard. The box was strapped to the user's wrist, and the user tapped out messages that were printed on paper tape (message composition). When the message was completed, it was removed from the communicator and passed to the communication partner (message transmission).²⁰ On devices such as the Zygo LightWRITER, the message may be displayed on an electronic display that is made visible to the communication partner. Other systems use auditory communication in which the message is spoken out loud via speech synthesis. There is a tendency to think of voice output as more appropriate than text since able-bodied people generally communicate by voice.²⁰ In activities such

as classroom discussion, voice communication may be the most appropriate method of communication. In other settings, such as a busy sidewalk or a noisy shop, voice output may be drowned out or unintelligible, and printed output may result in more effective communication. In a setting where verbalization may disturb others, printed output may, again, be the transmission method of choice.

In settings in which voicing is the preferred method of communication, voice quality must be considered. Early AAC devices used voices that to novice listeners were only slightly more understandable than the communicator's unassisted voice. As speech synthesis technology has improved, AAC voices have generally become more intelligible. The high-quality voices of modern speech synthesizers have vastly improved intelligibility but continue to provide only a narrow range of variation and vocal expression. It is a mark of the improved state of speech synthesis that AAC users can now discuss who they would like to sound like rather than what they would like to sound like.

Communication Structure

Communications to be augmented may be categorized in terms of their intent, as well as in terms of their content, as proposed by Light.²⁹ At the top level, communication may be divided, with the conditions discussed earlier, into primarily verbal and primarily written. In these cases the categorization would be based on the mode of communication that would typically be used by an able-bodied person, not on the form that is being used by the augmented communicator.

Verbal Communications

One category of verbal communication is conversation. Conversation implies a two-way exchange of information. This includes face-to-face communication with a friend, oral presentation when question-and-answer sessions are included, small group discussions, and a conversation over a telephone. In all of these cases, rapid communication is required and the user is expected to compose and respond immediately. If the composition rate is too slow, communication will break down, and the conversation will cease. The augmented communicator may use "telegraphic" speech styles, but this results in a primitive style of language ("want food") that may be taken to indicate poor cognition.

Another form of verbal communication is an oral presentation in which no question-and-answer component is included or cases in which such a component is considered separately. In these cases the augmented communicator has ample preparation time to generate communications before delivery, and an entire presentation may be stored in a communication device before the time of delivery. In such cases, even though the time taken to prepare the message may be long, delivery of the message is not inhibited as long as the device has adequate storage for the entire presentation. Stephen Hawking, through the use of an ACC device, is

able to orally present formal papers at conferences just as well as his colleagues. His ability to respond to questions, however, is severely constrained. Nonetheless, because he is Stephen Hawking, colleagues will wait as long as necessary for his answers to questions. Less eminent augmentative communicators may find this more constraining.

Graphic Communications

The category of graphic communications includes all forms of communication that are mediated by graphic symbols. This includes writing using paper and pencil, typewriter, computer/word processor, calculator, or a drawing program. In this form of communication the expectation is that there is a difference between the time to create the message and the time to receive it. Within the realm of graphic communications there is a wide range of conditions and intents of communication that may influence the devices selected for the user.

Historically, graphic communication did not allow “conversation” in the traditional sense, other than the note passing that friends sometimes engage in when not attending to a presentation. Today, however, technologies such as “instant messaging” allow real-time conversations via written (typed) communication. The same need for fluency and immediacy of communication applies as for verbal conversations.

One specialized type of graphic communication is note taking. Note taking is a method of recording information as it is being transmitted from a speaker so that the listener can recall it later. The intended recipient of this form of communication is the person who is recording the notes. Because it is a violation of social convention to ask the speaker to speak more slowly to accommodate the note taker, a note-taking system must allow rapid recording of information. Note taking differs from merely recording a presentation in that it is a cognitively active process. Because spoken language is typically highly redundant, the note taker must attend to the speaker and listen for ideas that should be recalled later. Only key points need be recorded. However, since the listener is also the intended recipient, notes can be very cryptic and may be meaningless to anyone other than the note taker. The special case in which notes are taken for a student with a disability changes the process to one of recording a transcript rather than simply taking notes, which is a different type of communication.

Messaging is a form of graphic communication that shares many characteristics with note taking. Although the intended recipient is another person, shared abbreviations and nongrammatic language are common in messaging. The language that is common in adolescent e-mail is very cryptic and only barely recognizable as English (Figure 17-7), but it is a form of graphic messaging that communicates to its intended audience. In general, messaging does not demand the speed of input of note taking since encoding and receiving are not linked in time. However, instant messaging, which has become nearly ubiquitous, blurs the

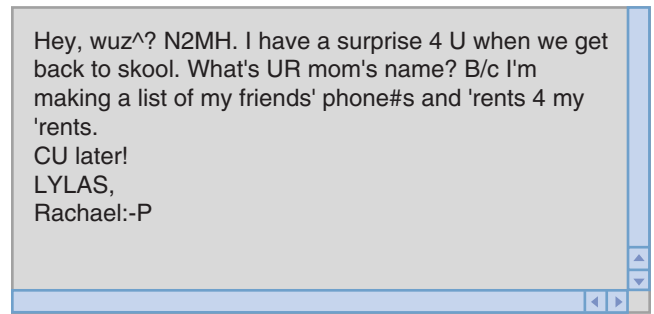

FIGURE 17-7 Example of message encryption in an adolescent e-mail.

lines between messaging and conversation. The expectation is generally of an immediate response, as in conversation. Social networking tools such as Twitter apply a different set of constraints. Because a Twitter feed may be “followed” by many people, obscure abbreviations cannot be used. However, because a single tweet can be no more than 140 characters long, messages must balance between being cryptic and informative.

The most language-intensive form of graphic communication is formal writing. This includes writing essays for school, writing for publication, and writing business letters or contracts. Formal writing differs from the previously discussed forms of graphic communication in that it must follow the rules of written grammar. It is expected that the communicator will spend significant time and effort in preparing a formal written document, and the abbreviations used in note taking and messaging are not allowed.

The most difficult form of formal communication may be mathematic notation. The early target of AAC devices was narrative text as used in messaging and written prose. Such language is commonly linear and can be composed in the same order that it is to be read. Mathematic expressions, on the other hand, may be two-dimensional and nonlinear. Simple arithmetic, such as $2 + 2 = 4$, is not excessively difficult. However, algebraic expressions such as

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

can be much more difficult for an AAC device to create. A relatively basic calculus equation such as

$$\sum_{n=1}^{+\infty} \frac{(-1)^{n+1} \cdot 1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots 2n} x^n$$

can be an impossible barrier to write, much less solve for the user of an AAC device. Although current technology allows prose construction with some facility, an AAC user will have marked difficulty with higher mathematics. Because similar issues are experienced on the World Wide Web, new communication protocols such as MathML¹⁷ are being developed that may, if incorporated into

augmentative communication devices, provide improved access to higher mathematics for AAC users.

General Computer Access

Computers have an interesting double role in the field of assistive technology. In some cases, using the computer is the intended activity. “Browsing” on the World Wide Web, for example, does not imply looking for specific information. It is a process of following links of immediate interest to see what is “out there.” The “Stumble-Upon” extension for the Firefox browser, for example, takes the browser to a random page that fits the interests declared by the user. Hobby computer programmers may use the computer simply to find what they can make it do. Using a computer can provide an individual with a disability a degree of control that is missing in much of the rest of life. In other cases, the computer is a means of accessing activities that would not be possible without it, so the computer can be considered in the same category as any other assistive technology. A student with a high-level spinal cord injury may need a computer to take notes in class. A business person with mild cognitive limitations may use computer technologies to organize and record information. A person with severe limitation in mobility may use social networks to remain in contact with friends and family. In these cases and many others, the computer is the path, not the destination.

As with the television remote control, the status of the computer (*vis-à-vis* assistive technology) depends on the status of the user, not on the type of computer. If a person with a disability is using a computer in the same way and for the same purposes as an able-bodied person would, it is not assistive technology. When a person with paraplegia accesses an online database of movies being shown at local theaters, this is not an assistive technology application because the same information is available without the computer. However, when a blind individual accesses the same database using the installed screen reader, it is an assistive technology since the printed schedule is not accessible. For a person with a print impairment, the computer can provide access to printed information either through electronic documents or through optical character recognition of printed documents, which can convert the printed page into an electronic document. Once a document is stored electronically, it can be presented as large text for a person with limited visual acuity or be read aloud for a person who is blind or profoundly learning disabled. Computers can allow the manipulation of “virtual objects” to teach mathematical concepts and constancy of form and develop spatial relationship skills that are commonly learned by manipulation of physical objects.²² Smart phones and PDAs may be useful for a busy executive but may be the only means available for a person with attention-deficit/hyperactivity disorder (ADHD) to get to meetings on time.³⁹ For the executive, they are conveniences, but for the person with ADHD, they can be assistive technologies.

Individuals using computers can locate, organize, and present information at levels of complexity that are not possible without electronic aids. Through the emerging area of cognitive prosthetics, computers can be used to augment attention and thinking skills in people with cognitive limitations. Computer-based biofeedback can monitor and enhance attention to task. Research in individuals with temporal processing deficits has led to the development of computer-modified speech programs that can be used to enhance language learning and temporal processing skills.^{33,38}

Beyond such rehabilitative applications, the performance-enhancing characteristics of the conventional computer can allow a person with physical or performance limitations to participate in activities that would be too demanding without the assistance of the computer. An able-bodied person would find having to retype a document to accommodate editing changes frustrating and annoying. A person with a disability may lack the physical stamina to complete the task without the cut-and-paste abilities of the computer. For the able-bodied person, the computer is a convenience. For the person with a disability, it is an assistive technology because the task is impossible without it. The applications of the computer for a person with a disability include all of the applications of the computer for an able-bodied person.

Control Technologies

All of these electronic enabling technologies depend on the ability of the individual to control them. Although the functions of the various devices differ, the control strategies for all of them share common characteristics. Since the majority of electronic devices were designed for use by able-bodied persons, the controls of assistive technologies may be categorized in the ways that they are adapted from the standard controls. Electronic control may be divided into three broad categories: (1) input adaptations, (2) performance enhancements, and (3) output adaptations.

Input to Assistive Technologies

Although there is a wide range of input strategies available to control electronic enablers, they can be more easily understood by considering them in subcategories. Different authors have created different taxonomies for the categorization of input strategies, and some techniques are classified differently in these taxonomies. The categorization presented here should not be considered as being uniquely correct, but merely as a convenience. Input strategies may be classified as those using physical keyboards, those using virtual keyboards, and those using scanning techniques.

Physical Keyboards

Physical keyboards generally supply an array of switches, with each switch having a unique function. On more complex keyboards, modifier keys may change the base function of a key, usually to a related function.² Physical

FIGURE 17-8 Physical keyboard with adaptive features.

keyboards are found in a wide range of electronic technologies, including typewriters/computers, calculators, telephones, and microwave ovens. In these applications, sequences of keys are used to generate meaningful units such as words, checkbook balances, telephone numbers, or the cooking time for a baked potato. Other keyboards may have immediate action when a key is pressed. For example, the television remote control has keys that switch power or raise volume when pressed. Other keys on the remote control may, like other keyboards, be used in combinations. Switching to channel 152 requires sequential activation of the “1,” “5,” and “2” keys.

Physical keyboards can be adapted to the needs of an individual with a disability in a number of ways (Figure 17-8). Most alphanumeric keyboards, for example, are arranged in the pattern of the conventional typewriter. This pattern was intentionally designed, for reasons related to mechanical limitations, to slow the user down. Most individuals with disabilities do not require artificial restraints to slow them down, so this pattern of keys is seldom optimal for assistive technologies. Alternative keyboard patterns include the Dvorak Two Handed, Dvorak One Handed, and Chubon (Figure 17-9).² These patterns offer improvement in the efficiency of typing that may allow a person with a disability to perform for functional periods of time.⁴

The standard keyboard is designed to respond immediately when a key is pressed and, in the case of computer keyboards, to repeat when held depressed. This behavior benefits individuals with rapid fine motor control but penalizes individuals with delayed motor response. Fortunately, on many devices the response of the keyboard can be modified. Delayed acceptance provides a pause between the instant that a key is pressed and the instant that the key press takes effect. Releasing the key during this pause will prevent the key from taking effect. This adaptation, if carefully calibrated, can allow a person to type with fewer mistakes, thereby resulting in higher accuracy and sometimes higher productivity. If not calibrated carefully, it will slow the typist without advantage.

FIGURE 17-9 Alternative keyboard patterns.

The scale of the standard keyboard provides a balance between the fine motor control and range of motion (ROM) of an able-bodied individual. The “optimum keyboard,” modeled after the IBM Selectric typewriters of the 1960s, was scaled to match the hands of women typists. However, a client with limitations in either ROM or motor control may find the conventional keyboard difficult to use. If the client has limitations in motor control, a keyboard with larger keys and/or additional space between the keys may allow independent control of the device. This adaptation may also assist people with a visual limitation. This applies to computer keyboards, but it also applies to such suboptimal keyboards as those of television remote controls, which are available in large scale from a number of vendors. However, to provide an equivalent number of options with larger keys increases the size of the keyboard, which may make it unusable for a person with limitations in ROM.

To accommodate limitations in ROM, the keyboard controls can be reduced in size. Smaller controls, placed closer together, will allow selection of the full range of options with less demand for joint movement. However, the smaller controls will be more difficult to target for people with limited motor control. A mini-keyboard is usable only by a person with good fine motor control and may be the only scale of keyboard usable by a person with limited ROM. However, as many users of “netbooks” have discovered, smaller keyboards are often not as usable for able-bodied typists.

To accommodate both limited ROM and limited fine motor control, a keyboard can be designed with fewer options. Many augmentative communication devices can be configured with 4, 8, 32, or 64 keys on a keyboard of a single size. Modifier or “paging” keys can allow access to the full range of options for the keyboard, but with an attendant reduction in efficiency. In this approach the person uses one or more keys of the keyboard to shift the meanings of all of the other keys on the keyboard. Unless this approach is

combined with a dynamic display, the user must remember the meanings of the keys.

Virtual Input Techniques

When an individual lacks the motor control to use an array of physical switches, a virtual keyboard may be used in its place. Virtual keyboards provide the functionality of a physical keyboard system by allowing the user to directly select from the array of options through a unique action, but it may not have physical switches for the actions to be performed. Instead, the meaning of the “selection” action may be encoded spatially, via pointing, or temporally by sequenced actions.

Pointing Systems

Pointing systems are analogous to using a physical keyboard with a physical pointer, such as a head or mouth stick.¹⁵ In these systems a graphic representation of a keyboard is presented to the user, and the user is able to make selections from it by pointing to a region of the graphic keyboard and performing a selection action. The selection action is typically either the operation of a single switch (e.g., clicking the mouse) or the act of holding the pointer steady for a certain period.

The pointer used for these systems may range from a beam of light projected by the user, the reflection of a light source from the user, or the position of a “solid-state gyroscope” worn by the user.⁶ Changing the orientation or position of the sensor moves an indicator over the graphic image of the keyboard to inform the user of the current meaning of the selection action.

Several augmentative communication systems now use a dynamic display in which the graphic keyboard can be changed as the user makes selections so that the meaning of each location of the keyboard changes as a message is composed. Dynamic displays free the user from having to either remember the current meaning of a key or decode a key with multiple images on it.

Pointing systems behave very much like physical keyboard systems, and many of the considerations of physical keyboards apply. The key size must balance the demands for fine motor control with the ROM available to the client. The keyboard pattern should be selected to enhance, not hinder function. The selection technique should facilitate intentional selections while minimizing accidental actions.

The ultimate pointing system to date is eye-tracking input. Eye-tracking systems are generally based on reflected infrared light from the surface of the eye. In general, these systems require extreme stability of the physical location of the eye and the camera observing the reflections.²⁸ Traditionally, this has meant that the user must hold his/her head extremely still for the system to be usable. Because of cost considerations, this method of input has not been a reasonable option for a person who can produce head movements, so the requirement for head stabilization has not been a

major issue. However, as eye gaze moves into mainstream technologies, there may be changes in these requirements.

The first mainstream products that incorporated eye tracking were hand-held camcorders, which had eye tracking built into the viewfinder. By tracking the portion of the screen being focused on, this eye tracking allowed the camera to focus on the part of the display that was of special interest to the person taking the video.

The demonstrated utility of these products has led to two divergent approaches to eye tracking in mainstream products. In the first approach, personal computer developers are exploring eye tracking as a means of detecting the action that the user would like to perform.³⁴ This tracking will allow the computer to anticipate the needs of the user. To work as a mainstream product, the system must be able to track the user’s gaze anywhere in front of the computer monitor. Challenges encountered in developing adequate technology to allow free movement while tracking eye gaze are delaying the introduction of such products. Efforts to achieve mainstream gaze tracking are built around the low-cost webcams included in many modern computers. At current camera resolutions, the task is quite difficult, but research is progressing. Increasing detail by zooming in on the eye allows commercial eye-tracking systems to work, but it requires that the eye remain in a very narrow field of view.

The second approach to using eye-tracking devices is similar to video cameras with built-in eye tracking; these systems work because the camera is held to the eye and moved with the eye. If an eye-tracking system were small enough to be mounted on the head, it would be much easier to use because the system would remain in a fixed relationship to the eyes. Currently, systems that combine head-mounted displays with eye tracking are being made available for the development of future products. A number of possibilities are opened by this combination. For example, a head-mounted display might project a control system that the user looks at to control devices and looks through for other activities. With binocular eye tracking combined with head tracking, an EADL system might be constructed that would allow the user to control devices simply by looking at them. There is currently no affordable, easy-to-use, and effective eye gaze input system. There are systems that are effective, easy to use, or affordable, but not all three. Although eye gaze is available for those who have no other option, it is currently competitive as an input method for those who do have other options to control their computer. However, now that mainstream engineers have discovered this technology, it will probably become less costly and more effective.

Switch-Encoding Input

An individual who lacks the ROM or fine motor control necessary to use a physical or graphic keyboard may be able to use a switch-encoding input method. In switch encoding, a small set of switches (from one to nine) is used to directly

How to type the letter *M* with 2 tongue strokes using the UCS 1000 and the Apple® Macintosh computer with *Miracle Typer™* software

access the functionality of the device. The meaning of the switch may depend on the length of time that it is held closed, as in Morse code, or on the immediate history of the switch set, as in the Tongue Touch Keypad (TTK).

In Morse code, a very small set of switches is used to type. In single-switch Morse, a short switch closure produces an element called a “dit,” which is typically written as “*.” A long switch closure produces the “dah” element, which is written as “-.” Formally, a “long switch closure” is three times longer than a short switch closure, which can be adjusted to the needs of the individual. Patterns of switch closures produce the letters of the alphabet, numbers, and punctuation. Pauses longer than five times the short switch closure indicate the end of a character. Two-switch Morse is similar, except that two switches are used: one to produce the “dit” element and a second to produce the “dah.” Because the meaning of the switches is unambiguous, it is possible for the dit and dah to be the same length, thereby potentially doubling typing speed. Three-switch Morse breaks the time dependence of Morse by using a third switch to indicate that the generated set of dits and dahs constitutes a single letter.

Morse code is a highly efficient method of typing for a person with severe limitations in motor control and has the advantage over other virtual keyboard techniques of eventually becoming completely automatic.^{5,32} Many Morse code users indicate that they do not “know” Morse code. They think in words, and the words appear on the screen, just as takes place in touch typing. Many Morse code users type at speeds approaching 25 words per minute, thus making this a means of functional writing. The historical weakness of Morse code is that each company creating a Morse interface for assistive technology has used slightly different definitions of many of the characters. To address this issue and to promote the application of Morse code, the Morse 2000

FIGURE 17-11 T9 keyboard.

organization has created a standard for Morse code development.³⁶

Another variety of switch encoding involves switches monitoring their immediate history for selection. The TTK, from newAbilities Systems, uses a set of nine switches on a keypad built into a mouthpiece that resembles a dental orthotic.

Early versions of the product used an “on-screen keyboard” called MiracleTyper (Figure 17-10). When using this input method, the first switch selection selects a group of nine possible characters, and the second switch action selects a specific character. This approach to typing is somewhat more physically efficient than Morse code but does require the user to observe the screen to know the current switch meaning. Later versions of the TTK used the keypad only as a mouse emulator to allow the user to select any on-screen keyboard desired for text entry.

A different approach to switch encoding is provided by the T9 keyboard (Figure 17-11), which is included in most cell phones with standard keypads. In this novel interface, each key of the keyboard has several letters on it, but the

user types as though only the desired character were present. The keyboard software determines from the user's input what word might have been intended. The disambiguation process used in the T9 keyboard allows a high degree of accuracy in determining which character the user intended, as well as rapid learning of the keyboard. This input technology is potentially compatible with pointing systems, described earlier, and can provide an excellent balance of target size and available options.

Speech Input

For many, speech input has a magical allure. What could be more natural than to speak to an EADL or computer and have one's wishes carried out. When first introduced by Dragon Systems in 1990, large-vocabulary speech input systems were enormously expensive and, for most, of limited utility. Although highly dedicated users were able to type via voice in 1990, almost no one with the option of the keyboard would choose to use voice for daily work. These early systems required the user to pause between each word so that the input system could recognize the units of speech. Today,²⁴ the technology has evolved to allow continuous speech, with recognition accuracy greater than 90%.²⁶ (The companies producing speech products claim accuracy greater than 95%.) Even though this advance in speech technology is remarkable, it does not mean that speech input is the control of choice for people with disabilities, for a number of reasons.

Speech recognition requires consistent speech. Although it is not necessary that the speech be absolutely clear, the user must say words the same way each time for an input system to recognize them. Consequently, the majority of people with speech impairments cannot use a speech input system effectively. Slurring and variability in pronunciation will result in a low recognition rate.

Speech input requires a high degree of vigilance during training and use. Before current speech technology can be used, it must be "trained" to understand the voice of the intended user. To do this, the system presents text to the potential user, which must be read into the microphone of the recognition system. In Windows 7, the speech system included uses responses to a tutorial to learn the individual user, disguise the training process, and provide the user with an overview of the system at the same time. If the user lacks the cognitive skills to respond appropriately to the cues presented, the training process will be very difficult. A few clinicians have reported success in training students with learning disabilities or other cognitive limitations to use speech input systems, but in general, the success rate is poor. Even after training, the user must watch carefully for misrecognized words and correct them at the time that the error is made. Modern speech recognition systems depend on context for their recognition. Each uncorrected error slightly changes the context, and eventually the system can no longer recognize the words being spoken. Spell checking a document will not find misrecognized words since each

word on the screen is a correctly spelled word. It just may not be the word that the user intended!

Speech input is intrusive. One person in a shared office space talking to a computer will reduce the productivity of every other person in the office. If everyone in the office were talking to their computers, the resulting noise levels would be chaotic. Speech input is effective for a person who works or lives alone, but it is not a good input method for most office or classroom settings.²⁵

The type of speech system used depends on the device being controlled. For EADL systems, discrete speech (short, specific phrases such as "light on") provides an acceptable level of control. The number of options is relatively small, and there is seldom a need for split-second control. Misrecognized words are unlikely to cause difficulty. Text generation for narrative description, however, places higher demands for input speed and transparency and may call for a continuous input method. Other computer applications may work better with discrete than with continuous input methods. Databases and spreadsheets typically have many small input areas, with limited information in each. These applications are much better suited to discrete speech than to continuous speech.

The optimum speech recognition program would be a system that would recognize any speaker with an accuracy of better than 99%. Developers of current speech systems say that based on advances in processor speed and speech technologies, this level of usability should be possible within about 5 years. However, they have been making the same prediction (within 5 years) for the past 20 years! Modern speech recognition systems are vastly better than those available 10 years ago and are also available at just over 1% of the cost of the early systems. However, even with these improvements, they are still not preferable to the conventional keyboard for most users.

Scanning Input Methods

For an individual with very limited cognition and/or motor control, a variation in row-column scanning is sometimes used.^{2,14,20} In scanning input, the system to be controlled sequentially offers choices to the user, and the user indicates affirmation when the correct choice is offered. Typically, such systems first offer groups of choices and, when a group is selected, offer the items in the group sequentially. Because the items were, in early systems, presented as a grid being offered a row at a time, such systems are commonly referred to as "row-column" scanning even when no rows or columns are present.

Scanning input allows the selection of specific choices with very limited physical effort. Generally, the majority of the user's time is spent waiting for the desired choice to be offered, so the energy expenditure is relatively small. Unfortunately, the overall time expenditure is generally relatively large. When the system has only a few choices to select among, as in most EADL systems, scanning is a viable input method. The time spent waiting while the system scans may

be a minor annoyance, but the difference between turning on a light now versus a few moments from now is relatively small. EADL systems are used intermittently throughout the day rather than continuously, so the delays over the course of the day are acceptable in most cases. For AAC or computer systems, however, the picture is very different. In either application, the process of composing thoughts may require making hundreds or thousands of selections in sequence. The cumulative effect of the pauses in row-column scanning will slow productivity to the point that functional communication is very difficult and may be impossible. Certainly, when productivity levels are mandated, the communication rate available via scanning input will not be adequate.

Integrated Controls

One area of current development is the long advocated idea of integrated controls.¹⁶ An individual with a profound disability is likely to require more than one type of control device. A person with severe motor involvement from cerebral palsy, for example, may require an augmentative communication system for interpersonal communication, an EADL for control of the local environment, a computer access system to complete job-related tasks, and a powered mobility device to navigate the community. Historically, each of these systems had their own control systems, with slightly different control strategies. The user of these multiple systems would have to move from control system to control system and have to learn how to control each of the systems.

With an integrated control system, the user would have a single interface that could control each assistive technology device. Since both AAC and computer access commonly involve language, the ability to use an AAC device to control a computer was an early goal. The 1994 standard for the general input device emulating interface (GIDEI)¹⁸ defined characters to be sent from an AAC device to a supporting computer to provide control equivalent to the keyboard and mouse. With GIDEI, an AAC user could use the same control interface to communicate with friends in the same room or to write a business proposal.

Since many devices can be used with a moving pointer, the joystick control of a powered wheelchair may offer another avenue to integrated controls. The same joystick could be used to move a selection icon on the display of an EADL or AAC device or the mouse pointer of a computer screen. Ideally, the communication between devices would be wireless, and the current Bluetooth standard for short-range, wireless communications offers to make such controls possible. (Bluetooth is a consortium of electronics companies whose goal is to develop a flexible low-cost wireless platform capable of short-distance communication.)

The question, for the clinician, will be whether the advantages of a single, generic control that is not optimal for any particular device would outweigh the costs of learning individual, optimal control strategies for each device.

Because the demands of controlling a powered wheelchair are significantly different from those for writing a formal proposal, changing channels on a television, or answering a question in a classroom, different control strategies might be necessary for each device. Whether a single control interface can support the optimal strategy for each device remains to be seen.

Rate Enhancement Options

For EADL systems, the rate of control input is relatively unimportant. As noted earlier, the number of control options is relatively limited, and selections are rarely severely time constrained. However, for AAC and computer control systems, the number of selections to be made in sequence is high, and the rate is frequently very important. Because a person with a disability cannot generally make selections at the same rate as an able-bodied person, rate enhancement technologies may increase the information transmitted by each selection. In general, language can be expressed in one of three ways: letter-by-letter spelling, prediction, and compaction/expansion. The latter two options allow enhancement of language generation rates.

Letter-by-Letter Spelling

Typical typing is an example of letter-by-letter representation and is relatively inefficient. In all languages and alphabets, there is a balance between the number of characters used to represent a language and the number of elements in a message. English, using the conventional alphabet, averages about six letters (selections) per word (including the spaces between words). When represented in Morse code, the same text will require roughly 18 selections per word. By comparison, the basic Chinese vocabulary can be produced by selecting a single ideogram per word; however, thousands of ideograms exist. In general, having a larger number of characters in an alphabet allows each character to convey more meaning but may make selection of each specific character more difficult.

Many AAC systems use an expanded set of characters in the form of pictograms or icons to represent entire words that may be selected by the user. Such semantic compaction allows a large vocabulary to be stored within a device but requires a system of selection that may add complexity to the device.¹³ For example, a device may require the user to select a word group (e.g., food) before selecting a specific word (e.g., hamburger) from the group. Using subcategories, it is theoretically possible to represent a vocabulary of more than 2 million words on a 128-key keypad with just three selections.

Prediction

Because messages in a language tend to follow similar patterns, it is possible to produce significant savings of effort with prediction technology. Two types of prediction are used in language: (1) word completion and (2) word/phrase prediction.

In word completion, a communication system (AAC or computer based) will, after each keystroke, present a number of options to the user representing words that might be typed. When the appropriate word is presented by the prediction system, the user may select that word directly rather than continuing to type the entire word out. Overall, this strategy may reduce the number of selections required to complete a message.²¹ However, it may not improve typing speed.²⁷ Anson³ demonstrated that when typing from copy using the keyboard, typing speed was reduced in direct proportion to the frequency of using word prediction. The burden of constantly scanning the prediction list overwhelms the potential speed savings of word completion systems under these conditions. However, when typing using an on-screen keyboard or scanning system, where the user must scan the input array in any case, word completion does appear to increase typing speed, as well as reduce the number of selections made.

Because most language is similar in structure, it is also possible, in some cases, to predict the word that will be used following a specific word. For example, after a person's first name is typed, the surname will frequently be typed next. When this prediction is possible, the next word may be generated with a single selection. When combined with word completion, next-word prediction has the potential to decrease the effort of typing substantially. However, in many cases this potential is unrealized. Many users, though provided with next-word prediction, become so involved in spelling words that they ignore the predictions even when they are accurate. The cognitive effort of switching between "typing mode" and "list scanning" mode may be greater than the cognitive benefit of not having to spell the word out.¹⁹

Compression/Expansion

Compression/expansion strategies allow limited sets of commonly used words to be stored in unambiguous abbreviations. When these abbreviations are selected, either letter by letter or through word completion, the abbreviation is dynamically replaced by the expanded form of the word or phrase.^{2,14}

Because the expansion can be many selections long, this technology offers an enormous potential for energy and time savings. However, the potential savings are available only when the user remembers to use the abbreviation rather than the expanded form of a word. Because of this limitation, abbreviations must be selected carefully. Many abbreviations are already in common use and can be stored conveniently. Most people will refer to the television by the abbreviation TV, which requires just 20% of the selections to represent it. With an expansion system, each use of TV can automatically be converted to "television" with no additional effort of the user. Similarly, TTFN might be used to store the social message "Ta-ta for now."

Effective abbreviations will be unique to the user rather than general. An example of an effective form of

abbreviations would be the language shortcuts commonly used in note taking. These abbreviations form a shorthand generally unique to the individual and allow complex thoughts to be represented on the page quickly in the course of a lecture. A clinician should work carefully with the client to develop abbreviations that will be useful and easily remembered.

Another form of "abbreviations" that is less demanding to create involves corrections of common spelling errors. For persons, either students or adult writers, who have cognitive deficits that influence spelling skills, expansions can be created to automatically correct misspelled words. In these cases the "abbreviation" is the way that the client generally misspells the word, and the "expansion" is the correct spelling of the word. Once a library of misspelled words is created, the individual is relieved of the need to worry about the correct spelling. There are those who maintain that this form of adaptation will prevent the individual from ever learning the correct spelling. In cases in which the client is still developing spelling skills, this is probably a valid concern, and the adaptation should not be used. However, for individuals with a cognitive deficit in which remediation is not possible, accommodation through compression/expansion technology is a desirable choice.

None of these technologies will allow a person with a disability to produce messages at the same rate as an able-bodied person. However, individually and collectively, they can make generation of the message significantly more efficient than it would be without them. The techniques are not mutually exclusive. Icons can be predicted by using "next-word" techniques. Abbreviations can be used in conjunction with word completion and word prediction technologies.

Output Options

Control of assistive technologies involves a cycle of both human output and human input matched to technology input and technology output. Individuals who have sensory limitations may have difficulty controlling assistive technologies (or common technologies) because they are unable to perceive the messages that are being sent to them by the technology. For these individuals, adaptations of the output of the technology may be required. These adaptations generally depend on one of three sensory modalities: (1) vision, (2) hearing, or (3) tactile sensation.

Visual Output

The default output of many types of electronic technology is visual. Computer screens are designed to resemble the printed page. AAC systems have input that looks like a keyboard and, generally, a graphic message composition area. EADLs use display panels and lighted icons to show the current status of controlled devices. Perception of all these controls depends on the user having visual acuity at nearly normal levels. When the client has some vision but it is limited, some adaptations may be required.

Colors and Contrast

Many types of visual impairment affect the ability to separate foreground and background colors. In addition, bright background colors can produce a visual glare that makes the foreground difficult to perceive. In accommodating visual deficits, the clinician should explore the colors that are easily perceived by the individual and those that are difficult. Background colors, for most people, should be muted, soft colors that do not produce a strong visual response. Icons and letters, in contrast, may be represented in colors that provide visual contrast with the background. Very bright or strident colors should be avoided in both cases, and the specific colors and contrast levels required by the user must be selected on an individual basis.

Image Size

Visual acuity and display size present difficulty in output display that closely mirrors the issues that ROM and fine motor skills present in keyboard design. A person with 20/20 vision can generally easily read text that is presented in letters about $\frac{1}{8}$ of an inch high. (This is equivalent to a page printed in a 12-point font.) On a typical display this allows the presentation of between 100 and 150 words of text at a time or a similar number of icons for selection. If the user has lower visual acuity, the letter/icon size must be increased to accommodate the loss of acuity. Larger icons, however, require either fewer letters shown at a time or increased display size. For people with severe visual limitations, as with individuals with severe fine motor limitations, it would be impractical to display all choices at once.

Screen enlargement programs² typically overcome this limitation by showing a part of the full screen at a time and moving the portion that is expanded to the area most likely to be of interest to the user. The visual effect is similar to viewing the screen through a magnifying glass that the user moves over the display. Most programs can be configured to follow the text insertion point, the mouse pointer, or other changes on the display. Navigation is a serious problem with all such programs. When the user can see only a small portion of the screen at a time, the landmarks that are normally available to indicate the layout of the text on a page may be invisible because they are not in the field of view. Any screen enlargement program must provide a means of orienting to the location on the screen that is usable by the client.

AAC systems can accommodate the needs of a user with low visual acuity by using precisely the same techniques that are used for a person with limited fine motor control. The keyboard of the device can be configured with fewer, larger keys, each of which has a larger symbol to represent its meaning. However, as with keyboards for those with physical limitations, the result is either fewer communication options or a more complex interface for the user. In addition, these accommodations do not adapt the size of the message composition display, which may be inaccessible to a user with visual limitations.

Speech Output

It is very important to keep the difference between voice input and voice output clearly in mind. In voice input, the user speaks and the spoken word is converted into commands within the assistive technology. In voice output, the device communicates with the user through auditory means and converts printed words or commands into voice. Voice output technology has been in existence for much longer than voice input and is a more mature technology—not perfect, but more mature.

The demands of voice output are very different depending on the application and the intended listener. In general, it can be divided into systems in which a second person is the listener or the user is the listener.

Second Person As Listener

When used in AAC applications, voice output is almost always intended to be understood by a person who may have little experience with synthetic voices. For example, if an AAC user is at the corner market buying two pounds of hamburger for dinner, the butcher will have had very little experience with a synthetic voice. When asking for directions on the street corner, not only will the listener have little previous experience, but the AAC's voice will also be competing with the sounds of trucks and buses.

To be understandable by novice listeners in real-world environments, a synthetic voice should be clear and as human sounding as possible. The voice will be easily understood to the extent that it sounds like what the listener expects to hear. Ideally, the voice should provide appropriate inflection in the spoken material and be able to convey emotional content. Current AAC systems do not convey emotional content well, but high-end voice output systems do sound very much like a human speaker. Under adverse conditions, they will remain less understandable than a human speaker because the facial and lip movements that provide additional cues to the sounds being produced do not accompany synthetic voices.

User As Listener

When used for computer access or EADLs, voice quality need not be as human sounding. In either case, the user has the opportunity to learn to understand the voice during training. In EADL applications, there will be relatively few utterances that must be produced, and they can be designed to sound as different as possible so that there is little chance of confusion. General voice output for an entire language is somewhat more difficult, though, because many words sound similar and can easily be confused.

For general text reading, however, the primary issue is voicing speed. As noted earlier, humans generally talk between 150 and 175 words per minute. However, most humans also read between 300 and 400 words per minute. A person who depends on a human-sounding voice for reading printed material will be limited to reading at less than half the speed of able-bodied readers. To be an effective

text access method, synthetic voice output must be understandable at speeds in excess of 400 words per minute. This will obviously require significant training since untrained people without disabilities cannot understand speech at such speeds. However, with training, speech output is a very useful way for a person with a visual limitation to access printed material.

Speech is a useful tool in two cases: (1) when it replaces voice for a person with a disability and (2) when the user is not able to use vision to access the technology. AAC devices using voice provide the most “normal” face-to-face communication available. Able-bodied people, in most conditions, communicate by voice. People with disabilities generally want to communicate in similar fashion. The other application of voice is “eyes-free” control. In the mass market for able-bodied consumers, these applications include presenting information over the telephone, while driving, or in other settings in which a visual display might be difficult to use. All these situations are important for people with disabilities as well. In addition, assistive technologies using voice output may be intended for use by people with print impairments. The category of print impairments includes conditions that result in very low vision and/or blindness, as well as conditions that result in an inability to translate visual stimuli to language and those that make manipulation of printed material difficult.

The one weakness of voice output technologies lies in its use for people who are developing language skills. Because English is an irregular language, with many letter combinations making similar sounds, it is almost impossible to learn spelling by listening to the sound of words. Accordingly, children who are blind from birth may not be good candidates for speech output as the primary language access method because the structure of words is lost when converted to speech. For these children and for many others, tactile access is a better tool and is, in fact, mandated under the Individuals with Disabilities Education Act (IDEA).⁴⁰

Tactile Output

The oldest method for individuals with visual deficits to access printed material is Braille. In 1829, Louis Braille developed the idea of adapting a military system that allowed aiming artillery in darkness and writing secret messages to provide a method of reading for students at the National Institute for the Young Blind in Paris.⁹ Over time, this original system has been extended to allow communication of music, mathematics, and computer code to readers without vision. Basic Braille uses an array of six dots to represent letters and numbers. Traditional Braille, however, is usable only for static text, such as printed books. Dynamic information cannot be represented by raised dots on a sheet of paper.

Technology access requires the use of refreshable Braille. Refreshable Braille displays use a set of piezoelectric pins to represent Braille letters. Changing electrical signals to the display moves the pins up and down, thereby allowing a single display to represent different portions of a longer document.

Braille is not widely used by individuals who are blind.⁹ By some estimates, only 10% of the blind population know and use Braille. It is not usable, for example, by those who have limited tactile sensation, as well as blindness. Since the largest group of blind individuals in the United States consists of those with diabetic retinopathy, which is probably matched to peripheral neuropathy affecting touch, a large proportion of blind individuals are not able to use Braille. Nonetheless, Braille is a skill that should probably be taught to a person who is blind, provided that the person has adequate sensation. Most Braille readers are employed. Most people who are blind but do not read Braille are not employed. Although Braille may not be an essential skill for employment, the ability to learn Braille certainly correlates with the ability to hold a job.⁹

Threaded Case Study Gianna, Part 2

Gianna has difficulty in her current areas of occupational performance in instrumental activities of daily living, education, and social participation, which might be addressed through assistive technology. She will continue to have deficits in her activities of daily living that will not be addressed through assistive technology. Through the use of an EADL, Gianna can gain control over her immediate environment. She will be able to control the temperature of her home, the radio, and/or television; control the lighting; and open doors as desired. Her verbal communication skills are excellent, but her ability to write letters to friends (graphic communications) would benefit from the same technologies (primarily mobility [not addressed in this chapter] and computer access) that will allow her to pursue her education. Although Gianna can write and print papers, she will not be able to hand them in without assistance unless her professors allow electronic submission.

In view of Gianna’s level of motor control, she might consider head pointing, Morse code, or speech recognition as a means of controlling her assistive technology. All of these technologies can be applied to computer control and to her EADL. Careful assessment by her therapist would determine which control strategy best meets her needs and whether the same control strategy would work for all of her assistive technology applications.

Depending on the input method selected, Gianna might benefit from word prediction and abbreviation expansion for her text input. Since her vision and hearing are not affected, no changes in the output systems of her computer would be necessary.

Through the application of appropriate assistive technology, it becomes possible for Gianna to have more control over her life in terms of both her immediate surroundings and her future occupations. Gianna will be able to access online resources, write papers for college, and ultimately, if she has the cognitive skills, become a successful lawyer. Her assistive technology does not guarantee that Gianna will succeed, but it does give her the same opportunities to succeed or fail that her peers without functional limitations enjoy.

Summary

An OT should always keep in mind that disability makes few things impossible. It does make many things harder and some sufficiently hard that they are “not worth it.” Assistive technology can make many things easier for the person with a disability. Because they are easier, many things that were previously not worth the effort can become reasonable activities for a person with a disability. Assistive technology will never, in the terminology of the model of disability, remove the functional limitation. It can, however, prevent that functional limitation from resulting in a disability.

Review Questions

1. Compare and contrast rehabilitative and assistive technologies.
2. In what way do devices using universal design assist individuals with disabilities? Why aren't they considered to be assistive technologies?
3. According to the HIA model, why might a person with a disability not require any assistive technology for the completion of some tasks?
4. In pediatric applications, complex EADL devices might not be considered appropriate. What sort of EADL might be used with a very young child?
5. Some EADL devices allow control of the features of devices in the environment. Discuss the benefit of providing such control. What additional load does this place on the user?
6. AAC devices can be used to provide alternative or augmentative communication. Discuss the difference between these two strategies. Might an AAC device be a rehabilitation technology in some applications?
7. What is the value of having a message composition area that is independent of the message transmission feature of an AAC device? Discuss the value for the communicator and for the communication partner.
8. Discuss the difference between “conversation” and “formal presentation.” How might each of these be important in an educational setting? What are the dominant demands of each type of communication?
9. How does a language disorder differ from a communication disorder? What sort of AAC device would help a person with a language disorder?
10. If an individual is able to use a physical keyboard but is able to use only one hand, what keyboard options might help him or her with text production?
11. Consider the keypad providing control for a microwave oven. How might the keypad present difficulty to an individual who is blind? How might it be modified by an OT to improve its usability?
12. Word prediction and word completion are often touted as means to improve typing speed, yet research suggests that it does not. What advantage might these

technologies offer to improve productivity for a person with a disability?

13. Abbreviation expansion is generally considered a means of typing long words and phrases with only a few keystrokes, although this requires the user to remember the abbreviation. How else can this technology be used for individuals with learning disabilities in ways that do not require memorization of keystroke sequences?
14. Refreshable Braille is expensive, whereas text to speech is quite inexpensive. Yet Braille training is mandated by the IDEA. What factors support learning this old technology by individuals who are blind?
15. Integrated control systems will allow a single control device to serve as the interface to a range of assistive technologies. What are the advantages of integrated control systems? Why might an integrated control system not be desirable for an individual user?

Performance Skills: Definitions and Evaluation in the Context of the Occupational Therapy Framework

■ Chapter Outline

The Occupational Therapy Practice Framework-2
Connection of performance skills and client factors with occupational performance
Occupation-based approaches and neuroscientific evidence
Performance skills and client factors
Motor control theory
Neuroscience research related to practice
Best practice occupational therapy service
Summary

■ Key Terms

Adaptive plasticity	Motor control theory
Client factor	Neuroplasticity
Contrived	Occupational performance
Control parameter	Performance skill
Cortical reorganization	Plateau
Function	Strategy
Impairment	Task-oriented approach

■ Learning Objectives *After studying this chapter, the student or practitioner will be able to do the following:*

1. Describe the difference between a performance skill and a client factor.
2. Explain client-centered occupation-based performance.
3. Relate how improvements in performance skills may influence habits, roles, and routines.
4. Define impairment, strategy, and function.
5. Identify principles that may affect client outcomes.
6. Explain how a skilled intervention with clients facilitates cortical reorganization.

The Occupational Therapy Practice Framework-2

The revised Occupational Therapy Practice Framework-2 (OTPF-2) was designed to guide occupational therapy practice and to convey to others the complexity of the profession.¹ The revisions were offered to “refine the document and include language and concepts relevant to current and emerging occupational therapy practice” (p. 625). This chapter will review the connection of performance skills and client factors as applied to a client case presentation.

Connection of Performance Skills and Client Factors With Occupational Performance

Performance skills and client factors influence a client’s occupational performance. **Occupational performance** is engagement in meaningful and purposeful activities that relate to habits, routines, and roles. Active client engagement in occupation-based evaluation and intervention can facilitate changes in performance skills and performance patterns, which may influence habits, roles, and routines, and ultimately occupational performance. This chapter will address how these elements relate to any client throughout

Threaded Case Study John

John is a 50-year-old construction worker who has been out of work for 1 year. Most recently, he has been keeping the house while his wife continues to work full time. He lives with his wife and two children, ages 10 and 15. He has sustained a right MCA (middle cerebral artery) CVA (cerebral vascular accident). The resultant deficits from this CVA include hemiparesis in his left lower extremity with mild **impairment**, and in his left upper extremity with moderate impairment, with greater impairment in distal motor control compared with proximal motor control. His movement patterns in his left upper limb include lifting his shoulder and bending his elbow to position his hand so that it is better able to pick up items, but he is able to use only gross grasp and has limited precision for release of objects with his left hand. He presents with a left visual field deficit and decreased sustained attention. He requires occasional indirect verbal cues to attend to tasks and activities. He benefits from the use of strategies to compensate for his deficits. He is currently able to complete all basic self-care activities with occasional to minimal assistance. Much of the physical assistance required involves starting the activity and enhancing quality of performance. He is medically stable and is taking antiseizure medications. He is right hand dominant.

John lives in a one-story ranch home with no steps inside the house. He is currently walking with the use of a wide-based quad cane. He and his family live in an urban setting with access to public transport. Numerous friends and family members live nearby. His children participate in several after-school activities that require one parent to pick them up from school and return home. His wife has been picking up the children over the past year because her workplace is located near the children's school.

John wants to improve his home management skills and to maintain his role as a homemaker in support of his wife. He has asked that the occupational therapy practitioner focus on helping him to be able to complete his morning routine, take his medications, and manage the home. He is currently unable to complete stove-top cooking activities and has difficulties with vacuuming the carpet and sweeping the floors in the house. He also is unable to complete shaving activities as he did before the CVA. Before the CVA, John used a safety razor in his right hand and held a portion of his face with his left hand to allow the safety razor to smoothly glide over the skin of his face without cutting or nicking the skin. Following the CVA, John uses an electric razor, held only in his right hand, but he does not like the poor results and often has razor irritation following shaving. He is unable to use his left hand to assist in the process of shaving.

the lifespan and will describe how neuroscientific research suggests that an occupation-based approach can facilitate changes in the central nervous system that directly correlate with improvements in occupational performance and client-centered outcomes.

The importance of client-centered interactions in the selection of specific occupations as a means to helping clients progress through the occupational therapy (OT) process is a concept endorsed by the American Occupational Therapy Association (AOTA)¹ and several leaders in the OT profession.^{7,9,16,24} This process may occur in various ways—via the Assessment of Motor and Process Skills (AMPS),⁷ an occupational functioning model,²⁴ or a task-oriented approach¹⁶; in all cases, the message is similar. Analysis of client performance provides the OT practitioner with a means by which to understand what is observed. These authors identify with a common thread consistent with the World Health Organization definition and classification of disability²⁶: that performance analysis is important. This analysis may be formal or informal. One particular caution is to make sure that during any informal analysis, the intended outcome is specifically identified. This will allow the OT practitioner to anchor what was expected with what is actually performed and observed. Thus, the focus remains on the tasks and corresponding performance skills; the client factor does not serve as the key determining variable in the OT process.

Occupation-Based Approaches and Neuroscientific Evidence

Connecting occupation-based approaches to the neuroscientific realm provides a framework by which to consider these concepts as they relate to learning. Learning, as defined in this context, theoretically occurs as a result of neuroplasticity, and it is assumed that new neuronal connections and axonal sprouting occur within the central nervous system through multisensory input.²³ Application of this concept may be seen with clients who have sustained upper motor neuron (UMN) injuries. Current trends in occupational therapy to ameliorate upper extremity hemiparesis as a result of UMN lesions are varied, yet research indicates that a potentially beneficial way to achieve a successful client-centered outcome is to include those interventions that address how the client interacts with the task and the environment.²⁵ This particular approach is supported by basic and applied neuroscience concepts that imply that skilled interaction associated with a client's task performance in a particular environment may direct cortical changes and facilitate neuromuscular recovery. Consequently, this type of approach may improve completion of activities of daily living (ADLs) by improving performance skills¹¹ via engagement in occupational performance-based activities. Occupational performance, as such, often is observed when a person performs a particular task in a particular environment.²⁷ This dynamic interaction among the individual, the task, and the environment is consistent with the foundational framework provided by the **task-oriented approach** (TOA).¹⁶

The TOA is one of a variety of approaches to evaluation and intervention that incorporates an underlying understanding of a variety of concepts. Among these is the
