DISCLAIMER

When citing chapters from this book, please use the appropriate form. The APA format is as follows:

[Chapter author last name, I.] (2009). Chapter title. In E. B. Crepeau, E. S. Cohn, & B. A. B. Schell (Eds.), *Willard and Spackman's occupational therapy* (11th ed., pp. x – x). Philadelphia: Lippincott Williams & Wilkins.

Dickie, V. (2009). What is occupation? In E. B. Crepeau, E. S. Cohn, & B. A. B. Schell (Eds.). *Willard and Spackman's occupational therapy* (11th ed., pp. 15 – 21). Philadelphia: Lippincott Williams & Wilkins.
Colonel Brandon to Miss Dashwood:
"What can it do?
Give me an occupation or I shall run Mad!"

JANE AUSTEN, *Sense and Sensibility*

Dedication

**Helen Hopkins, Ed.D, OTR, FAOTA and
Helen D. Smith, MS, OTR, FAOTA**

Co-Editors, Willard and Spackman's Occupational Therapy 5th through 8th editions

Helen Hopkins and Helen D. Smith edited the 5th through the 8th editions of *Willard and Spackman's Occupational Therapy.* Helen Hopkins was a founding member of the Occupational Therapy Department at Temple University. She chaired this program for many years prior to her retirement in 1986. Helen Smith was a long time faculty member at Tufts University—Boston School of Occupational Therapy retiring in 1998. The two "Helen's" were both dedicated and caring teachers who were deeply committed to the learning of their students. They were equally dedicated to occupational therapy. For many years we could count on seeing them together at the AOTA Annual Conference. Whether talking to and sharing stories with former students, *Willard and Spackman* contributors, or to their many colleagues, they always were encouraging and thought provoking. Even after passing the editorship of *Willard and Spackman* to their successors, they remained interested in the evolution of the book and supportive of our work as editors. We are grateful for their many years of service and dedicate this edition to them to honor their contribution to the profession.

Preface

Willard & Spackman's Occupational Therapy has a long tradition that extends back to the 1st edition published in 1947. Helen Willard and Clare Spackman, colleagues who taught together at the Occupational Therapy Program at the University of Pennsylvania, co-edited the 1st through the 4th editions. They turned the editorial responsibilities over to Helen Hopkins and Helen Smith, faculty members at Temple University and Tufts University, respectively. They edited the 5th through the 8th editions. Maureen Neistadt and Elizabeth Crepeau, faculty colleagues at the University of New Hampshire, edited the 9th edition and began work on the 10th edition. After Maureen's death, Ellen Cohn at Boston University and Barbara Schell at Brenau University joined Betty in editing the 10th and this edition.

We revised and updated the 11th edition to highlight the advances in knowledge in occupational therapy and occupational science in the past five years. This edition includes significant changes in both the scope and nature of content from the 9th and 10th editions. These changes are derived from the evolution of the field, results of surveys of faculty and students using the book, and three focus groups of occupational therapy students, occupational therapy faculty, and occupational therapy visionaries held during the 2004 AOTA Annual Conference in Minneapolis, Minnesota. Information from these sources indicated that people use the book to gain a broad understanding of the field and for its encyclopedic content. We were encouraged to include more information about occupational science and the occupational nature of human beings and to provide a more international perspective of the field. In addition to providing a broad overview of the profession, we were urged to include a critical perspective, examining the profession relative to whose interests were being served (and whose overlooked) by the field's current practices. We also discovered that the pediatric and adult units of the 10th edition were less important to readers, most likely due to the emergence of many more specialized texts in occupational therapy. Readers also appeared to be using different resources for theories other than occupation-based theories. Our revision incorporates these observations and

recommendations. In this edition, we have attempted to balance the tradition of the encyclopedic function of *Willard & Spackman* as the "place to start" while providing sufficient depth in coverage of topics critical for an introductory text.

This new edition of *Willard & Spackman's Occupational Therapy* is structured to make navigation through the text easier. This has been accomplished by

1. The new sequence of units;
2. The elimination of multi-section chapters;
3. The integration of theory, evaluation, and intervention into single units; and
4. The addition of specific resources for common conditions and practice settings.

Additionally, this edition reflects trends in the field regarding the centrality of occupation as the basis for practice. Finally, there is more explicit attention to the influence of the broader social and political environment on participation in the day-to-day lives of people.

Units I–II introduce readers to the concepts of occupation, the personal narratives of people with disabilities, and the relationship of society to occupation. This organization of chapters places important core concepts of occupation early in the book as the foundation for understanding occupational therapy practice. Feedback from the 10th edition indicated that Mary Feldhaus-Weber's chapter (*The Book of Sorrows, Book of Dreams*) was very effective. Mary's first person account vividly describes her personal experience with acquired brain injury, making her story accessible to readers who may have little understanding of what it may be like to live with a disability. Building on this success, Unit II includes six new chapters beginning with a brief overview of narrative theory. Subsequent chapters provide first person accounts from three different individuals. The first chapter is Mary's account of living with acquired brain injury; the second chapter describes growing up with cerebral palsy from the perspective of the child (now a young adult) and his parents; and the third chapter is the narrative of a person living with chronic mental illness. The caregiver perspective is represented in a fourth

chapter. The unit closes with two chapters from international authors reflecting community-based occupational therapy practice that involves the development of client narratives as a way of promoting understanding and change.

Unit III: Occupation and Health in Society addresses important social and health policy issues, health promotion, community integration, and occupational justice. These chapters provide background information promoting the broad societal responsibilities of the occupational therapy profession. These chapters support the ideal that every individual has a right to be able to meet basic needs and to have equal opportunities and life chances to reach toward her or his potential through engagement in diverse and meaningful occupation

Unit IV: Profile of the Occupational Therapy Profession begins with a review of the history of the profession and then provides the reader with an overview of contemporary occupational therapy practice. The remainder of this unit consists of new chapters: one provides an overview of occupational therapy practice in the world, a second chapter addresses the organization of the profession within the USA, and a third chapter describes concepts of professional competence and competency. A substantially revised chapter on fieldwork is placed in this unit as well. The final chapter in this unit provides a critical perspective of occupational therapy practice today.

Units V through IX introduce readers to the building blocks of practice from content related to the values and beliefs of the profession itself, to the core reasoning and analytic processes inherent in practice. In addition to substantially updated chapters about occupational analysis, interviewing, and teamwork, new chapters address therapeutic relationships and communication with clients as well as professional communications and presentations. Unit VIII: Conceptual Basis for Practice includes expanded chapters on the major occupation-based theories, emphasizing the centrality of occupation as the core of practice.

Units X through XII introduce readers to occupational therapy evaluation and intervention in relation to occupations, personal factors, and the environment. Each chapter reviews relevant theoretical perspectives and integrates these perspectives with evaluation and intervention processes, demonstrating the integrated nature of practice. These chapters provide examples of evaluation and intervention of clients which cross the life course as well as the continuum of occupational therapy practice. Authors provide a summary of important evidence guiding practice as well as a critical analysis of gaps in the available evidence. A new chapter addressing personal factors provides a list of body functions and structures useful in prompting consideration of the many factors affecting performance.

Unit XIII: Therapists in Action: Examples of Expert Practice is entirely new, taking a narrative perspective of occupational therapy practice from the point of view of expert practitioners discussing their work. This unit provides insights into the professional reasoning of expert practitioners and helps readers understand the challenges and complexities of occupational therapy practice in different practice settings, including school-based practice, shelters for people who are homeless, long term care, and outpatient medical settings.

Unit XIV: Managing Practice addresses basic management principles in occupational therapy practice. All new chapters in this section address basic management functions, including supervision with specific attention to occupational therapists, occupational therapy assistants, and aides. An overview of payment for services describes the many options for payment and provides the context for understanding reimbursement structures in the USA. The final chapter on consultation brings the insights of current practitioners to readers who may consider this form of practice.

Unit XV: Common Conditions: Related Resources and Evidence includes brief summaries of many common conditions seen in occupational therapy practice with basic information about signs and symptoms, diagnostic criteria, medical/social interventions, occupational therapy evaluation and intervention, review of the evidence supporting practice, and caregiver considerations. Additional resources are listed for further reading. Information about additional conditions are posted on the *Willard and Spackman* website.

Unit XVI: Occupational Therapy Resource Summaries: Practice Settings provides a basic overview of the various settings in which occupational therapy practitioners provide services. This overview is in an accessible table format, including descriptions of settings, clients, length of stay, reimbursement mechanisms, etc. Units XV and XVI provide readers with a "place to start"—a characteristic of the book we felt was important to retain.

Unit XVII: Table of Assessments returns and includes all assessment instruments mentioned in the chapters in the book in alphabetical order by title. This resource contains information about the assessment, including author, purpose, age range, areas assessed, and publisher information.

The **Glossary** includes definitions of key words from chapters and important terminology from the August 2007 draft of the 2nd edition of the Occupational Therapy Practice Framework.

This edition includes the terminology of the International Classification of Function and the draft versions of the 2nd edition of the Occupational Therapy Practice Framework. At the time this book went to press the Framework was still under review, consequently some of our terminology may not reflect the final version.

Because we are aware of the power of language to influence the way we think, we have attempted to be as inclusive as possible in the descriptors of individuals. To the extent possible, we used the term occupational therapy practitioners to represent the certified occupational therapist and certified occupational therapy assistant.

We have tried to avoid language that exhibits bias and labels people with disabilities. We have used nonmedical language to the extent that this was appropriate.

Throughout the book are special features that expand and extend the text of the chapter. In addition to case studies and Practice Dilemmas, readers will find Commentaries on the Evidence, Ethical Dilemmas, and Provocative Questions to foster greater processing of the material in the book. The companion website to this book has additional supports for learning, including PowerPoint presentations, class-based and out of-class learning activities, case studies, and figures from the book suitable for use by instructors for class activities.

We are grateful to our many colleagues who have given us feedback about the 10th edition. Our efforts have been to create a book that represents the best aspects of our field—and that reflects positively on the important heritage of this book. The former editors and the current and former contributors have provided a strong foundation for us to build upon. It is our hope that this edition honors the past and provides a pathway for future generations of occupational therapy practitioners.

Acknowledgments

This edition of *Willard & Spackman* was accomplished through the collective efforts of the contributors, focus group members, editorial review board, photographers, students, colleagues, friends, and family. Well over 120 people have directly contributed to the development of this book. We are grateful for their many contributions to this effort and know that their generosity has improved the quality of the work presented here. We are pleased that Anne James agreed to take on the role of editor for web-based instructional materials and are thankful for her work in expanding the horizons of this text into the virtual context of cyberspace.

Our work as a team has also been essential to the development of the book. We have engaged in many conversations about the structure of the text, the content, how to approach issues which lack agreement in the field, and how to represent the breadth, scope and depth of the evolving knowledge base of the field. This work did not go on in a vacuum, but was enmeshed in our day-to-day lives of our families, our work, and our community involvements. The past 5 years have brought new grandchildren: to Betty (Naomi, Owen, and Theo) and Barb (Samarra and Akhasa). Ellen's girls have become vibrant and mature young women, participated in national and international synchronized skating competitions. Adrienne has gone off to college and Maggie started driving. We have experienced the challenges of receiving health care and the benefits of competent rehabilitation services when Betty had both knees replaced, Barb received a new hip and Ellen worked to restore an injured knee. Our husbands have tolerated our time spent on this book far more patiently than we could ever expect. In the midst of already full professional and personal lives, we have practiced what Elizabeth Larson refers to as occupational orchestration as we worked on this book. Sometimes this orchestration has required us to withdraw from some valued occupations to which we plan to return—Betty to her garden, knitting, and sewing, Ellen to the courts, trails, roads and beaches, and Barb to her golf, artwork, and walks with the family dogs. None-the-less, editing this book has been a privilege. We have worked with contributors equally devoted to sharing their knowledge of the field with the next generation of occupational therapy practitioners. Our relationships with the contributors have brought us into contact with some of the leading scholars in the field which has enriched our understanding of the changes in the field and the challenges we face in the future. We thank all who have supported us and who have contributed to this endeavor and hope that our efforts to represent these contributions live up to the fine tradition the *Willard & Spackman* has in the field.

While working on this book has been a serious undertaking, the infusion of humor has lightened the load. Like many cohesive teams, we have developed slogans and catch phrases that are a way for us to mark special issues and moments. Some of these include

- *Putting the hay down where the goats can get it*—This phrase was a reminder to remember our primary audience, occupational therapy students, and challenged us to make complex topics relevant and accessible to them.
- *The horses are smelling the barn*—This phrase refers to the fact that as horses approach home, they speed up because they know that food and water will be available in the barn. We chanted the phrase when we reached important milestones in the book such as completion of the initial book proposal, critical chapters or units, etc.

- *PIGASI (Paint it gray and ship it)*—This nonsensical phrase we adopted from Linda Duncombe of Boston University. It reminded us that while we wanted everything in the book to be perfect—sometimes we just had to PIGASI.

We thank those listed below for their generous assistance in helping us conceptualize this book and bring it to fruition.

Photographs and Historical Documents

Professional Colleagues and Students

With gratitude and appreciation, we acknowledge our colleagues at Boston University, Brenau University, and the University of New Hampshire for their assistance, support, insightful feedback, and willingness to listen to endless conversations about *Willard & Spackman*

Boston University

- Sue Berger, Sharon Cermak, Wendy Coster, Linda Duncombe, Karen Jacobs, Nancy Lowenstein, Deane McCraith, Naomi Moran, Gael Orsmond and Elsie Vergara
- Patricia Nemec for recommending Gloria Dickerson as an author
- Occupational therapy students: Pamela Errico, Christine Hegarty, Brooke Howard, and Kate Runge
- Rebecca Hanson for outstanding attention to detail, proofing, and conceptual clarity
- HP 870: Theory and Research in the Health and Rehabilitation Sciences graduate seminar students, Spring 2005

Brenau University

- Faculty colleagues M. Irma Alvarado, Lori Andersen, Sara Brayman, Mary Shotwell and Robin Underwood,
- Classes of 2007 and 2008

University of New Hampshire

- Kasey Dutra, Kristy Golt, Meredith Grinnell, Christine Leonard, Hilary Maynes, Amanda Neill, Kate-Lyn Stone,
- Classes of 2007 and 2008
- Sajay Arthanat, Lou Ann Griswold, Susan Merrill, Shelley Mulligan, Douglas Simmons, Elizabeth Stewart, Barbara Prudhomme White, Kerryellen Vroman, and Therese Willkomm

Lippincott Williams & Wilkins

- Current and former Lippincott Williams and Wilkins personnel contributed to the development of this book
- Pamela Lappies, Susan Katz, Nancy Peterson, Emily Lupash, and Matt Hauber
- Laura Horowitz of Hearthside Publishing Services provided overall guidance of the development of the manuscript through the production of the book. Her steady guidance, expertise, patience, and good humor provided significant support to our efforts.
- Gina Aiello and Eve Malakoff-Klein, production editors, who collaborated with us in the final steps of transforming the manuscript to finished text.
- Barbara Willette, copy editor, whose careful work caught our confusing language, misplaced commas, and errors in APA format.
- Gelya Frank at the University of Southern California inspired our epigraph.

Provocative Questions

I

OCCUPATIONAL SCIENCE AND THE OCCUPATIONAL NATURE OF HUMANS

" I believe that the ordinary rhythm of daily living is the deep primordial nourishment of our existence. It is the "truth"—the primary reality for each one of us. After all, everyday occupation is present in our lives at *all* times and in *all* places. "

Betty Risteen Hasselkus

The Making and Mattering of Occupational Science

1

FLORENCE CLARK AND
MARY C. LAWLOR

Learning Objectives

After reading this chapter, you will be able to:

1. Describe the recent history in the development of occupational science.
2. Demonstrate an understanding of the domains of concern of the discipline of occupational science.
3. Discuss the linkages between occupational science and occupational therapy.
4. Identify ways in which knowledge generated through research in occupational science informs occupational therapy practice.

Occupational science has been described as both an emergent discipline (Molke, Laliberte-Rudman, & Polatajko, 2004; Wilcock, 2001; Yerxa, 1993; Yerxa et al., 1989) and an evolving discipline (Zemke & Clark, 1996a). Even though the discipline of occupational science is still in its infancy, compared to other more established disciplines, a number of exciting developments both illustrate the shape the field is taking and foreshadow future possibilities. In this chapter, we discuss the nature of this discipline, describe its evolution, analyze the interrelationships of occupational science and occupational therapy, and provide evidence of the contributions of the discipline to occupational therapy. We also discuss how an understanding of occupational science, including the recent history of the field, informs and influences innovative occupational therapy practice.

The name of the discipline itself warrants further unpacking, as both the terms *occupational* and *science* have been the focus of much consideration and, at times, debate. Words matter. Although these words might seem self-explanatory, the interpretations of the meanings continue to influence understandings. In the following passages, we will frame the defini-

tional issues and the implications for future development. Occupational science was grounded in the interdisciplinary social sciences and continues to sustain interrelationships with a number of these disciplines, including sociology, anthropology, philosophy, and psychology. As the discipline has evolved, new and productive conceptual and practical linkages have been formed with disciplines in other academic traditions, including neuroscience, biology, preventive medicine, rehabilitation science, gerontology, biomedical engineering, public health, and physiology. Occupational science is also recognized for its unique relationship with occupational therapy and, in a more general way, the remarkable success of this young discipline in navigating the intersection of academic disciplines and practice professions. This achievement marks occupational science as a new form of discipline, a discipline that is poised to facilitate the application or translation of new knowledge and theory into efficacious solutions to real-world problems.

DOMAINS OF CONCERN OF OCCUPATIONAL SCIENCE

Definitions are designed to clarify what something, in this case occupational science, is or means. Although definitions can be helpful, they tend to oversimplify the nature of a discipline, its domains of concern, and perhaps more important, what a discipline does, the utility of a science, the ways in which a science addresses the needs of society. As we describe later in this chapter, occupational science now has a global presence and at local and national levels there is considerable diversity in the defining or foregrounding of characteristics as scholars and practitioners adapt theoretical assumptions to the needs of local societies.

Definitions can provide a snapshot of the domains of concern of a discipline. Taken collectively, definitions also offer insights into a range of perspectives that relate to the identification of the most salient dimensions of the field. Occupational science has been defined as "a basic science devoted to the study of the human as an occupational being" (Yerxa, 1993, p. 5) and, similarly, as "the rigorous study of humans as occupational beings" (Wilcock, 1998, p. 257). The phrase *occupational science* is most often approached by defining the terms *occupation* or *occupations.* One of the earliest and most cited definitions is as follows: "chunks of culturally and personally meaningful activity in which humans engage that are named in the lexicon of the culture" (Clark et al., 1991, p. 4). Occupation has also been described as "a synthesis of doing, being, and becoming" (Wilcock, 1999, p. 3).

Yerxa (1993) placed issues of skill development, holism, and experience in the foreground in describing the founding principles of occupational science. Occupational science addresses the centrality of engagement in occupations and in human life, particularly as they relate to health and well-being, and social participation. Concep-

tualized broadly as the activities that constitute everyday experience, occupations include the kinds of purposive activity that make up people's lives, such as activities of daily living, interpersonal activities, physical activities, restorative activities, and social and cultural practices. Because occupations are so far ranging, they are conceived as crossing the spectrum of human needs and desires from survival and reproduction to economic subsistence, participation in social life, and artistic and spiritual expression (e.g., Wilcock, 2005; Yerxa et al., 1989; Zemke & Clark, 1996a, 1996b). But the focus of occupational science is not only on the activity per se, but also on the social actors who are engaged in occupations within the social, cultural, and historical particulars of their lived world— in essence, how people live and learn in everyday life; the relationships among activity, participation, and health; and how social engagements and social structures afford and constrain health, participation, quality of life, and human experience (e.g., Dickie, Cutchin, & Humphry, 2006; Farnworth, 1998; Hocking, 2000; Lawlor, 2003; Molineux & Whiteford, 1999). In accord with this perspective, occupational science might be thought of as addressing the variety of ways in which people are occupied as human beings and the impact that such engagement has on bodies, selves (Abbott, 2004),[1] communities, and the world.

METHODOLOGICAL APPROACHES

Modes of inquiry and methodological approaches in occupational science have developed in ways that reflect the evolving nature of the discipline and the strengthening of the interrelationships between occupational science and occupational therapy. When occupational science was established, efforts were devoted to differentiating this science from traditional, positivistic approaches that relied on experimental paradigms to generate knowledge and test theory (Zemke & Clark, 1996b). There appeared to be a natural affinity between research questions in occupational science and qualitative, phenomenological, and narrative modes of inquiry (Gray, 1997; Hocking, 2000; Lentin, 2002; Mattingly & Lawlor, 2000; Wicks & Whiteford, 2003). Although these approaches have produced new

---

[1]This statement draws on a quote from Dr. Andrew Abbott's paper "Creating an Academic Discipline That Supports Practice," which was presented at the 16th annual Occupational Science Symposium at USC on January 16, 2004. In his thoughtful and provocative paper, Dr. Abbott argued that the discipline should develop by moving : "towards organizing occupational science around a general theory of the immediate daily activities with which we occupy our bodies and ourselves" (p. 12). We are deeply indebted to Dr. Abbott for his scholarship, including his other published work, and we continue to be influenced, intrigued, and challenged by his insights.

knowledge and enhanced theory development, they only partially represent the range of methodological approaches that are inherent in occupational science research.

In their efforts to generate new theoretical understandings of the occupational, social, cultural, political, and historical dimensions of participation in everyday life, occupational scientists have expanded methodological approaches to studying occupation and its relationship to health and social participation. Occupational science is designed to systematize knowledge about occupation, especially in relation to health and well-being. In addition, occupational scientists are collaborating with scholars in other disciplines to provide methodological and theoretical support in interdisciplinary research programs where issues related to understanding engagement, activity, participation, experience, and health provide unique challenges. The study of occupations requires complex analytic frames to capture the multifaceted aspects of occupations, particularly in naturalistic settings. As Glass and McAtee (2006) have argued, understanding relationships between behaviors and health requires a contextual orientation that is multidimensional, examining individual and distal social features, biological features on multiple levels, human action, and other characteristics across time. The *science* of occupational science is grounded in multiple methods and reflects a recent trend to avoid differentiation of research into the overly simplistic categories of basic and applied (e.g., Flyvberg, 2001).

One of the most significant developments in occupational science is the development of new methods that are scientifically rigorous, span the continuum of paradigms from ethnography to randomized controlled trials, and facilitate translation into practice. In addition, occupational scientists have designed research programs that evaluate and utilize mixed method approaches in innovative ways. These developments combine both conceptual approaches to inquiry and the application of new technologies in research endeavors. Later in this chapter, we provide exemplars of this work, drawing on the University of Southern California (USC) Well Elderly Study and USC/Rancho Los Amigos National Rehabilitation Center Pressure Ulcer Prevention Study (PUPS).

THE GROWTH OF OCCUPATIONAL SCIENCE

Although occupational science is a mere 18 years old, there is no doubt that it is flourishing. In this short period of time, more than 45 scholars have received their PhD degrees in occupational science at USC alone, and most of them are now in academic leadership positions in the United States and worldwide. Furthermore, 20 occupational therapy academic programs have been renamed to include occupational science in their titles. Consistent with this trend, several programs now offer degrees at various

levels in occupational science. For example, Towson State University now awards a ScD in Occupational Science, the University of North Carolina (UNC) and USC grant the PhD in the discipline and a joint MSc/PhD in Occupational Science can be earned at the University of Western Ontario. Other colleges and universities have chosen to offer occupational science undergraduate major and minor programs that aimed at providing a strong foundation for entry into occupational therapy professional programs. In total, 20 programs throughout the world are identified as occupational science university programs (www.jos.edu.au). Finally, founded at the University of South Australia in 1993, first as the *Journal of Occupational Science: Australia* (JOS:A), the *Journal of Occupational Science* (JOS) is now in its 15th year of publication. Unlike journals that have the words *occupational therapy* in their title, JOS is dedicated to publishing articles about humans as occupational beings and has a policy that bars publishing manuscripts that are strictly focused on therapy (Wilcock, 2003).

Arguably, one of the most impressive aspects of occupational science is the magnitude with which it has taken root internationally (Clark, 2006; Hocking, 2000; Mounter & Ilott, 1997, 2000; Wilcock, 2005; Yerxa, 2000). In 1999, just 10 years after the founding of the discipline, the International Society of Occupational Scientists (ISOS) was established by 32 occupational scientists who wished to further the discipline by building international bridges. The aims of ISOS are designated on its Website (http://isos.nfshost.com/aims.php) as follows:

- ◆ To promote study and research of humans as occupational beings within the context of their communities and the organization of occupation in society
- ◆ To disseminate information to increase a general understanding of people's occupational needs and the contribution of occupation to the health and well-being of communities
- ◆ To advocate for occupational justice internationally
- ◆ To encourage a range of disciplines to consider and frame their own research from an occupational perspective so they may expand their influence on sociocultural, political, medical, environmental, and occupational processes

Soon after ISOS was established, national or regional societies began to be formed that were modeled to a considerable extent on ISOS but also were tailored to address the priorities of each one's particular stakeholders. Table 1.1 lists the Website addresses and founding dates of the 10 organizations and societies worldwide that have as one of their chief aims furthering occupational science. As the table reveals, these organizations are relatively new, all having been established between the years 2000 and 2006. The various Websites provide a broad-based sense of the commonalities shared by these organizations and the differences in their focuses. While all of the organizations

have as primary aims promoting research on occupation, particularly as it relates to health, they differ in the degree of emphasis they place on other aims such as multidisciplinarity, promoting social justice, or linking occupational science to occupational therapy. A promising new development is that in 2006 and 2007, two international Think Tanks were held, the first in Australia (Wicks, 2006) and the second in the United States, with representatives from as many as 14 countries and five continents, most of whom were from the organizations listed in Table 1.1, to explore the ways in which the various organizations might relate with one another and support ISOS. The key result of the Think Tanks was the unanimous decision to move forward in seeking affiliative relationships among the organizations and in supporting ISOS as a potential umbrella organization.

Another indicator that occupational science is flourishing is the number and quality of scientific symposia that are being held. For 19 consecutive years, an annual occupational science symposium has been held at USC featuring over 100 presentations on interdisciplinary occupational science–related themes and relevant research. These symposia have typically included presentations from world-renowned scientists, philosophers, and scholars. Among the most eminent presenters have been primatologist Jane Goodall, neuroscientist Antonio Damasio, sociologist Andrew Abbott, rehabilitation scientist Margaret Stineman, neuroscientist Candace Pert, philosopher John

Searle, psychologist Mihaly Csikszentmihalyi, psychologist Jerome Bruner, anthropologist and linguist Mary Catherine Bateson, and physicist Stephen Hawking.

As scientific societies have been established throughout the world devoted to furthering occupational science, they too have held annual symposia. Between 2000 and 2007, 18 such symposia were convened. Collectively, these symposia (including those held at USC in this time period) have included over 300 presentations, with speakers from over a dozen countries. It is interesting to note the most frequently addressed topics included occupation and health, occupation and the environment, cultural influences on occupations, occupational justice, time use, work, arts and creativity, parenting, and the importance of everyday activities. The populations that were most frequently addressed were women; individuals with chronic illnesses or disabilities; and infants, children, and adolescents. People who are homeless, inmates and ex-inmates, college students, individuals identifying as gay, lesbian, bisexual, or transgender, and refugees and immigrants were also participants in occupational science research presented at these symposia.

Finally, perhaps the key indicators of the vitality of occupational science are the number and the quality of papers that its scholars produce annually in peer-reviewed journals. These benchmarks, of course, are difficult to track thoroughly for several reasons. First, papers that occupational scientists produce are often not identified in

databases as occupational science. Second, it is difficult to develop criteria for inclusion of articles as occupational science. Third, certain publications in occupational science are authored by non–occupational scientists and/or are published in journals that are not affiliated with occupational therapy. Additionally, occupational scientists might publish their work in interdisciplinary journals without indicating in the manuscript that their study or piece of scholarship is occupational science.

Nevertheless, two studies have recently been undertaken that identify publication trends in occupational science. Molke, Laliberte-Rudman, and Polatajko (2004) focused on the years 1990 and 2000 to detect changes in publication patterns between these two points in time. To be included in the study, the publications had to meet the following criteria: (1) the phrase *occupational science* or *science of occupation* was in the title, identified as a key word in the abstract, or in a collective title, and (2) the publication was not a book review, letter to the editor, or workshop summary. The authors found that only 10 publications qualified in 1990 (one year after occupational science had been founded) but that in 2000, 44 papers were identified, a fourfold increase. Moreover, in the second time period, there was a pronounced expansion in the number of authors from countries other than the United States compared to the author pool in 1990. Also, in 2000, the publications had appeared in a wider range of journals and showed a growth trend in the numbers employing qualitative methods in contrast to quantitative or mixed methods. Despite this, the percentage of publications that was data-based as distinguished from discussion-focused remained at 30% in the two time periods. Finally, the most common themes emerging from the review that were perceived to be shaping the direction of the emergent field were identified: (1) providing a broad and general understanding of occupation, (2) nurturing occupational therapy by providing it with a science-based foundation, (3) seeing occupational science as a vehicle for defending occupational therapy's commitment to certain values or ideals, and (4) describing the discipline as one that achieves social reform by championing occupation's place in social justice, a theme that was seen largely in the latter set of publications and in those written by Canadian and Australian authors.

The second study, which has just been completed by Glover (2007), builds on the preceding one by examining many more years to gain a finer-grained picture of publication trends. To be included in the study, the publication had to have appeared in a journal in any of the years between 1996 and 2006. As in the first study, the publication had to use the term *occupational science* or *science of occupation* in its title, key words, or abstract. However, in this study, only articles that appeared in peer-reviewed journals were included because these are considered by the scientific community to be the most legitimate vehicle for disseminating new findings. The selection process resulted in the identification of 244 articles. When publi-

cations from the earlier years were compared to those in later years, Glover found that although publication numbers fluctuated from year to year, in general, more articles were published in more recent years. Furthermore, over time the proportion of data-based articles increased, most being qualitative in nature. Also, the majority of publications addressed adults 18 to 64 years of age and without disability, although a hefty 26.8% did concern people with disabling conditions, a larger representation than would typically be found in traditional social sciences (such as anthropology or geography). Authors tended to be from the United States, Canada, and Australia, although other countries were also represented. Finally, in later years, a greater proportion of articles indicated that the work reported had been supported by extramural funding. This trend is particularly important because the prestige and growth of an academic discipline are largely contingent on receiving grants from federal and other agencies. In summary, although these two studies represent only a first cut in assessing how occupational science publications are developing, they nevertheless suggest that the discipline has grown impressively as it enters its third decade.

LINKAGES BETWEEN OCCUPATIONAL SCIENCE AND OCCUPATIONAL THERAPY

In 2017, the profession of occupational therapy will be 100 years old. In anticipation of this landmark occasion, the American Occupational Therapy Association (AOTA) has adopted the following Centennial Vision:

> By the year 2017, we envision that occupational therapy is a powerful, widely recognized, science-driven, and evidence-based profession with a globally connected and diverse workforce meeting society's occupational needs. (AOTA, 2007, paragraph 1)

How does occupational science relate to this vision? Or, to back up a bit, what is the relationship between occupational science and occupational therapy? We will make the case that the relationship between occupational science and occupational therapy is symbiotic, that each contributes to the survival of the other (Clark, 2006), and that occupational science is the vehicle through which the profession is becoming more science-driven and evidence-based.

The founders of occupational science, as we have explained, originally conceived of the discipline as basic in nature but as existing, in part, to nurture occupational therapy (Clark et al., 1991; Wilcock, 1991; Yerxa, 1993; Yerxa et al., 1989). Designating the science as basic at the time made sense for two reasons: First, the founders saw the advantage of building theory on occupation (basic science), in the general sense, without concern for its specific application in therapy (applied science). At that time, no

discipline had occupation as its core subject matter, and it was clear that a science devoted to the study of occupation could have benefits that went well beyond occupational therapy practice. For example, this discipline could contribute new knowledge on occupation and synthesize existing interdisciplinary knowledge for use by those who are interested in preventing chronic illness and disability, promoting global health, or simply expanding our understanding of this central feature of human existence. The second reason was more practical. Universities in the decade of the 1980s privileged basic science over applied science. The climate was such that the chances of being able to establish a new basic science rather than an applied one were better. However, it should be reiterated that in the founders' original conceptualization, occupational science was always intended to furnish knowledge that could be used to theoretically inform, and thereby refine and develop, occupational therapy interventions.

Although a debate initially took place on whether or not occupational science should be independent of occupational therapy (Carlson & Dunlea, 1995; Clark, 1993; Clark et al., 1993; Lunt, 1997; Mosey, 1992, 1993), the two have subsequently become closely interlinked. Much attention has been placed on the relationship between occupational therapy and occupational science in the beginning, a kind of creation story, in which occupational science is purported to have grown out of occupational therapy. Lunt (1997) somewhat provocatively proposed that occupational science might have been created as a vehicle for elevating status of the study of occupation and distancing the field from the "dirty work" of a practicing field such as occupational therapy, a perspective that we and others would dispute.

In fact, the ties between occupational science and occupational therapy were reinforced in 1997 (nine years after the founding of the discipline) when Zemke and Clark (1996a, 1996b) moved away from defining occupational science as a basic science, recommending that its focus be not only on the nature of occupation, but also on how it is used in occupational therapy contexts. The fruitful ways in which occupational science has contributed to the profession of occupational therapy and to the addressing of societal needs have increased the excitement surrounding the discipline and the sense of its worthiness (Carlson & Dunlea, 1995; Clark, 1993; Jackson, Carlson, Mandel, Zemke, & Clark, 1998). Generation of knowledge for occupational therapy is frequently described as the primary aim or purpose for the discipline, and the need for more theory about occupation within occupational therapy curricula has also been noted (Whiteford & Wilcock, 2001; Yerxa, 1993). Interest in the study of occupation as related to the practice of occupational therapy has surged in recent years, and many people in the field consider it to be part of a kind of course correction to return current practice to its philosophical roots, overcoming the reductionism that marked the tight coupling of the field with biomedicine, particularly around the 1970s (e.g., Wilcock, 2001).

Basic research on the nature of occupation, including its observable and phenomenological aspects, can be catalytic for improving existing therapeutic approaches and creating new ones, moving the profession away from reliance on "adhoc, recipe-based knowledge" (Abbott, 2004, p. 4). Similarly, studies on the impact of occupation on the health of individuals, communities, and the global arena can result in an expansion in occupational therapy's scope of practice. In addressing a wide variety of topics that are relevant to the general population, occupational science can broaden occupational therapy's professional jurisdiction while appropriating the profession greater stature and credibility. For example, as scientific evidence is produced that demonstrates the ways in which health-promoting activity lessens the risk for developing chronic diseases or disability, occupational therapy will become better positioned to stake a claim in the prevention arena. Just as much of dental practice (since the discovery of fluoride) is dedicated to prevention, so too could a significant amount of occupational therapy practice be aimed at preventing the very diseases and disabilities that its practitioners have traditionally remediated. In this way, the profession will be able to stake out new territory for its therapeutic work (Abbott, 2004). Finally, the applied arm of occupational science can produce the much-needed outcome studies on intervention effectiveness. This broader conceptualization of occupational science, that is, as a comprehensive translational science, is the way in which the discipline is now taking shape in the United States, a development that provides a goodness-of-fit with what is required for realization of AOTA's Centennial Vision.

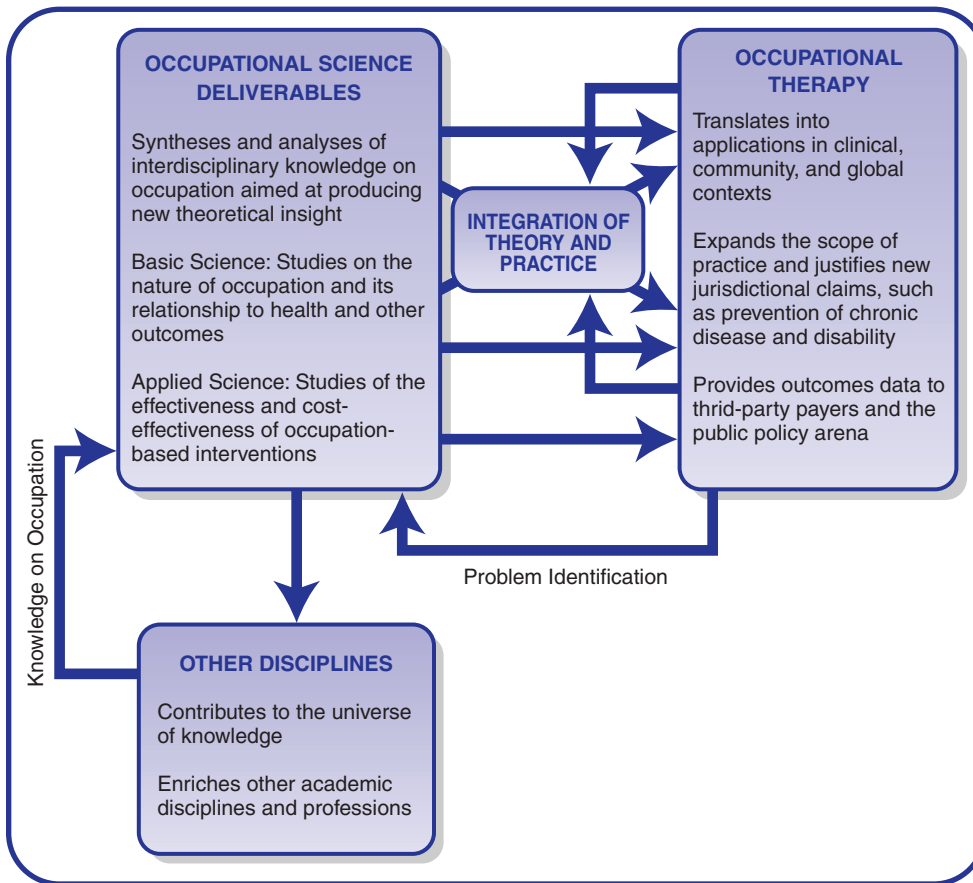
Figure 1.1 depicts graphically the ways in which occupational science is related to other disciplines as well as to occupational therapy, its primary practice arm. In this model, occupational science is seen as contributing its subject matter and research findings to the universe of knowledge. In doing so, it enriches other academic disciplines and professions, simultaneously creating widespread understanding of its focus. Reciprocally, these fields supply intellectual content and research findings that are of relevance to occupation back to occupational science. Occupational science is also shown as being highly intermeshed with occupational therapy. The various kinds of knowledge that are generated by the field, overall, are seen as bolstering the scientific credibility of the profession and could lead to increased growth in third-party payment for occupational therapy services and the enactment of public policies that render occupational therapy services more widely available. Syntheses of interdisciplinary knowledge and basic science on occupation can be translated into innovative treatment advances or used to refine existing protocols. They can also provide justification for expanding professional jurisdictional claims (Abbott, 2004).


FIGURE 1.1 Interlinks between occupational science, occupational therapy, and other academic disciplines and fields: a mechanism for furthering the Centennial Vision.

As can be seen in Figure 1.2, we believe that the confluence of these activities will lead to greater public awareness and valuing of the occupational therapy profession, ultimately generating benefits to society. However, for occupational science and occupational therapy to be intermeshed in this way and to further key aspects of the Centennial Vision, a carefully thought-out division of labor is required. In Figure 1.3, a diverse occupational therapy/occupational science workforce (including scientists, educators, and practitioners) is depicted. Practitioners (occupational therapy assistants and occupational therapists) are depicted as working across diverse settings, where they will implement traditional and new models of practice for individuals, groups, and communities. They may also be invited to share their up-to-date clinical expertise in educational programs or become interventionists on clinical trial research teams. Occupational scientists with PhD or ScD degrees are seen as constituting the core tenure-track faculty and the main cadre of researchers developing the body of occupational science knowledge, doing large-scale outcome studies, and infusing findings in curricula. Practitioners and faculty who have Doctor of Occupational Therapy (OTD) degrees are pictured as being in the lead position for drawing from occupational science to develop intervention models and study their effectiveness, as well as for joining faculty who have PhDs in updating curricula in accord

with new scientific breakthroughs. We conceive of this new breed of OTDs as pioneer experts in clinical practice and as leaders in facilitating education, policy, or administrative changes to create alignments with the Centennial Vision.

AN ILLUSTRATION OF THE RESEARCH PROCESS: THE USC WELL ELDERLY STUDY

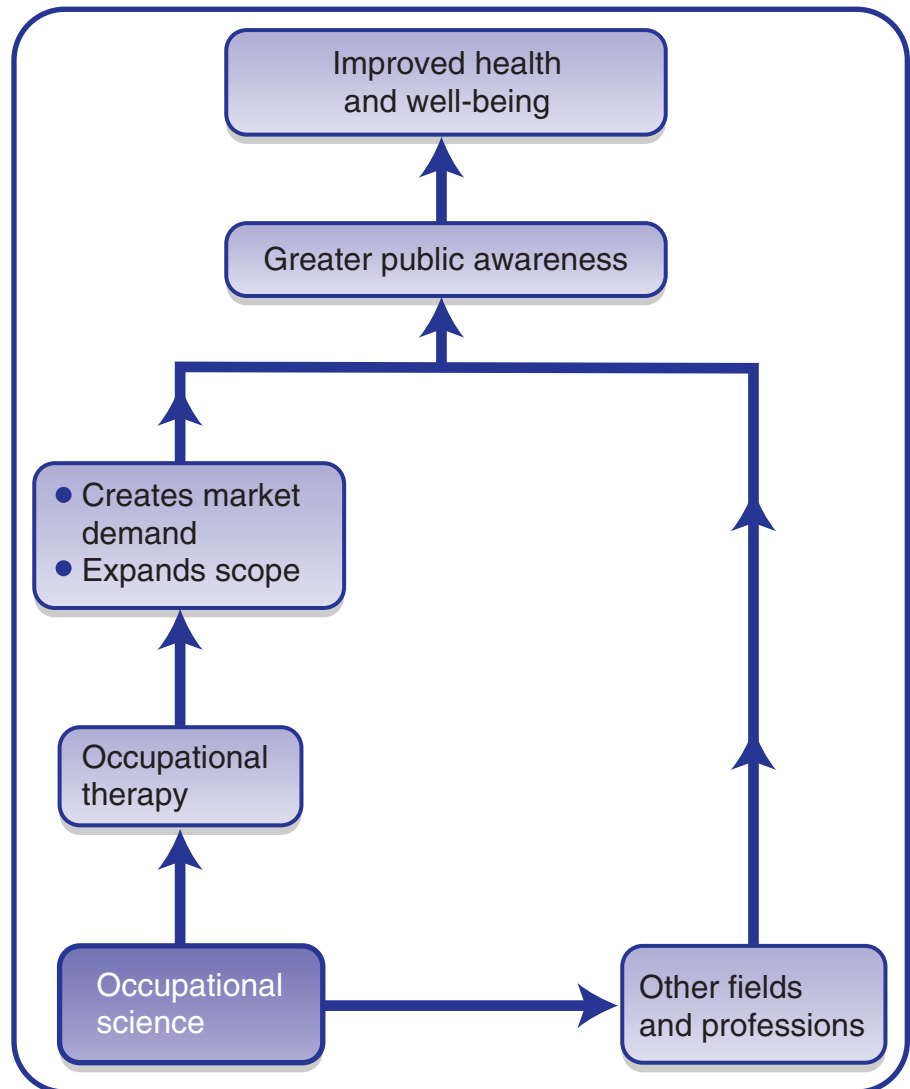
To explicate one way in which occupational science has nurtured occupational therapy, we will now describe a template for conducting translational research that is used by the USC Well Elderly Study group (Clark et al., 1997; Clark, Azen et al., 2001; Hay et al., 2002; Jackson et al., 1998; Mandel, Jackson, Zemke, Nelson, & Clark, 1999). A research team that has been funded through federal grant support. The trajectory of research activities as designed by this team is depicted in Figure 1.4. The research program begins by identifying a problem worthy of investigation (Step 1). For example, in the USC Well Elderly Study, the problem was framed as whether or not an activity (occupation) based intervention could slow down the declines that are normally associated with aging or improve health in the elderly (Clark et al., 1997; Mandel et al., 1999). The group used qualitative research meth-


FIGURE 1.2 Overview of linkages that can support public awareness of occupational therapy.

ods to obtain a detailed and complex understanding of the contextual factors that needed to be taken into consideration (Step 2) (Mandel et al., 1999). Following this qualitative work, which can be thought of as more basic than applied science, the findings were then used to enhance aspects of occupational therapy practice, by refining existing approaches or creating new interventions (Step 3) (Mandel et al., 1999).

The research group sought federal funding to conduct a large-scale clinical trial (Step 4) that employs quantitative methods to demonstrate the cost-effectiveness (Step 5) of the new or refined therapeutic approach (applied science). If the results of the trial demonstrate effectiveness, the next step is to obtain funding to conduct subsequent studies on the mechanisms that account for the positive outcomes (Step 6). This work, in turn, can lead to further theory development and practice improvements (Step 7). The process, which initially might have seemed disconnected from practice, culminates in therapeutic innovation and the delivery of outcomes data that can have a

positive effect on reimbursement for services and public policy decisions. Ultimately, the Well Elderly Study demonstrated the cost-effectiveness of a preventive occupational therapy program, entitled Lifestyle Redesign®, in improving health outcomes in the elderly (Clark et al., 1997; Clark, Azen, et al., 2001; Hay et al., 2002).

REFRAMING OCCUPATIONAL SCIENCE AND BIOMEDICAL CONDITIONS THROUGH THE USC/RANCHO LOS AMIGOS NATIONAL REHABILITATION CENTER PRESSURE ULCER PREVENTION STUDY

One commonly held misconception is that occupational science is too "soft" a discipline to create substantive innovation in the treatment of biomedical conditions. This line

of thinking assumes that contextual factors and other complex life circumstances are not particularly relevant to the care of patients who have, or are at risk for, discrete biologically based impairments, diseases, or disabilities. It also is grounded in the preconception that a discipline that is focused on explaining occupation and its impact on health is too removed in its emphases from traditional biomedical procedures and practices to have genuine payoffs in the provision of care. We will try to illustrate that such circumscribed reasoning is limiting and problematic. To accomplish this, we will describe the methods that are used as well as the findings and resources that have been generated through the USC/Rancho Los Amigos National Rehabilitation Center Pressure Ulcer Prevention Study (PUPS) study (Clark et al., 2006). Not only has this research program resulted in innovations in occupational therapy treatment in the area of pressure ulcer prevention, but it has also generated resource materials (USC/RLRPUPP, 2006a, 2006b, 2006c) that are intended to improve best practices for the wider community of rehabilitation professionals.

The PUPS study team selected the problem of pressure ulcer prevention in people with spinal cord injury to work on for three reasons (Step 1 in Figure 1.4). First, the general area of pressure ulcer prevention had been identified as a significant national health concern. For example, both Healthy People 2010 and the Joint Commission on Accreditation of Health Care Organizations identified it as a key priority (Martucci, 2006). Second, existing best practices have failed to address the problem adequately with the costs of wound management soaring. Once pressure ulcers are at advanced stages, the cost of care is astronomical with surgical costs reaching as much as $70,000 per wound (Clark et al., 2006). Having the expertise to do

cost-effectiveness studies, the PUPS research team was attracted to this research area in part because of the potential through scientific discovery to reduce the burden of these health care costs. However, finally, and perhaps most importantly, a literature review had revealed that recurrent pressure ulcers were serious threats to the quality of life of people with spinal cord injuries, compromising their potential to express themselves as occupational beings (Clark et al., 2006; Clark, Sanders, Carlson, Jackson, & Imperatore-Blanche, in press; Consortium for Spinal Cord Medicine, 2000; Cutajar & Roberts, 2005). Typically, the occurrence of an advanced pressure ulcer requires months of confinement to bed, creates a decrease in functional ability because of muscle loss due to surgery, and can cause depression and an overwhelming sense of helplessness. The PUPS team therefore decided to use a full-fledged occupational science–based strategy incorporating the steps in the translational research template shown in Figure 1.4 for investigating this seemingly intractable problem, which manifests itself proximally as skin breakdown, a discrete biomedical condition, but then has radiating distal effects on both private lives and the public reimbursement sector.

In executing the second step of the translational research template (see Figure 1.4), the PUPS team secured a Field Initiated Research Grant (#H133G000062) from the National Institute of Disability and Rehabilitation Research to conduct a qualitative study to obtain new and detailed understandings of the complex interplay of life circumstances and other contextual factors that contribute to the development of pressure ulcers in people with spinal cord injury. The methodology entailed conducting in-depth interviews and participant observation of events that led to pressure ulcer development in the lives of 19 people with

Step 1. Identify problems *(e.g., can an activity [occupation] based intervention slow down the declines normally associated with aging?)*

Step 2. Develop theoretical understanding of problems—Identification of intervention needs and domains of concerns *(e.g., mobility maintenance, personal safety)*

Step 3. Develop intervention *(e.g., Lifestyle Redesign®)*

Step 4. Test intervention outcomes (randomized clinical trial)
Short term

Step 5. Evaluate cost-effectiveness

Step 6. Study theoretical model for why outcomes were produced—Basic qualitative or quantitative research *(e.g., intervention leads to healthy activity, which leads to increased health and well-being)*

Step 7. Theory development

Outcome: Theoretically informed intervention improvement

Outcome: New knowledge on occupation and health

FIGURE 1.4   Blueprint for a translational science research program.

spinal cord injury and one person with spinal myelitis, all of whom had had a history of recurrent pressure ulcer development. The findings underscored the significant degree to which a complex cluster of factors led to the emergence of pressure ulcers (Clark et al., 2006). Results revealed several principles that addressed the complexity of contextual concerns that tended to explain pressure ulcer development in people with spinal cord injury (USC/RLRPUPP, 2006c). They also led to the creation of a set of models that described the daily lifestyle factors that influenced the likelihood of incurring a pressure ulcer (Clark et al., 2006). From the findings, it was clear that focusing on convention-

ally linked factors such as equipment breakdowns or failure to comply with the pressure relief procedures was insufficient in explaining how the participants developed pressure ulcers. Factors related to occupation, such as moment-to-moment decision making on whether or not to engage in a high-risk activity, negotiating tradeoffs between pursuing a passion and resting when an ulcer was in an early stage, or problem solving in unanticipated and unusual circumstances such as being trapped in an airport for 16 hours, were often pivotal in contributing to pressure ulcer development. To date, this research program has demonstrated that prevention efforts need to take into account the unique

constellations of circumstances in a person's everyday life (Clark et al., 2006), that traditional assessments of pressure ulcer risk need to be broadened to include factors related to life situations (Seip, Carlson, Jackson, & Clark, 2007), and that more attention needs to be given to the decisions people make about their daily activity engagement when a pressure ulcer is in an early stage, to minimize the likelihood that it will advance to a stage for which surgery is required (Dunn, Carlson, Jackson, & Clark, 2007).

While the thrust of the PUPS study described above leans on the side of being basic in nature, in that the primary goal of the initial study was descriptive, the research team has translated the findings into applications that might turn out not only to expand occupational therapy's stake in the area of wound prevention and care, but also to yield practical benefits for other rehabilitation professionals, and real-life, real-world benefits to people who are prone to pressure ulcer development. First, the PUPS team used the findings to develop an innovative Lifestyle Redesign® Pressure Ulcer Prevention Program (USC/RLRPUPP, 2006a) that was intended for use by occupational therapists. Second, it produced a Rehabilitation Professionals Manual and a Companion Manual, which exist in hard copy and CD-ROM formats, that were intended as a resource for all rehabilitation professionals working in this area (USC/RLRPUPP, 2006c). These manuals contain narratives of the life circumstances that led to the development of pressure ulcers in the 20 study participants. The format is interactive, containing elements such as decision trees, questions addressing various dilemmas related to pressure ulcer risk with a choice of several possible solutions of varying degrees of correctness, and highlighted words embedded in the stories that represent factors that place particular participants at risk for pressure ulcer development. Clicking on the highlighted text in the Rehabilitation Professionals Manual takes the reader to a corresponding article in the Companion Manual that summarizes recent research on the topic of interest. Finally, the PUPS team drew from the findings to create a manual for consumer use, which can be easily accessed at http://www.pressureulcerprevention.com and contains articles on 46 factors that were found to contribute to the development of pressure ulcers in the actual lives of the study participants.

At this point, with a manual of interventions in hand that incorporates traditional occupational therapy approaches to pressure ulcer prevention with new strategies derived from the PUPS study, the research team is now attempting to secure federal funding to conduct a large-scale randomized clinical trial with hopes of demonstrating the intervention's cost-effectiveness. Members of the team also intend to develop an assessment based on the findings that will be capable of predicting risk with more exactitude than is typical of currently used pressure ulcer risk assessments. Assuming that they are successful, the PUPS study will be able to demonstrate the way in which occupational science supports the development of state-of-the-art rehabilitation interventions, contributes to a complex understanding of pressure ulcer risk, translates into concrete occupational therapy approaches, and provides consumer access to new information on the factors that lead to the development of pressure ulcers.

CONCLUSION

The PUPS study has the potential to illustrate how a detailed understanding of daily lives and occupations, acquired through science, can lead to strong, multifaceted theoretically informed intervention approaches that go well beyond traditional biomedical protocols. In this way, occupational science can fortify occupational therapy. In turn, occupational therapy, strengthened by occupational science, will be better positioned for securing new reimbursement streams and expanding its scope. As occupational therapy becomes recognized as a scientifically driven and evidence-based practice, its clinicians will go on to identify the next problem areas that need to be tackled by occupational scientists.

PROVOCATIVE QUESTIONS

1. How is the described relationship between occupational science and occupational therapy mutually beneficial?
2. What do you think are the most pressing problems to address through the proposed translational science research program?
3. In your mind, jump ahead 10 years. Envision yourself to be writing a section describing recent developments in occupational science over the past decade. What might you be able to say or hope to be able to say?

ON THE WEB

What Is Occupation?

VIRGINIA DICKIE

> **Mr. Jourdain.** You mean to say that when I say "Nicole, fetch me my slippers" or "Give me my nightcap" that's prose? **Philosopher.** Certainly, sir. **Mr. Jourdain.** Well, my goodness! Here I've been talking prose for forty years and never known it . . .
>
> —Moliere (1670)

Learning Objectives

After reading this chapter, you will be able to:

1. Identify and evaluate ways of knowing occupation.
2. Articulate different ways of defining and classifying occupation.
3. Describe the relationship between occupation and context.

KNOWING AND LEARNING ABOUT OCCUPATION

Reading the paper, washing hands, throwing a Frisbee, walking through a colorful market in a foreign country, telling a story (in poetry or prose)—all are occupations people do without ever thinking about them as being occupations. Many occupations are ordinary and become part of the context of daily living. Such occupations are generally taken for granted and most often are habitual (Aarts & Dijksterhuis, 2000; Bargh & Chartrand, 1999; Wood, Quinn, & Kashy, 2002). In the myriad of activities people do every day, they do *occupation* all their lives, perhaps without ever knowing it.

Occupations are ordinary, but they can also be special when they represent a new achievement such as driving a car or when they are part of celebrations and rites of passage. Preparing and hosting Thanksgiving dinner for the first time and baking the pies for the annual family holiday for the twentieth time are examples of special occupations. Occupations tend to be special when they happen infrequently and carry symbolic meanings such as representing achievement of adulthood or one's love for family. Occupations are also special when they form part of a treasured routine such as reading a bedtime story to one's child, singing "Twinkle, Twinkle, Little Star," and tucking the covers around the small, sleepy body. But even special

occupations, while heavy with tradition, may change over time. Hocking, Wright-St. Clair, and Bunrayong (2002) illustrated the complexity of traditional occupations in their study of holiday food preparation by older women in Thailand and New Zealand. The study identified many similarities between the groups (such as the activities the authors named "recipe work"), but the Thai women valued maintenance of an invariant tradition in what they prepared and how they did it, while the New Zealand women changed the foods they prepared over time and expected such changes to continue. Nevertheless, the doing of food-centered occupations around holidays was a tradition for both groups.

To be human is to be occupational. Occupation is a biological imperative, evident in the evolutionary history of humankind, the current behaviors of our primate relatives, and the survival needs that must be met through occupation (Clark, 1997; Krishnagiri, 2000; Wilcock, 1998; Wood, 1998). Fromm (as cited by Reilly, 1962), asserted that people had a "physiologically conditioned need" to work as an act of self-preservation (p. 4). Humans also have occupational needs beyond survival. Addressing one type of occupation, Dissanayake (1992, 1995) argued that making art, or, as she describes it, "making special," is a biological necessity of human existence. According to Molineux (2004), occupational therapists now understand humans, their function, and their therapeutic needs in an occupational manner in which *occupation is life itself* [emphasis added]. Townsend (1997) described occupation as the "active process of living: from the beginning to the end of life, our occupations are all the active processes of looking after ourselves and others, enjoying life, and being socially and economically productive over the lifespan and in various contexts" (p. 19).

THE NEED TO UNDERSTAND OCCUPATION

Occupational therapy practitioners need to base their work on a thorough understanding of occupation and its role in health. Understanding occupation is more than having an easy definition (which is a daunting challenge in its own right). To know what occupation is, it is necessary to examine what humans do with their time, how such activities are organized, what purposes they serve, and what they mean for individuals and society.

Personal experience of doing occupation, whether consciously attended to or not, provides a fundamental understanding of occupation—what it is, how it happens, what it means, what is good about it, and what is not. This way of knowing is both basic and extraordinarily rich.

Looking Inward to Know Occupation

If you had asked me about gardening when I was young, I would have described the hard work of weeding the family garden on hot summer days, emphasizing that gardening was a *chore.* In my parents' garden I learned a great deal about how to garden, such as varieties of flowers and vegetables, sunshine and rain requirements, weed identification, and how to grasp a weed to pull it out with all its roots. This is *knowledge* of rules and techniques, of how to *do* gardening. Now, many years later, I know gardening in a very different way. Weeding is one of my great pleasures. I understand the challenges of learning to garden in new places, the patience required to discover what will grow where, and the right time of year to plant. Between my youth and the present, gardening has taken on a different *form* (no longer a chore assigned by my parents but now creating and maintaining a low-tillage series of small gardens with herbs, shrubs, flowers, and selected vegetables on my own initiative or with my husband), *function* (then I gardened to avoid displeasing my parents, and now I garden to meet my own needs for aesthetic pleasures and satisfying "doing"), and *meaning* (from being a neutral to disagreeable series of chores to being a source of relaxation, reflection, shared time, and gratifying hard work). These elements—the form, function, and meaning of occupation—are the basic areas of focus for the science of occupation (Larson, Wood, & Clark, 2003).

To be useful to occupational therapy practitioners, knowledge of occupation based on personal experience demands examination and reflection. What do we do, how do we do it, when and where does it take place, and what does it mean? Who else is involved directly and indirectly? What capacities does it require in us? What does it cost? Is it challenging or easy? How has this occupation changed over time? What would it be like if we no longer had this occupation? My gardening example illustrates how occupation is a *transaction* with the *environment* or *context* of other people, plants, earth, and weather. It includes the *temporal* nature of occupation—seasonal variations but also change over time and perhaps some notion of occupation filling time. That I call myself a gardener exemplifies how occupation has become part of my *identity* and suggests that it might be difficult for me to give up gardening.

Basic as it is, however, understanding derived from personal experience is insufficient as the basis for practice. Reliance solely on this source of knowledge has the risk of expecting everyone to experience occupation in the same manner as the therapist. So while occupational therapy practitioners will profit in being attuned to their own occupations, they must also turn their view to the occupation around them and to understanding occupation through study and research.

Looking Outward to Know Occupation

Observation of the world through an occupational lens is another rich source of occupational knowledge. Connoisseurs of occupation can train themselves to new ways of seeing a world rich with occupations: the way a restaurant hostess manages a crowd when the wait for seating is long, the economy of movement of a construction worker

ing of occupation drawn from research in occupational therapy and occupational science as well as other disciplines. Hocking (2000) developed a framework of needed knowledge for research in occupation, organized into the categories of the "essential elements of occupation . . . occupational processes . . . [and the] relationship of occupation to other phenomena" (p.59). This research is being done within occupational therapy and occupational science, but there is also a wealth of information to be found in the work of other disciplines. For example, in anthropology, Orr studied the work of copy machine repairmen (1996), and Downey (1998) studied computer engineers and what they did. Consumer researchers have studied Christmas shopping (Sherry & McGrath, 1989), motorcycle riding (Schouten & McAlexander, 1995), and many other occupations of consumption. Psychologists have studied habits (Aarts & Dijksterhuis, 2000; Bargh & Chartrand, 1999; Wood, Quinn, & Kashy, 2002) and a wealth of other topics that relate to how people engage in occupation. Understanding of occupation will benefit from more research within occupational therapy and occupational science and from accessing relevant works of scholars in other fields.

DEFINING OCCUPATION

For many years, the word *occupation* was not part of the daily language of occupational therapists; nor was it prominent in the profession's literature (Hinojosa, Kramer, Royeen, & Luebben, 2003). According to Kielhofner and Burke (1977), the founding paradigm of occupational therapy was occupation, and the occupational perspective focused on people and their health "in the context of the culture of daily living and its activities" (p. 688). But beginning in the 1930s, occupational therapy strove to become more like the medical profession, entering into a paradigm of **reductionism** that lasted into the 1970s with occupation, both as a concept and as a means and/or outcome of intervention, essentially absent. With time, a few professional leaders began to call for occupational therapy to return to its roots in occupation (Schwartz, 2003), and since the 1970s, acceptance of occupation as the foundation of occupational therapy has grown (Kielhofner, 1997). With that growth, professional debates about the definition and nature of occupation emerged, and they continue to this day.

Defining occupation in occupational therapy is challenging because the word is part of common language with meanings that the profession cannot control. The term *occupation* and related concepts such as *activity, task, employment,* and *work* are used in many ways within occupational therapy. It seems quite logical to think of a job, or cleaning house, or bike riding as an occupation, but the concept is fuzzier when we think about the smaller components of these larger categories. Is dusting an occupation, or is it part of the occupation of house cleaning? Is riding a bike a skill that is part of some larger occupation,

FIGURE 2.1   What occupations are represented in this picture?

doing a repetitive task, the activities of musicians in the orchestra pit when they are not playing. People like to talk about what they do, and the student of occupation can learn a great deal by asking for information about people's work and play. By being observant and asking questions, people increase their repertoires of occupational knowledge far beyond the boundaries of personal interests, practices, and capabilities (Figure 2.1).

Observation of others' occupations enriches the occupational therapy practitioner's knowledge of the range of occupational possibilities and of human responses to occupational opportunities. But while this sort of knowledge goes far beyond the limits of personal experience, it is still bounded by the world any one person is able to access, and it lacks the depth of knowledge that is developed through research and scholarship.

Turning to Research and Scholarship to Understand Occupation

Knowledge of occupation that comes from personal experience and observation must be augmented with understand-

such as physical conditioning or getting from home to school, or is it an occupation in its own right? Does this change over time?

The founders of occupational therapy used the word *occupation* to describe a way of "properly" using time that included work and worklike activities and recreational activities (Meyer, 1922/1977). Breines (1995) pointed out that the founders chose a term that was both ambiguous and comprehensive to name the profession, and she argued that this choice was not accidental. The term was open to holistic interpretations that supported the diverse areas of practice of the time, encompassing the elements of occupation defined by Breines (1995) as "mind, body, time, space, and others" (p. 459). The term *occupation* spawned ongoing examination, controversy, and redefinition as the profession has matured.

Nelson (1988, 1997) introduced the terms *occupational form,* "the preexisting structure that elicits, guides, or structures subsequent human performance," and *occupational performance,* "the human actions taken in response to an occupational form" (1988, p. 633). This distinction separates individuals and their actual doing of occupations from the general notion of an occupation and what it requires of anyone who does it.

Yerxa et al. (1989) defined occupation as "specific 'chunks' of activity within the ongoing stream of human behavior which are named in the lexicon of the culture. . . . These daily pursuits are self-initiated, goal-directed (purposeful), and socially sanctioned" (p. 5). Yerxa (1993) further elaborated this definition to incorporate an environmental perspective and a greater breadth of characteristics. "Occupations are units of activity which are classified and named by the culture according to the purposes they serve in enabling people to meet environmental challenges successfully. . . . Some essential characteristics of occupation are that it is self-initiated, goal directed (even if the goal is fun or pleasure), experiential as well as behavioral, socially valued or recognized, constituted of adaptive skills or repertoires, organized, essential to the quality of life experienced, and possesses the capacity to influence health" (p. 5).

According to the Canadian Association of Occupational Therapists (as cited in Law, Steinwender, & Leclair, 1998), occupation is "groups of activities and tasks of everyday life, named, organized and given value and meaning by individuals and a culture. Occupation is everything people do to occupy themselves, including looking after themselves (self-care), enjoying life (leisure), and contributing to the social and economic fabric of their communities (productivity)" (p. 83). More recently, occupational scientists Larson, Wood, and Clark (2003) provided a simple definition of occupation as "the activities that comprise our life experience and can be named in the culture" (p. 16).

The previous definitions of occupation from occupational therapy literature help in explaining why occupation is the profession's focus (particularly in the context of therapy), yet they are open enough to allow continuing research on the nature of occupation. Despite, and perhaps because of, the ubiquity of occupation in human life, there is still much to learn about the nature of occupation through systematic research using an array of methodologies (Hocking, 2000; Molke, Laliberte-Rudman, & Polatajko, 2004). Such research should include examination of the premises that are built into the accepted definitions of occupation.

CONTEXT AND OCCUPATION

The photograph of the two young boys playing in the garden sprinkler evokes a sense of a hot summer day and the experience of icy cold water coming out of the sprinkler, striking and stinging the boys' faces and tongues (Figure 2.2). Playing in the sprinkler has a context with temporal elements (summer, the play of children, and the viewer's memories of doing it in the past), a physical environment (grass, hot weather, hose, sprinkler, cold water), and a social environment (a pair of children and the likelihood of an indulgent parent). Playing in the sprinkler cannot be described or understood—or even happen—without its context. It is difficult to imagine that either boy would enjoy the activity as much doing it alone; the social context is part of the experience. A sprinkler might be set up for play on an asphalt driveway but not in a living room. Parents would be unlikely to allow their children to get soaking wet in cold weather. The contexts of the people viewing the picture are important too; many will relate the picture to their own past experiences, but someone who lives in a place where lawn sprinklers are never used might find the picture meaningless and/or confusing. This example illustrates how occupation and context are enmeshed with one another.

It is generally accepted that the specific *meaning* of an occupation is fully known only to the individual engaged

FIGURE 2.2   Two boys on a hot summer day.

in the occupation (Larson, Wood, & Clark, 2003; Pierce, 2001; Weinblatt, Ziv, & Avrech-Bar, 2000). But it is also well accepted that occupations take place in *context* (sometimes referred to as the environment) (e.g., Baum & Christiansen, 2005; Kielhofner, 2002; Law, Cooper et al., 1996; Schkade & Schultz, 2003; Yerxa et al., 1989) and thus have dimensions that consider other humans (in both social and cultural ways), temporality, the physical environment, and even virtual environments (American Occupational Therapy Association, 2002).

Description of occupation as taking place *in* or *with* the environment or context implies a separation of person and context that is problematic. In reality, person, occupation, and context are inseparable. Context is changeable but always present. Cutchin (2004) offered a critique of occupational therapy theories of adaptation-to-environment that separate person from environment, and proposed that John Dewey's view of human experience as "always situated and contextualized" (p. 305) was a more useful perspective. According to Cutchin, "situations are always inclusive of us, and us of them" (p. 305). Occupation occurs at the level of the situation and thus is inclusive of the individual and context (Dickie, Cutchin, & Humphry, 2006). Occupational therapy interventions cannot be context free. Even when an occupational therapy practitioner is working with individuals, the contexts of other people, the culture of therapist and client, the physical space, and past experiences are present.

IS OCCUPATION ALWAYS GOOD?

In occupational therapy, occupation is associated with health and well-being, both as a means and as an end. But occupation can also be unhealthy, dangerous, maladaptive, or destructive to self or others and can contribute to societal problems and environmental degradation. For example, the seemingly benign act of using a car to get to work, run errands, and pursue other occupations can limit one's physical activity and risk injury to self and others. Furthermore, Americans' reliance on the automobile contributes to urban sprawl, the decline of neighborhoods, air pollution, and over use of nonrenewable natural resources.

Personal and societal occupational choices have consequences, good and bad. In coming to understand occupation, we need to acknowledge the breadth of occupational choices and their effects on individuals and the world itself.

ORGANIZING OCCUPATION

Categorization of occupations (for example, into areas of activities of daily living, work, and leisure) is often problematic. Attempts to define work and leisure demonstrate that distinctions between the two are not always

FIGURE 2.3   A complex social occupation.

clear (Csikszentmihalyi & LeFevre, 1989; Primeau, 1996). Work may be defined as something people *have* to do, an unpleasant necessity of life, but many people enjoy their work and describe it as "fun." Indeed, Hochschild (1997) discovered that employees in the work setting she studied often preferred the homelike qualities of work to being in their actual homes and consequently spent more time at work than was necessary. The concept of leisure is problematic as well. Leisure might involve activities that are experienced as hard work, such as helping a friend to build a deck on a weekend.

Similar problems can be described with any categorization scheme. The photograph of the women around a table illustrates the difficulty in applying categories to a real situation (Figure 2.3). Some individuals are eating, so perhaps they are engaged in an activity of daily living. Others are talking or listening, so their occupation might be social participation. The tables pushed together and the folder and pen suggest that the meal might be a meeting of some sort, so perhaps this eating is work. Notice the hand positions of the women eating; the European style of eating with fork in left hand and knife in right used by some (but not all) could be a clue that this meal involves international travel. Does this make it a leisure occupation? No simple designation of what is happening in the picture will suffice.

Another problem with categories is that an individual may experience an occupation as something entirely different from what it appears to be to others. Weinblatt, Ziv, & Avrech-Bar (2000) described how an elderly woman used the supermarket for purposes quite different from provisioning (which would likely be called an instrumental activity of daily living). Instead, this woman used her time in the store as a source of new knowledge and interesting information about modern life. What should we call her occupation in this instance?

The construct of occupation might very well defy efforts to reduce it to a single definition or a set of categories.

Just as the photograph of the women eating illustrates the pitfalls of trying to fit occupations into a single category, examples of occupations can be found that challenge other theoretical approaches and definitions. Nevertheless, the richness and complexity of occupation will continue to challenge occupational therapists to know and value it through personal experience, observations, and scholarly work. The practice of occupational therapy depends on this knowledge.

PROVOCATIVE QUESTIONS

1. Why should a national health care system (however that system is organized) be concerned about occupation and support occupational therapy services? Construct an argument that focuses on occupation.

2. Is it of major importance for the profession of occupational therapy to use a single definition of occupation? Defend your answer.

Occupation and Development: A Contextual Perspective

3

RUTH HUMPHRY

Learning Objectives

After reading this chapter, you will be able to:

1. Reflectively explore the origins and nature of your own knowledge about children, development, and what children of certain ages like to do.
2. Explain the societal nature of everyday activities of children and culture made for children.
3. Engage in analysis of children's interpersonal interactions during a shared occupation and describe the forces that influence the acquisition of and transformation in occupations.
4. Describe how children's experiences of meaning and purpose shape occupational engagement and serve as change mechanisms.
5. Recognize the complex transactions of children with their environments as functional systems.

INTRODUCTION AND DEFINITIONS

As you have learned, the construct of *occupation* has defied definition and categorization (see Chapter 2). This applies as well to children's occupations. The general idea that occupations are the everyday activities and special events named by the culture captures an adult-centered definition (Spitzer, 2003). What about the idiosyncratic activities that children find to be interesting ways to spend their time, such as walking on a seesaw (Figure 3.1) or jumping on a bed (Figure 3.2). These "invented occupations" might be accepted in special situations, such as at grandmother's home, but are not typically encouraged. Here, *occupations* are defined as coherent patterns of action that emerge through transactions between the child and environment and are things the child wants to do or is expected to do (Humphry, 2002; Spitzer, 2003). The environment is composed of people, materials, time, and

FIGURE 3.1   Walking on the seesaw is a child's "invented occupation" that is not typically encouraged.

FIGURE 3.2   Jumping on the bed is another "invented occupation" that might be tolerated by a relative and not permitted by the parents.

space that have meaning relative to children's potential occupations. Thus, children's occupational performance emerges from both their capacities to act and their interpretations of these meanings. Reasons for engaging in occupations can be the child's interest as well as to achieve an outcome. Or children may engage in occupations because other people create situations that make engagement meaningful. The definition of *occupation* is broad to include children's exploration and play behaviors that have no other names. However, these child- and situation-specific occupations do not reflect broader **cultural practices**, a community's routine way of doing things and common appreciation of an occupation's importance (Gallimore & Lopez, 2001; Miller & Goodnow, 1995; Rogoff, 2003). Cultural practices are seen in more conventional occupations, such as playing tea party (Figure 3.3). This chapter focuses on the development of conventional occupations, those expected of children by their communities, but I encourage you to consider the role unconventional occupations have in children's well-being.

WHAT IS DEVELOPING AND WHAT IS DEVELOPMENT?

By engaging in occupations, children meet their current interests and needs while also learning from their environments, mastering skills and ways of behaving they will need when they are older. When children are at risk for not doing the valued and expected occupations or do not perform to their own or others' satisfaction, occupational therapy practitioners work with families, teachers, and other team members to advance the children's performance in conventional occupations. Critical to successful practice with children is the way in which occupational therapy practitioners conceptualize development and the change
process. These ideas are organized into different models of practice that lead to alternative forms of service. This chapter explores different ways of thinking about development, contrasting assumptions about what determines the things children do, and the forces that transform their occupations. I suggest that a way of framing the issues is

FIGURE 3.3   Playing tea party is a conventional occupation for children.

FIGURE 3.4 Building sandcastles is an intergenerational occupation for this grandmother, her daughter, and her granddaughter.

to shift the focus from development of an individual's performance capacities to development of occupations in a social context.

Before discussing the change process, it is important to think about what it means to develop an occupation. To explore what this entails, consider Figure 3.4, in which a grandmother, her adult daughter, and her preschool-age granddaughter are making sandcastles. The grandmother learned the practice of making sandcastles as a way of being at the beach from her parents, and she shared it with her children. Thus, though it is new for this preschooler, the occupation of making sandcastles on the beach has roots that cross generations. Development of an occupation builds on a framework of other people's experiences.

Though the picture captures a moment in time, the reader can imagine that making a sandcastle with a child unfolds as a communal project with an uncertain outcome. However, the grandmother and the adult daughter share an unspoken appreciation of the essential characteristics that define a sandcastle, procedural knowledge, and a sense of why it is meaningful to build one. To varying degrees, these ideas are shared by other people who have made sandcastles. Cultural practices then organize and coordinate the adults' actions, their tool use, and how they guide the preschooler's participation in making sandcastles. The preschooler, without explicit teaching by her mother or grandmother, comes to share their ideas about sandcastles, the options for actions offered by toy shovels and buckets, and what is significant about making sandcastles at the beach. Development of an occupation then is part of an unfolding social situation and mastery of cultural practices.

Finally, development captures both continuity and changes in occupations that occur over two different time spans. In the context of working beside two other sandcastle makers, the girl modifies her performance to enact

her evolving understanding of the occupation. Within the time frame of a day at the beach, the preschooler's knowledge and performance undergo transformations that can be described as learning. Over months and years, she will make sandcastles with other people and on her own, and these cumulative experiences will further inform her understanding of making sandcastles and her experiences of what is significant about building them, and she will eventually create intricately designed and innovative structures. Development of occupation reflects changes in knowledge, meaning, and performance over these longer periods of time during which the girl comes to identify herself as an experienced sandcastle maker with a particular style of her own. Though different in the time frames, learning is connected to developmental change with many of the same origins, so learning can be thought of as microdevelopment (Granott & Parziale, 2002; Siegler, 2000).

The developmental mechanisms that need to be understood are those forces that initially lead to doing an occupation and how microdevelopment transforms how it is done and experienced. For centuries, generations of children have learned to do the valued occupations of their communities. The reader might wonder whether this knowledge is not already available; after all, parents, teachers, older siblings, and coaches help children learn to do their occupations all the time. But not all children have parents or teachers who can help them to master occupations. There may also be special circumstances that prevent children from developing the occupations needed for participation. So what should an occupational therapy practitioner know?

Our knowledge about children and what they do at certain ages arises from different sources. First, there are "commonsense" ideas that are generated by adults who care for and work with children. People make observations and talk among themselves about children's age-related behaviors and their changing occupations. In essence, people construct a set of ideas about childhood occupations. Because everyone in that community sees children and their occupations in a similar manner, commonsense knowledge is accepted as fact. Another source of knowledge about children and their occupations is anecdotal testimony of experienced people viewed as having authoritative knowledge. Individuals who have years of experience with many children may be viewed as having dependable knowledge. In occupational therapy, master clinicians frequently offer anecdotal information to new clinicians as they serve as clinical supervisors or give workshops based on their practice experiences. But can these forms of knowledge be applied more broadly than the situations in which they are formed?

Commonsense knowledge and anecdotal information are socially constructed, shaped by how a society views children at that time in history. This means that ideas about children and what they do change over time (Davis, Polatajko, & Ruud, 2002). These belief systems vary between communities, so children may engage in very dif-

ferent occupations (Larson & Verma, 1999; LeVine et al., 1994). For example, some societies believe that play has little importance for children's future, and 6-year olds are considered responsible enough to tend to livestock or care for a younger sibling (Rogoff, 2003). In the United States, 6-year-olds are seen as immature, and parents encourage their play as a way to learn skills. Diverse ideas such as these are so readily accepted locally that they are not held up to scientific critique. In an era in which professionals are expected to offer services based on evidence, occupational therapy guided only by common sense or anecdotal information is inadequate.

In an effort to have informed practice, occupational therapy has turned to the literature about children generated by researchers in other disciplines. Developmental theories of psychologists are seen as useful to occupational therapy, and students are encouraged to learn them (Edwards & Christiansen, 2005; Law, Missiuna, Pollock, & Stewart, 2005). The profession needs to consider several issues, however. First, much of the work has been carried out in North America and Europe, which limits generalization to other cultures. Second, scientists who study children come with questions based on the interests of their disciplines. Developmental psychology tends to emphasize the individual, and the theories are devised to explain changing psychological functions. Third, these classic theoretical models are dated and not considered by psychologists to be cutting-edge science (Lerner, 2002).

TWO PERSPECTIVES IMPORTED FROM DEVELOPMENTAL PSYCHOLOGY

Service providers, parents, and scientists start with different philosophical worldviews about how things work, which in turn shape the body of knowledge they use to explain what changes children's behaviors (Lerner, 2002; Meacham, 2004; Super & Harkness, 2003). Sometimes, change is explained as a product of forces in the environment. Other authors take a biological view of the child, explaining development as the result of a genetically driven program to become more mature. Both perspectives on how development works appear in psychology and occupational therapy literature.

Originally expressed in an almost mechanical, cause-and-effect perspective, learning theory focused on the power of positive or negative rewards in shaping the behaviors of animals and children (Lerner, 2002; Skinner, 1971). Bandura (1978) expanded on the social nature of learning and how self-directed behavior occurs as children strive to achieve observed outcomes. Royeen and Duncan (1999) noted that a behavioral perspective is not often identified in the occupational therapy literature but is frequently implied. In writing about a skill acquisition approach, these authors suggest that practitioners create environmental

supports and positive feedback to help children learn skills or subskills of targeted occupations. A developmental approach adds an understanding of the hierarchy from immature to more mature skills and uses positive encouragement so that the child practices the youngest skill level or occupational performance the child is not able to do (Hinojosa & Kramer, 1999). The form and frequency of feedback about performance are not stressed; rather, the body of knowledge emphasizes the sequence of changing behaviors. Lists of typical age-related milestones in play and self-care domains and the associated fine motor, gross motor, cognitive, and social skills are available (e.g., Case-Smith, 2005). Basing services on typical development, however, overlooks the reality that children with special needs may have their own unique ways of doing things. In addition, conceptualizing development as following a continuum and practicing the most immature form that the child cannot do might be developmentally appropriate, but it might not be age appropriate, leaving the child open to stigmatization.

In contrast, other developmental theorists have described the forces for systematic change as the result of an innate drive or a self-regulating program within the child. What generates this intrinsic drive to achieve an individual's potential has been a source of speculation among psychologists. Classic theorists in developmental psychology have alluded to an intrinsic need for psychosocial adjustment, knowledge, or mastery (Erikson, 1982; Piaget, 1952; White, 1959). In occupational therapy, a child's drive to engage in occupation is seen as the medium through which the child brings about development of his or her own abilities to do occupations (Primeau & Ferguson, 1999). When children have occupational performance difficulties, practitioners are encouraged to work for an optimal match between person, task, and environment. This may include remediation of underlying performance components using neurodevelopmental approaches. Instead of occupation, the focus then became one of using therapeutic activities to change the organization of the nervous system and develop ability (Law et al., 2005). However, therapeutic activities that are created for sensory or motor experiences lack contextual meaning that arises from the child's natural environment; thus, they are contrived rather than being children's true occupations (Fisher, 1998).

Without evidence that either a developmental skills approach or neurodevelopmental interventions are effective (Mahoney, Robinson & Fewell, 2001), occupational therapy practitioners have adopted eclectic practices. For example, Case-Smith (2000) describes preparatory therapeutic activities drawing on a sensory integration approach and then graded motor practice to build fine motor skills using playful interactions to reinforce the child's efforts in challenging occupations Other authors suggest that young children's development may be explained by experiences that somehow trigger biological growth of their capacities but that development of school-age children is explained

TABLE 3.1	PROPOSED MECHANISMS BRINGING ABOUT CHANGE IN OCCUPATIONS
Broad Categories	**Proposed Change Mechanisms in Development of an Occupation**
Societal investment in children's occupations	Communities invest in childhood occupations and express normative expectations that children at particular ages participate in these occupations.
	People in the community hold socially designated roles with responsibility for orchestrating children's time and supporting valued occupations.
Interpersonal influences on occupational engagement	Vicarious learning from familiar people engaged in their occupations informs children about occupation. As active onlookers, children learn about possible outcomes and what is significant in occupations.
	During shared occupation performance demands are distributed between participants and children learn new information about the outcomes and meanings of the occupation.
	Explicit teaching and scaffolding of the occupation brings the child's performance to a higher level. The more experienced partner introduces more culturally influenced ideas about outcome and meaning.
The dynamics of doing an occupation	Challenges to familiar ways of doing things lead children to try to new combinations of their capacities, contributing to discovery of new performance strategies. Gradually, children learn to select performance strategies to fit particular situations.
	Altered experiences of outcome and significance of the occupation leads the child to find new performance strategies.
	Performance and capacities are interrelated with reciprocal influences from multiple levels of change. In this way, experiences in occupation furthers development at multiple levels, which is then available so that the child's performance in the occupation reflects the practices of the community.

by forces in their environments (Cronin, 2005). If this were the case, then neurodevelopmental approaches would be appropriate for infants and preschoolers but not for school-age children. In summary, the strategy of adopting developmental psychology's theories about children has not generated a coherent body of knowledge that focuses on development of occupations.

A THIRD PERSPECTIVE ON THE DEVELOPMENTAL PROCESS

Recall the example at the beginning of the chapter, in which a preschooler learns from her mother and grandmother to make sandcastles. This and other conventional occupations are socially constructed, determined by children's cultures. Thus, the body of knowledge that informs occupational therapy cannot be just about development of capacities of individual children. Our understanding needs to be contextual, seeing the person-situation as a functional whole system (Dickie, Cutchin, & Humphry, 2006). From this perspective, occupation is the way in which a person engages with the environment. Research on people's occupations and theories of development that grew out of the ideas of Russian psychologists such as Vygotsky and Luria and the writing of the pragmatist philosopher Dewey

(e.g., Engestrom, Miettinen, & Punamaki, 1999; Gallimore & Lopez, 2002, Goncu, 1999; Rogoff, 2003) contributed to the ideas presented below.

I asked what constitutes an appropriate model to guide occupation-centered practice with children and engaged in a series of two observational studies of children in child-care situations to find out how children learn to do the things that they do. A different way of thinking is outlined below, with examples drawn from my observations (using pseudonyms). First, I studied typically developing infants in a child-care classroom. Then I observed preschoolers with special needs and their classmates who showed typical development. I watched while children in both groups learned cultural practices such as "Ring Around the Rosie" and do songs with associated gestures or movements. These occupations became classroom routines and a way in which children connected with each other (McNamara & Humphry, in press).

Developmental mechanisms identified in this chapter are forces that act synergistically to bring about engagement in an occupation and transform how it is done and experienced (Humphry, 2005). These changes occur on a micro-developmental time scale, and gradually, over months and years, the occupations develop. For the reader's ease in tracking major concepts, the mechanisms are listed in Table 3.1, organized into three broad categories.

Societal Resources Bringing About Development of Childhood Occupations

By moving the focus away from development of the individual to development of occupation, it is easier to see sociocultural features in everyday occupations and how these are part of the developmental process. Ann Wilcock (1998) argues for the concurrent evolution of *Homo sapiens'* occupational and cultural nature so that as groups of people worked collaboratively, their shared goals, values and standards created cultural practices. Singing to or sharing music with children reflects a cultural practice that takes many forms around the world and occurs regularly in the United States (Custodero, Britto, & Brooks-Gunn, 2003). The societal investment in children's occupations is reflected by creation of things for children to do and manufactured objects for their occupations (Mouritsen, 2002). In the infants' class, there were toy radios adapted to the developmental abilities of young children. The preschool had child-sized musical instruments. Songs written for children, such as "The Wheels on the Bus," were a regular part of the preschoolers' circle time.

Another societal investment in children's occupations is the commitment of human resources. Every community has people who hold socially designated roles to oversee children's engagement in occupations that are valued and expected of children. Rogoff, Paradise, Arauz, Correa-Chavez, and Angelillo (2003) observed that when children are not routinely brought into the adult occupations of their communities, special child-focused occupations are created for them. In the United States, parents manage the space at home, offer child-focused occupations, and serve as play partners (Pierce & Marshall, 2004; Rogoff et al., 2003). In the classrooms, the lead teachers in each classroom had degrees in early childhood education and took charge of organizing classroom routines on the basis of their educational objectives. For the preschoolers, doing songs was designated as part of "circle time," while music was less formal for the infants; their teacher sat with a couple of children and engaged them in songs.

In occupational therapy, understanding the societal influences on development of occupation is informative. Part of the commonsense information that is shared in a community is what children like to do at different ages. These occupations carry **normative expectations**, through which a community shares the understanding that by a certain age, children will behave in a particular way. So parents and educators may refer children for services if children are not participating in expected occupations. Also, children are rarely part of just one community, so the cultural practices and normative expectations of their families and those of the child-care centers and educational programs can be different. The occupational therapy practitioner will want to hear about the occupations that are expected in different situations.

Interpersonal Influences on Occupational Engagement

Before moving into the interpersonal processes, I first consider children's experiences of occupation. Children's behaviors in doing different occupations are organized into intentional efforts in order to experience effects that are significant to them or to achieve the outcomes that they have in mind (Humphry, 2002; Spitzer, 2003). Infants who were a year old had ideas about specific occupations and asked adults to do something in particular. For example, Helen approached a visitor, carrying a book on the ABCs. She handed the book to the visitor and sat beside the woman, who obliged by reading the first pages. However, Helen stood, took back the book, and gave it to her teacher, who sang the ABCs. Helen seemed satisfied and sat through the song, looking at the pictures. In essence, the book was Helen's way of naming what she wanted to do. When her communicative act failed to elicit the expected routine from the visitor, Helen sought out a more informed companion for her occupation. The example illustrates young children's awareness of occupations as distinct, with unique significance and expected outcomes. This section addresses how children build this understanding in the context of their everyday lives.

As was seen in the earlier example of learning to build a sandcastle, interpersonal connections in a social situation with familiar people are critical to the development of occupations. Occupational therapy practitioners seek indicators of learning about occupations and capitalize on these processes in working with children who are at risk for delays (Humphry & Wakeford, 2006). The social milieu created by people who are engaged in a variety of occupations forms a powerful interpersonal change mechanism. The act of watching supports vicarious participation in occupations before young children actually do things. Children, anticipating that they will one day do particular occupations, watch other people do things with a higher degree of intensity (Rogoff et al., 2003). In this context, children acquire information about how to do the occupation and what constitutes satisfactory performance. They also develop ideas about the outcomes and gain a sense about the occupation's significance. Children, in onlooker roles, are active participants, learning about an occupation well before they engage in it.

There is controversy over children's abilities to interpret what other people do as intentional (Reddy & Morris, 2004). One group of developmental psychologists suggests that before children interpret other people's actions as intentional, they need to have the mental appreciation that another person's actions are guided by that person's mind ("theory of mind"). An alternative, more contextual argument is that young children are not separated from familiar people who are engaged in their occupations. Children do not need abstract concepts such as how other

people's actions are guided by thoughts before understanding another's acts as purposeful; rather, children are sensitive to the organized, focused flow of people through their emotional engagement (Reddy & Morris, 2004). There may be a physiological basis for this assertion. Recent work on so-called mirror neurons supports the possibility of vicarious participation, even among other primates. Rizzolatti, Fogassi, and Gallese (2006) explained that they found, in nonhuman primates and human volunteers, a subset of neurons that respond, by becoming active, to observations of a researcher moving to pick up food. The pattern of activation was the same as it would have been if the nonhuman primate or person was himself or herself reaching for food. In other words, the observers were mentally sharing the experience of moving in a functional manner. These scientists argue that through the activation of mirror neurons, a person has firsthand experiences of another person's act, intention, and emotions. Though further research is needed, it could explain how children are able to learn about how to do occupations by watching.

For example, one of the preschoolers, Joshua, was physically and intellectually challenged and was unable to stand unaided because of his fluctuating muscle tone. He frequently participated in circle time while positioned in a stander, so he was unable to move his legs. He could and did join his classmates by raising his arms in the part of the "The Ants Go Marching" song about the ants climbing out of the ground and watched as they marched to other parts of the song. Joshua demonstrated that he had not been a passive onlooker when one of the classroom aides helped him to join the group by holding him under his arms in supported standing. He grinned and stepped at the time in the song when the ants were marching. Both the aide and the teacher commented on his glee at doing what he had seen other children do.

In Table 3.1, in the category of interpersonal influences, the second and third proposed change mechanisms have many common features. Children can move back and forth between learning through vicarious engagement and joining in a shared occupation with either a peer or a more experienced partner. There are two ways in which sharing an occupation promotes its development. First, when children do something together, they organize their performance around their shared situation, in essence, cocreating the occupation. In coordinating their actions to sustain their engagement, the performance demands are distributed among participants. Thus, one child may model, point to, or offer hints to support a peer who is having performance problems (Johnson-Pynn & Nisbet, 2002). In this way, performance challenges are shared among participants, contributing to their acquisition of new performance skills. While supporting one another in their occupation, children also introduce variability, challenging each other to invent new ways of doing things.

The second aspect in the interpersonal change mechanism is the progression of a child's sense of the significance and expected outcome in the occupation. A child's ideas about the occupation are part of how the child interprets what is happening, part of his or her "situation definition" (Wertsch, 1999, p. 69). As peers coordinate their actions, individual situation definitions are shared through facial expressions, words, and actions, so as the occupation unfolds, they exchange feelings about meaning and purpose. In this way, participants in an occupation achieve a mutual understanding that is different from their original situation definition. These altered or new experiences of significance and expected outcomes change performance and become part of the child's situation definition the next time the opportunity for that occupation is perceived.

Lawlor (2003) pointed out that at times, the significance of an occupation rests primarily in the sense of being socially engaged. Even when the child might hesitate to do something, the fact that it includes another person might be sufficient to get the child to take up the occupation. This phenomenon, finding meaning in being part of a group, is described as "togetherness" and is thought to be linked to a feeling of belonging (van Oers & Hannikainen, 2001). What is important is that as part of the child's situation definition, even if the child is engaged in the occupation alone the next time, he or she retains a sense of belonging to a larger group defined by the occupation.

For example, in the infant classroom, Anya sat with a toy radio on a mattress. She turned the radio on by pushing a lever, and it played "She'll Be Coming 'Round the Mountain." A younger classmate walked over and sat beside Anya. In sitting, Anya swung her arms and twisted her shoulder to the music. She looked at the classmate, who rocked back and forth at the waist while the music played. They smiled as they looked at each other dancing. Observations of Anya dancing were repeated throughout the study, and I concluded that her situation definition when she used musical toys included belonging to a group of dancers.

One of the commonsense ideas that occupational therapy practitioners may hear is that children have to demonstrate readiness skills before they engage in an occupation. For example, one might argue that before a young child or person with intellectual challenges can understand the meaning and outcomes of a shared occupation, he or she needs communication skills. An alternative is to recognize that in the context of experiencing dancing together, the infants' communicative acts (gestures, rhythmic movements, child-to-child regard, smiling) defined their togetherness as a significant element of dancing to music. Their coordinated interactions are transactional; one child gestured or looked, and the other child interpreted the expression and smiled communicating her experiences to the first child (Budwig, 2003; Reddy & Morris, 2004). Rather than defining abilities as prerequisite to occupation, the occupational therapy practitioner realizes that by shar-

How an Experienced Person Can Support a Child's Engagement in a Challenging Occupation

1. Playfully encourage the child to do an activity that otherwise has little meaning.
2. Fill in performance gaps, doing difficult parts of the activity.
3. Suggest different ways to do the activity.
4. Introduce and model the use of new objects in the activity.
5. Add relevant information about the activity.
6. Introduce alternative outcomes.
7. Bring in more culturally shaped meanings regarding why the activity is significant.

ing an occupation, the child enters a situation in which the needed abilities are elicited and practiced.

The power of a shared occupation takes on additional weight as a change mechanism when the other person holds a socially identified role with expectations for explicitly teaching, scaffolding, or guiding children's participation in occupations (Rogoff, 2003; Valsiner, 1997). As adults and children coconstruct an occupation, the adult initially adjusts to the situation definition of the child (Wertsch, 1999). Once the connection of doing the occupation together is established, the adult introduces new definitions of significance and expected outcomes reflecting the cultural practices of the community. Box 3.1 lists ways in which the experienced person contributes to development of occupation.

In my observations, the presence of other people was a central element to the development of occupations, and the teacher sometimes took advantage of group situations. For example, when engaging the toddlers in "Ring Around the Rosie," the teacher called the attention of younger children to the behavior of the older classmate who had learned to squat when the song came to "we all fall down." Peer learning did not always occur, though, when the teacher thought an occupation belonged to an individual. When Joshua was set up with a switch that activated a musical toy, he showed limited interest and did not persist in reaching for the button. When the teacher left, Joshua lost all interest until a classmate used the switch and toy. This refocused Joshua's attention on the music. He watched his classmate push the switch and play music until the teacher returned and told the classmate, "Don't touch this toy, it's for Joshua." Sending his classmate away so that Joshua could practice reaching for the switch interrupted

his learning about the expected outcome of using the switch and the social significance of music.

The Dynamics of Doing

The societal and interpersonal change mechanisms discussed above are integrated with an understanding of the dynamic and contextual nature of occupational performance (Case-Smith, 2005, Humphry, 2002, Kielhofner, 2002). The coherent patterns of action in occupation reflect **emergent performance,** the unique integration of abilities in actions. Different combinations are brought together at that time and in a particular situation. Thus, how something is done is not predetermined, and the combined use of the child's sensorimotor, psychosocial, and cognitive abilities in acting are interdependent, influencing each other. Furthermore, a child's ideas about the occupation and affordances in the environment determine occupational performance (American Occupational Therapy Association, 2002; Law et al., 1996). This stands in contrast to thinking of occupational performance as being determined just by the maturation of particular abilities intrinsic to the child. At one time, the appearance of a new skill, such as picking up a Cheerio between the index finger and thumb or skipping, was thought to reflect the maturation of motor section of the nervous system. However, it is now recognized that performance is influenced simultaneously by a variety of body structures and functions and by various features of the situation (Thelen, 1995). Kevin, for example, knew the lyrics of a song about the ABCs. He sang it while jumping on a trampoline in the preschool classroom. However, his occupational performance, singing, was changed by the context. When the same song was sung as part of circle time, Kevin participated as an onlooker, finding the social situation too demanding for singing. This phenomenon—that occupational performance emerges from the child-environment as a functional system—is the basis for the change mechanisms described below. These changes primarily reflect microdevelopment, subtle shifts in performance strategies that accumulate over time to transform performance, reflecting development of occupation.

Three interlinked change mechanisms occur as a child engages in doing an occupation (see Table 3.1). First, in response to performance challenges, a child recruits and rearranges his or her abilities, using existing abilities in new ways to continue engagement. Challenges arise from new environments, novel objects used in the occupation, or changes in how another person collaborates in doing it (as was suggested above). When a familiar way of doing the occupation fails, the child tries different combinations of capacities. In a trial-and-error process, the child functions sometimes at higher end of his or her performance range (Siegler, 2000). The child learns which new combinations of capacities work and in what conditions, employing more often the strategies that achieve the expected outcome and

selecting more accurately what strategy fits a particular situation. In this way, engagement in the occupation leads to more refined performance and builds towards generalization across contexts.

For example, during circle time, the teacher sang the song "Where Is Thumbkin?" and encouraged the children to hold their fists up and extend their thumbs. Ari held up both hands, pointing with his index fingers at the ceiling (a familiar hand movement). The teacher modeled again and said "thumbs up." Ari held up an open hand and watched as he closed his fingers. (He used visual feedback to get his thumbs extended.) The next week, when his teacher announced that the next song was "Thumbkin," Ari seemed to remember what he needed to do. That time, though, he started with his left fist and pried his thumb up with his right hand. However, he could not maintain the left hand fisted when he shifted his effort and tried the same prying procedure with his right hand. That day, he did the song with one hand. With repeated practice of different strategies, Ari eventually used sensory feedback from muscles and joints to maintain his hands in the correct position so that he could do "Thumbkin."

Changes in a child's understanding of the outcome or ideas about significance in doing an occupation also alter performance (Humphry, 2002). As was discussed above, watching other people do things and coconstructing an occupation with others alters the child's situation definition about an occupation. Children can also discover their own new ideas about the outcomes or experience some aspect of the occupation as more interesting than before. Even when an occupation seems to be routine, a new meaning changes how it is done. For example, part of the circle routine was to sing a good morning song, and each verse greeted one of the preschoolers by name. The children sat and clapped their knees as the teacher sang a verse. In time, Molly realized that one verse specifically named her. From then on, instead of clapping her knees when it was her turn to be named, she smiled and shook her head for that verse.

Finally, though maturation of capacities does not completely explain changes in occupational performance, capacities do change with use. In a broad biological sense, development of a child occurs simultaneously at several levels, including genetic activity, body structure, the functions of body systems, capacities, and performance (Gottlieb, 2000). Furthermore, there are reciprocal influences across levels. This means that as children use their capacities, repeated experiences changes these levels and directly or indirectly bring their capacities and performance to higher states of maturity. Subsequently, more mature capacities become available and occupational performance changes. However, the situated and emergent nature of performance in context needs to be remembered. When occupational performance was thought to be a product of the maturity of certain parts of the nervous system, any therapeutic activity that challenged the functional capacity that was

thought to be "immature" was believed to lead to further maturation of that part of the brain. This assumption that performance comes from within the child and is uninfluenced by the child's the situation and occupational opportunities led to the developmental skills approach that emphasized components of performance.

For example, Lyle, who was born with Down syndrome, watched his preschool classmates doing songs by clapping, raising their arms or marching. He participated only when adults took his hands in theirs and helped him to clap or do hand gestures. His interest in the occupation but inability to plan and sequence movements efficiently is consistent with his genetic disorder (Fidler, Hepburn, Mankin & Rogers, 2005). Using a developmental skills approach, intervention might include therapeutic activities with repetitive, sequenced acts such as stacking blocks and drawing circles on a chalkboard to remediate Lyle's problems with planning. In light of what we now understand about the emergent and situated nature of performance, the most effective way to draw on developmental mechanisms described here is to help Lyle participate in songs. This could be done by using hand over hand, direct teaching, or slower songs or by giving him time to move and approximate others while doing songs.

CONCLUSION

Occupational therapy is indicated when a child is unable to do conventional occupations such as spending time at the art table, engaging with a parent in bedtime routines, or eating lunch with classmates in the cafeteria. How occupational therapy practitioners conceptualize the change process determines how they practice. This chapter outlines a way of thinking about development that takes a contextual perspective in which occupations are a way of connecting the person with their environments (Dickie et al., 2006). Understanding the developmental process requires knowledge of the circumstances surrounding childhood occupations. Conditions to consider include the origins of the occupation and an appreciation of the child's present situations. For example, children are members of a variety of communities that create different occupational opportunities. Thus, distinctive occupations can be coconstructed and shared with a range of people in different contexts. These ideas are important, since development of occupation occurs because children and their environments form a functional system, something that is understood in its entirety. The forces of change include the societal, interpersonal, and dynamical processes and work synergistically. Application of these ideas has been made to practice with children (Humphry & Wakeford, 2006). Microdevelopment and development occur over the entire life course, and implications of this developmental model for work with people of other ages await further exploration.

PROVOCATIVE QUESTIONS

1. Children in other countries perform differently from children in the United States on standardized assessments that are thought to measure internal capacities such as manual dexterity, balance, and perceptual-motor skills. On the basis of the developmental mechanisms described in this chapter, what explains this finding? What are the implications for children who have special needs?

2. Select one of your childhood occupations (e.g., drawing pictures, soccer, eating dinner with the family). What were societal and interpersonal influences that contributed to development of your occupation?

3. In this chapter, you were encouraged to think about the importance of idiosyncratic occupations that children find to be interesting ways to spend their time. How do these occupations contribute to their well-being? Given the nature of the developmental mechanisms discussed above, would you expect these unconventional occupations to change over time?

Understanding Family Perspectives on Illness and Disability Experiences

MARY C. LAWLOR AND CHERYL MATTINGLY

Learning Objectives

After reading and reflecting on this chapter, you will be able to:

1. Discuss ways in which family members experience illness and disability and how these experiences are situated in family life.
2. Recognize the expertise that family members have and bring to health care encounters, including occupational therapy sessions.
3. Understand the health care encounter as a complex social arena in which perceptions and decisions about care are created, contested, and negotiated by multiple social actors.
4. Describe knowledge, skills, and behaviors that facilitate effective "partnering up" and collaboration.

So, what I did is, I became very personal with my therapist. She just wasn't a lady I saw once a week; she was adopted into my family. And I brought my family to therapy with me. I brought children. I brought my grandma (laughs), so that she could be in on what it is that we would be trying to achieve. What it was that we need my daughter to accomplish. I brought children, aunties, uncles, close neighbors—everybody that was a part of my close daily surroundings, went to therapy. And that's just the way it

was. So that the therapy was not just once a week, it was seven days a week. It was from the minute we woke up to the minute we went to bed.

The above quote is an excerpt from a transcribed interview with a mother who was telling a story about her daughter's occupational therapy program. It is drawn from an ethnographic research study conducted by the authors and an interdisciplinary research team that will be described in more detail below.[1] This brief passage illustrates the ways in which health care encounters, including occupational therapy, are collaborative efforts that are centrally situated in family life. Health care encounters are not only specific events, but also episodes in the histories of client and family life and, conceivably, also episodes that are embedded in practitioners' lives and institutional cultures. Encounters such as occupational therapy sessions, particularly ones in which significant experiences happen, are events in longer illness and developmental trajectories. Significant moments in therapy sessions may resonate across time to other moments in one's life and across place to the extent that the impact is felt in other contexts, such as life at home, school, or work. In a similar way, salient moments in home and family life may influence health care encounters and the happenings that occur in occupational therapy sessions.

This chapter addresses the need to attend to family perspectives in providing services to people with chronic illnesses or disabilities and the experiences of family members that are related to their participation in occupational therapy services. The **family-centered care** movement, cost containment initiatives, and technological advancements in care delivery have fundamentally altered the expectations of families and practitioners, the nature of health care and caregiving practices, and outcomes of interventions. Health care encounters, once characterized by dyadic communication between a patient and doctor, are now complex social arenas in which multiple social actors, including family members, convene. Health care encounters involving family members are sites of intense **boundary crossing** where families and practitioners create, negotiate, contest, and/or modify perceptions, perspectives, and caregiving and treatment practices. Multiple perspectives on health care events are both anticipated and managed within often relatively brief moments of interaction. Some of the interesting dilemmas and opportunities that emerge when practitioners involve families actively in the therapeutic process are highlighted in this chapter.

---

[1]The data that are used in this chapter are drawn from a longitudinal study funded through three sources: *Crossing Cultural Boundaries: An Ethnographic Study* (MCJ Grant # MCJ 060745); *Boundary Crossing: A Longitudinal and Ethnographic Study* (NICHD, NIH, #1 R01 38878); and *Boundary Crossings: Re-Situating Cultural Competence* (NICHD, NIH, #2 R01 38878). Pseudonyms are used to provide greater confidentiality.

We begin by arguing for the need to bring families into the picture in a central way and by discussing the recent movement (largely in pediatrics) toward family-centered care, raising some questions about what this term might mean in practice. We look at why families have been so peripheral in the way in which most health care professions have defined their practice and discuss how involvement of family members in health care fundamentally changes the nature of the encounter. The heart of the chapter moves from these more general considerations to the intricacies, dilemmas, surprises, and riches of therapeutic work that takes seriously the illness and disability experiences of families. Processes related to "partnering up" between practitioners and family members are also examined.

WHY ARE FAMILIES IMPORTANT IN HEALTH CARE?

Common sense tells us that most people who come to occupational therapy live in social worlds that include families of some kind. Even when people live apart from their families, it is very likely that some family members will be instrumental in caregiving in some way. Even in those instances in which no family member is actively involved in care, it is likely that someone from the client's family will be concerned with this care, including the services of the occupational therapy practitioner. Furthermore, the way in which clients experience disability and how it affects their functioning in the world often depend heavily on the clients' relationships with family members and other significant people in their social worlds. This is most obvious in pediatric care when the client is a very young child and in geriatric care when spouses and adult children become involved in care. Families, in various forms and partnership arrangements, tend to matter for most people who experience illness or disability, no matter what the age, ethnicity, socioeconomic status, or geographical location. Not only do families matter, but families shift in response to the issues raised by having a family member with an illness or disability. Roles change. Power relations change. Activities change. The way in which meals are eaten, vacations are taken, disputes are negotiated, beds are made, money is earned, and houses are organized, as well as other aspects of family life, are likely to be affected.

The implementation of federal initiatives related to providing services for children with special health care needs and their families was documented as early as 1912, with the establishment of the Children's Bureau in Maternal and Child Health (Hanft, 1991) and expanded with the implementation of Title V legislation in 1935 (Colman, 1988). The implementation of P.L. 94-142, Part B, an amendment to the Education for the Handicapped Act (EHA) in 1975, and P.L. 99-457, Part H, an amendment to the EHA in 1986, prompted dramatic changes in the nature of service delivery to children in educational and

early childhood settings (Hanft, 1991; Lawlor, 1991). In 1990, EHA was renamed the Individuals with Disabilities Act (IDEA, P.L. 101-476). Implementation of these services placed new demands on practitioners to reframe traditional medical models of practice to accommodate to the needs of families as well as the child who was referred for services (American Occupational Therapy Association, 1999). In 2004, IDEA was reauthorized, and although much of the language around family participation has changed, many of the earlier principles have been retained. For example, the new statute still incorporates an Individual Family Service Plan as one of the minimum requirements for a statewide system's provision of services for each infant or toddler with a disability and the family of that child (108th Congress, 2004).

Family-Centered Care

Although the development of services that center on the needs and values of families began in early childhood programs through family-centered care initiatives (Hanft, 1991; Lawlor & Mattingly, 1998), many of the principles apply to services for people of all ages (Humphry, Gonzales, & Taylor, 1993). As human service systems moved into the community and family members began providing home care, practitioners developed a deeper appreciation of the centrality of families in healing, recovery, and adaptation. Practitioners also recognized that family members often had different perspectives from those of the professionals about the needs, priorities, and strengths. This recognition led to a shift from perceiving family members as people who will carry out the doctors' and practitioners' orders to perceiving family members as people who are most knowledgeable about the client and who are partners in decision making. Family members' perspectives about how the client is doing, what the client needs, what the family needs, and what is most important and meaningful in everyday life have become part of the clinical dialogue.

Family-centered care involves much more than thinking of adding family members into the therapy session; occupational therapy practice is fundamentally altered when family members are brought into the therapeutic process in a central way (Lawlor & Mattingly, 1998). Family members, including parents, often have powerful roles in the creation of significant experiences in therapy (Mattingly & Lawlor, 2001). The challenge for the occupational therapy practitioner is to collaborate with clients, their families, and other team members in designing a program that builds on strengths and addresses needs. When done successfully, intervention services are individualized to each family and reflect their unique cultural world. Drawing on the work of Dunst, Trivette, and Deal (1988), we have defined family-centered care as *an experience that happens when practitioners effectively and compassionately listen to the concerns, address the needs, and support the hopes of people and their families* (Lawlor & Cada, 1993; Lawlor & Mattingly,

1998). Sometimes practitioners can best involve clients and families in the decision-making process by offering multiple options for interventions (Rosen & Granger, 1992). This type of engagement is often described as a means of enabling and empowering families (e.g., Deal, Dunst, & Trivette, 1989).

Family-centered care is enacted through the collaborative efforts of family members and practitioners (Edelman, Greenland, & Mills, 1993; Lawlor & Mattingly, 1998) and typically is provided through multidisciplinary and interdisciplinary team structures. Partnerships are created on the basis of the establishment of trust and rapport as well as respect for family values, beliefs, and routines (Hanft, 1989). Additional elements of successful collaboration include clarity and honesty in communication, mutual agreement on goals, effective information sharing, accessibility, and absence of blame (McGonigel, Kaufmann, & Johnson, 1991). Successful collaboration occurs when practitioners and family members form relationships that foster a shared understanding of the needs, hopes, expectations, and contributions of all partners (Lawlor & Cada, 1993).

The Processes of "Partnering Up" and Collaboration

Collaboration is much more than being "nice" (Lawlor & Mattingly, 1998; Mattingly, 1998). It involves complex interpretative acts in which the practitioner must understand the meanings of interventions, the meanings of illness or disability in a person and family's life, and the feelings that accompany these experiences. Collaboration is also dependent on the development of a quality of interrelatedness that is evident in many therapy sessions that is not merely a question of establishing good rapport, eliciting cooperation, or prompting a client or patient to buy into a particular agenda in order for him or her to perform required tasks (Lawlor, 2003). The central question for practitioners, clients and their families is "How can we come to know enough about each other to effectively partner up?" (Lawlor & Mattingly, 2001). For therapists, the nature of the work in collaboration "is not merely technical in the sense that a procedure is done or a therapy or other intervention is provided, nor does the work just entail drawing upon clinical expertise. Rather, 'partnering-up' requires skilled relational work and involves the drawing upon a range of social skills including, intersubjectivity, communication, engagement, and understanding" (Lawlor, 2004, p. 306). Assumptions about race, culture, ethnicity, social status, economic level, and education (and frequently the contesting of these assumptions) often powerfully influence the process of "partnering up" between families and professionals. Family members and practitioners live and operate in a multiplicity of cultural domains that are shaped by their profession, economic class, ethnicity, and community affiliations. When

practitioners and family members interact, their values, assumptions, and perceptions about the interaction are shaped by their membership in these cultures.

"Partnering up" also involves bridging differences, establishing points of common interests and mutuality, and capitalizing on complementarities. This aspect of collaboration is particularly important when family members and practitioners perceive that they come from seemingly differently lived worlds. Mattingly (2006), drawing on reconceptualizations of culture that are prevalent in current anthropology, argues that health care encounters are like border zones, where there is often heightened engagement related to marking differences, finding commonalities, and creating understanding. Families in many ways are the consummate travelers in border zones with the daunting task of coming to understand biomedical, institutional, and practitioner cultural worlds and practices and participating in these practices in such a way that their nonbiomedical conceptualizations of their children, their families, and illness and disability can shape health care encounters.

Developing Understandings of Illness and Disability Experiences

Although increasing attention is being paid to family members, families are systematically underconsidered when it comes to health care. Professional training, institutional structures, reimbursement procedures, and reward systems all tend to contribute to the marginalization of families. When occupational therapy practitioners do try to consider the needs of their clients and of family caregivers, they can find themselves addressing a range of issues and facing a number of dilemmas for which they might not feel prepared.

The easiest way to understand why families have not traditionally been better included in decisions about health care is to remember that health care professionals, including occupational therapy practitioners, are members of professional cultures and work in settings that have institutional cultures. All health care professions have been powerfully influenced by what anthropologists sometimes call the "culture of Western biomedicine" (B. Good, 1994; Hahn & Gaines, 1985; Jackson, 2000; Locke & Gordon, 1988; Rhodes, 1991). It is a bit deceptive to speak of one monolithic culture of biomedicine, as though this were some single homogeneous entity. Occupational therapy practitioners, for example, might find that they live only partly in the same professional culture as, say, neurosurgeons. And practitioners working within one setting might find that this institutional culture is quite different from another setting in which they have practiced. This can hold true even if both organizations appear outwardly similar—two different rehabilitation hospitals, for instance. But even if all these differences and nuances are kept in mind, there are a number of powerful assumptions that are shared at some level by many health professionals working across a wide variety of settings.

Not only do professionals such as occupational therapy practitioners learn professional skills when they enter the field, they also assimilate a set of values and beliefs that make them members of a professional culture or community of practice (M. J. Good, 1995; Wenger, 1998). The culture of biomedicine has developed over the past 250 years.[2] Biomedicine has provided a powerful view of what it means to be ill and what is expected of the client, the health care professional, and the client's family or key caregivers (B. Good, 1994). There are some deeply held beliefs about what constitutes an appropriate relationship among professional, client, and family caregivers. These assumptions about the professional-client-caregiver relationship are influenced, in turn, by other basic assumptions about the nature of illness and how it is best treated. Some of these assumptions are especially problematic for rehabilitation professionals such as occupational therapy practitioners who treat clients with chronic illnesses and disabling conditions.

Attempts to understand illness and disability experiences have been facilitated by the "narrative turn" in medicine (Garro & Mattingly, 2000a; Hurwitz, Greenhalgh, & Skultans, 2004). As Garro and Mattingly (2000b) note, "An important thread in the literature which has emerged from or is directed toward the clinical community and aspires to reorient medical practice in society, is the need to distinguish disease, as phenomena seen from the practitioner's perspective (from the outside), from illness, as phenomena seen from the perspective of the sufferer" (p. 9). Literature in anthropology, particularly medical anthropology, occupational science and occupational therapy, medicine, and other health-related fields are increasingly drawing on narrative approaches to (1) enhance understanding of illness and disability from the perspectives of the individuals and their families who are living with illnesses or disabilities (e.g., Bluebond-Langer, 1978; A. Frank, 1995; G. Frank, 2000; Kleinman, 1988, 2006; Monks & Frankenberg, 1995; Murphy, 1990); (2) analyze how narrative modes of reasoning or narrative-based ethics influence health and therapeutic practices (e.g., Becker, 1997; Cain, 1991; Charon & Montello, 2002; Fleming & Mattingly, 1994; Hurwitz et al., 2004); and (3) recognize narrative as a structure for creating significant experiences in therapeutic practices (Clark, 1993; Mattingly, 1998).

Occupational therapists have also found it helpful to read and reflect on first-person accounts of illness and disability experiences (e.g., Bauby, 1997; Greenfeld, 1978, 1986; Hockenberry, 1995; Park, 1982, 2001; Williams, 1992). At times, popular media, including films and television shows, can generate insights that support practitioners' reflections on their clinical practices. Even films or television shows that present portrayals of illnesses or disabilities or health and therapeutic practices that may be

---

[2]For a detailed reading of this history as a cultural phenomena, see, for example, Foucault, (1973, 1979).

disturbing, demeaning, or inaccurate can provide important experiences for clarifying beliefs and philosophies that are critical to the provision of efficacious, collaborative, and compassionate family-centered care.

TROUBLESOME ASSUMPTIONS ABOUT DISABILITY, ILLNESS EXPERIENCES, AND FAMILIES

Several key assumptions that are particularly potent and particularly tenacious (Gordon, 1988) in the culture of biomedicine and in occupational therapy have significantly influenced the way in which families are drawn into the therapeutic process. Although over the past twenty years there has been increasing attention toward understanding the ways in which family members participate in health care practices (e.g., Hinojosa, Sproat, Mankhetwit, & Anderson, 2002; Lawlor & Mattingly, 1998), much additional knowledge and reflection are needed (e.g., Cohn, 2001; Ochieng, 2003). Many practitioners who work in multicultural settings recognize the complexity of organizing health care and therapy practices in such a way as to understand and address the specific needs of family members who have diverse backgrounds. The following sections illustrate how problematic or flawed assumptions about the illness and disability experiences of family members can affect care.

The Disability Belongs to the Individual

One of the most pervasive assumptions in biomedicine is that the professional's task is to treat the individual who has the illness. Sometimes, this is narrowly interpreted among health professionals as "treating the pathology," but occupational therapy practitioners usually try to remember that they are also treating a person who has a disabling condition. The hand therapist is treating not only a hand injury, for example, but also an out-of-work auto mechanic who has a wife and three children. The therapist recognizes that this client whose hand was injured on the job is fearful about his ability to regain his role as family breadwinner.

Put differently, practitioners try to treat what anthropologists speak of as *the illness experience* rather than simply the disease (B. Good, 1994; B. Good & M. J. Good, 1994; Kleinman, 1988; Luhrmann, 2000). In the context of occupational therapy, a more accurate term is probably *the disability experience*, for it is certainly possible to have a disability, even one that requires therapy, without being ill. Practitioners try to attend both to the disability as a physiological condition and to the meaning this particular condition carries for the person who has the disability (Mattingly, 1998, 2000; Mattingly & Fleming, 1994). If a practitioner knows that a client wants to relearn how to drive, dress independently, eat out at restaurants, or continue to work as an auto mechanic, the practitioner may be able to organize therapeutic tasks that aid the client in carrying out these activities.

However, some goals are far less tangible. This is especially true for goals that concern the client's social world and the connection between functional skills and social relationships. It is artificial to treat only narrowly defined functional skills as though they were unrelated to a client's social world, for a key aspect of the meaning of a condition is how it affects an individual's personal relationships, which is one of the trickier aspects of therapeutic work. By contrast, with such goals as learning how to dress oneself and learning wheelchair mobility, goals and concerns that are connected to family relations are much more difficult to define, and they are certainly likely to be hard to measure. Helping a client to reclaim his identity as a good father to his 5-year-old daughter even though he has a spinal cord injury, for example, is harder to translate into discrete, skill-based goals than is learning how to increase upper body strength or learning how to eat independently. However, learning what family members hope for—what they would like to see happen—is critical to the development of collaborative therapy practices with families. As Cohn, Miller, and Tickle-Degnan (2000) found in their qualitative study of parents of children with sensory modulation disorders, skillful listening to parents' perspectives can generate insights that promote therapy that is meaningful in terms of family goals and values.

Family-oriented goals are likely to be tied to outcomes that are diffuse, complex, subtle, and difficult to measure, even when they are deeply significant to the client and family. When a client's goals and concerns are tied to shifting family relationships, these might seem out of professional bounds for the occupational therapy practitioner. Despite the many difficulties in trying to understand a disabling condition as it pertains to a client's role in the family, ignoring this aspect often means being blind to the most significant aspects of the illness (or disability) experience. Ignoring family-oriented goals or the meaning of a disability as it ties to family concerns and family relationships can mean ignoring the person altogether.

There Is Only One Perspective per Family

Although much of the literature on family-centered care presumes that practitioners come to know all members of the family, we have found that often one member of the family, typically a mother or spouse, serves as the primary contact for the practitioner. It is this individual's perspective that practitioners come to know. However, this might be only one of several perspectives held by family members. Practitioners sometimes get to know other family members, but in many settings, the primary contact is the family member who brings the child to therapy or accompanies an adult or parent to therapy. Often, the family member who comes to the therapy session has a complicated culture-brokering role in which the person needs to

both represent home, family, and community life in the clinic world and represent the clinic and institutional world back in home and family life. Such questions as, "So, what happened?" are indicative of the information requests that spouses, significant others, grandparents, and other family members might ask.

Family members may also have quite divergent perspectives on the nature of the problem, priorities for intervention, and meanings of illness and disability in daily life. These within-family differences often generate within-family negotiations and a kind of "partnering up" within family life that will influence family-practitioner partnerships. The dynamics of these multiple perspectives and within-family negotiations will likely change over time and be influenced by changes in illness trajectories, developmental agendas, household configurations, and constellation of household resources and needs. In addition, illness and disability might be only one subplot or drama in family life, competing with other pressing concerns and needs.

Illness and Disability Generate Only Negative Experiences

There has been, and continues to be, an assumption that all the effects of illness and disability on a family are negative. This belief leads to the erroneous conclusion that family reactions to illness and disability are both predictable and shared. In other words, the practitioner might presume to know about the effect of an illness or disability on the family without fully understanding a particular family. These notions get dismissed once one listens to families talk about their experiences. We have been struck by the incredible richness of their stories and the difficulty people have in reducing their complex reactions to a few discrete categories such as stress, grief, or acceptance. Some theorists have also attempted to develop theories based on stages of reactions, but the fixedness of these stages has been criticized (Moses, 1983).

Much of the research that has been conducted that relates to the response of family members to illness or disability has been conducted with parents of children who have special health care needs. Recently, parents and other family members have offered critiques of this body of research (e.g., Lipsky, 1985), citing the failure of researchers to recognize positive outcomes from these experiences. Researchers have tended to measure such predetermined variables as maternal depression and stress. Critics note that personal reports of other effects, including positive changes in family life, have been discounted. Advocates of the family-centered care movement note the failure of many researchers and practitioners to understand the unique features of family adaptation and coping and assert the need for further research that is grounded in the perspectives of family members. Although it is beyond the scope of this chapter to summarize this body of literature, the assumption that the effects of disability are unilateral and negative must be challenged as both simplistic and inadequate.

Practitioners need to seek understanding of the effects of illness and disability on the families of the people who come to them for assistance. These effects will likely change over time, and the perceptions of the relative stress of families will be shaped by other events in the family and the availability of resources. The presumption that the entirety of a family's experience can be summarized as stressful often leads to misunderstandings and lost opportunities to promote any positive aspects and celebrate successes (Lawlor & Cada, 1993; Lawlor & Mattingly, 1998; Mattingly & Lawlor, 2000).

The Professional Is the Expert

Traditionally, Western biomedicine has been concerned with curing people. The notion of the professional as healer is important here. The healer is an expert who can both ascertain what is wrong (assess and diagnose) and identify the correct intervention to cure the ailment (treat) (Biesele & Davis-Floyd, 1996; Davis-Floyd & Sargent, 1997; M. J. Good, 1995). The patient's role has been viewed as a submissive one, offering information as requested, submitting to physical examination, and following the expert's directives for treatment. In this view, health care professionals make people healthy by curing disease. The concern of the professional is largely with the disease rather than with the person who has the disease (the oncologist fighting the cancer cells with radiation, for instance). The patient's personal history, family situation, and work history might be only of peripheral importance in the healer's task of diagnosing and treating the pathologic condition that is causing the illness. Whereas the hope of medicine has been curing or healing, which implies the ability of the health professional to bring a person from a state of illness to some state of "normalcy" or premorbidity, occupational therapy practitioners are rarely in a position to cure anyone. The people they treat may have rich, full lives, but they are usually living these lives with an impairment or chronic condition that cannot be totally eradicated or fixed.

Practices steeped in Western biomedical traditions frequently adopt professional-client relationships that are based on hierarchical models or expert-driven models. The expert model remains prevalent in early childhood practices, despite increasing recognition that elements of this model create barriers to developing collaborative partnerships and understanding family life. The expert model tends to promote dependence within recipients of services, to limit opportunities for families to contribute insights and have their specific concerns and needs addressed, to burden the professional with the unrealistic expectation of always having the expertise to respond to all issues (Cunningham & Davis, 1985), and to organize services in ways that are self-serving to the expert (Howard & Strauss, 1975).

Practitioners know that therapy will be successful only if their clients (and often the key family caregivers as well) become motivated to work hard at it. But even as

active participants, the clients and family members are often assigned a role as recipients of the instructions offered by occupational therapy practitioners and other rehabilitation experts. While these "active recipients" are sometimes offered a range of choices of goals or preferred activities and practitioners often try to accommodate therapeutic goals into the life of the client or family, practitioners still tend to equate good patients and good families with compliant ones. Thus, a quite typical scenario is for the practitioner to assign homework for the client to do between therapy sessions. When family members are involved in therapy, they are assigned roles as facilitators of the home therapy program. Even though there is nothing necessarily wrong with this kind of collaborative relationship between practitioner and family, it carries some dangers, especially when practitioners are unaware of their power to shift family dynamics and family relationships by pressing family caregivers to become responsible for therapeutic gains. One critical danger is that both practitioners and family members might unconsciously begin to presume that the family's primary role is as a kind of adjunct practitioner.

It is not surprising that reliance on expert models fosters relationships between practitioners and family members that incorporate compliance and coercion strategies. This leads to considerable confusion about whether the "story" is one of collaboration, coercion, or compliance (Lawlor & Mattingly, 1998). The issue is not merely a semantics problem. Each approach to working relationships creates distinctly different experiences for all parties. Practitioner judgments that a person is noncompliant or, in the terms used by family members, "bad parent," "bad daughter," and the like, divert energies away from more reflective analysis or direct attempts to understand alternative perspectives (Trostle, 1988). Comments such as "they are just in denial" often indicate a breach in understanding, a dismissal of family or personal perspectives. Families typically have tremendous expertise and knowledge related to their family members, family life, the illness or disability of their family member, and the ways in which treatment recommendations can most likely be implemented in the home. As Bedell, Cohn, and Dumas (2005) note, parents are well situated to promote and support their child's development in home and community life and able to modify or develop effective strategies.

FAMILY EXPERIENCES AND OCCUPATIONAL THERAPY PRACTICE

We have spent many hours watching occupational therapy practices, primarily with children. In addition, we have interviewed many parents and other family members and practitioners. These data have been gathered as part of a longitudinal, urban, ethnographic research project currently entitled *Boundary Crossings: Re-Situating Cultural Competence.* We have been following a cohort of African American children with illnesses and/or disabilities, their primary caregivers, family members, and the practitioners who serve them for approximately 10 years. This is a multifaceted study that includes analysis of meanings of illness and disability in family and clinical worlds; cross-cultural communication in health care encounters; health care practices including occupational therapy; health disparities; processes of "partnering up" and how illness and disability, family life, health care, and development are interrelated (Lawlor, 2003; Lawlor, 2004; Mattingly, 2006). The conceptual framework for the study draws heavily on narrative, interpretive, and phenomenological approaches to understanding human experience.

One of our most striking discoveries is the way in which seemingly casual conversation, brief moments of social engagement, attention to connectedness, and shared moments in the course of therapy sessions can deeply affect the experiences of family members and practitioners and, perhaps most important, the outcomes of therapy. These moments can be quite subtle and appear to be a kind of backdrop to the real work in therapy time or in health care encounters. Their seemingly mundane nature can belie their impact. As is illustrated below, there are also times of heightened engagement in which there is intensity around the learning or insights to understanding that are unfolding. There are, of course, other kinds of moments in family-centered care that are also consequential and appear to be marked by conflict, tension, drama, or highly charged emotion. As Laderman and Roseman (1996) remind us, "Medical encounters, no matter how mundane are dramatic events" (p.1).

In the following passages, we provide examples of family experiences related to illness and disability and their interactions with practitioners, including occupational therapists. Occupational therapists have shared many stories that relate to how they or their practice has been influenced by their experiences with families. We will begin by returning to the quote that was used to introduce this chapter. In that quote, this mother shared her strategy for ensuring that her family, including extended members, was knowledgeable about her child's therapy program and the clinical world in which therapy takes place. The following passages, excerpted from interviews with the occupational therapist, provide insights into her experiences related to meeting this family and her deep appreciation for lessons learned through this partnership. The occupational therapist credits this mother, whom we will call Leslie, with helping her to learn how to engage with Leslie's daughter, a toddler, who initially would not let the therapist come near her to work with her. As the following quote reveals, this successful partnership began with a rather precarious start:

> And it, it was just such a nice relationship, building of a relationship and then to come back and have her do her therapy with me was a really nice thing. But the

first, um, four months of therapy I couldn't touch her. And that was interesting. I think that almost was successful, because I had to work through Leslie. Leslie did all the therapy and I sort of sat . . . It was really funny [laughter]. I wish we could have some videotape, this was so funny. In the room I would sit in the corner. I had . . . I even couldn't approach her (the child) or she would start to cry. And I would sit a certain distance, which got closer and closer each session and I would direct Leslie what to do. And I think that that taught her so much about what she needed to do and gave her that physical, um, experience that just doing something with her daughter and knowing what it was, what the goals were, rather than sitting back and watching it. That might have been . . . I don't know. 'Cause I just see her as so successful with that and I wonder sometimes if that wasn't part of it. . . . 'Cause she had to, to do her daughter's therapy [laughter]. I, I couldn't. I couldn't get . . . you know. Then finally, and it was Leslie's idea and my idea, too, to bring her other children in because we couldn't get her to move. She wouldn't . . . she was terrified . . . climb up in things or any normal things that would . . . a normal child would explore. She was terrified. So when you see her today, it's like not the same. It was really, really interesting.

At another time, the therapist elaborated on what she had learned from this mother:

And so she taught me a lot about that. And she also— what happens when you work with a mother like that, they, they teach you about the power of negotiation and respecting an individual's rights. Because sometimes as a therapist, when the therapist doesn't have children, I can take more of the teacherly role and put my foot down and push through. And, and I can do that. And as a mother, I don't think that works so much in a household. You just get confrontation. You don't have that kind of power over your kids like a teacher. And she has the most incredible way of negotiating with the personality and she actually taught me how to do that with her daughter. So if I, there were situations where I would kinda be more teacherly and put my foot down and this is the rules and here we go. And Leslie would sort of pull me into a more productive understanding of how she raises her kids and that was really helpful.

The therapist, whom we will call Megan, further clarifies how knowledge about family life facilitates the therapeutic process. Leslie's strategy to bring family members into the therapy world not only enabled the family members to understand more about therapy, but also provided Megan with information that helped her to picture possibilities of family life. Megan also skillfully incorporated stories into therapy conversations that further illuminated life outside the clinic world. In one interview, she commented:

but it's not like in Leslie's case where you just get this just fabulous, you know, understanding of what's going on here. And this sort of communication and commitment and feedback about what's happening there in this other world. Like I have such a knowledge of what's happening in Leslie's world. I mean, I feel like I almost have pictures of their family life and I imagine, you know, she'll tell me a story about the Christmas tree and how Kylie's (the child), you know, she's making her put ornaments in this one section high up because then she has to use her arm in that way. And I can just see the family and I, I. . . .

As part of our research, we are trying to understand more about how practitioners and families do come to know and understand enough about each other to effectively partner up and what attributes influence partnerships. Leslie shares her perspective as follows:

It has nothing whatsoever to do with how much schooling you've had. It's just all from your life experience. And that makes a difference. Because I think my experience that I had with Megan as far as us having to communicate with one another. . . . I don't know a lot—I don't know and I didn't know an awful lot about her personal life. Okay, but I knew enough to know that whatever has happened to her in her life has either made her stronger, or, I don't know if that's what I'm looking for—it gave her a sense of caring about people. Whether it was something that really bad, that she said, Okay I'm not gonna be like that, or something that was really good because she was brought up in a nurturing environment, it just made her personality care. And, and that made a big difference. 'Cause that's what she brought to the table. You know? And, my strong sense of family, and 'course, that's my baby we're talking about, you know. And you have those two, us two bringing back to the table . . . when we sit down to discuss what is best for a child. I think that made a big difference. If—if Megan would have been more of just all business, keep it very technical . . . you know, I think the outcome would have been different. And I probably would have told somebody, I don't want her to be my therapist for my baby. You know, I mean 'cause I wouldn't have felt that, that nurturing that's within her. That's needed as far as I'm concerned, to deal with every child, not just mine. But, oh it's, oh, that is so great!

We now want to just briefly describe a portion of an occupational session that illustrates the often subtle but highly effective participation of family members in therapy sessions. The moment that we describe in the Case Study

occurred partway through a session in which an occupational therapist was working with a young boy with a brachial plexus injury. The activity that she planned provided an opportunity to evaluate his sensation, fine motor abilities, and bilateral coordination. This vignette shows the narrative structuring of therapy sessions and the ways in which family members can contribute through both co-narration and their participation as social actors in the therapy scene (Lawlor, 2003; Mattingly, 1998). Even though we are describing only several minutes within a therapy session here, we are excerpting key aspects. Therapy time, particularly sessions with heightened engagement and family participation, is too rich and too complex to provide all the detail and description.

It is always a bit difficult in written text to convey social action among engaged social actors. In the brief passages in the Case Study, we have attempted to evoke the kinds of animation, attunement, engagement, enjoyment, and joint

---

CASE STUDY: *The Magic Box*

The therapist, whom we will call Georgia, announces a guessing game and presents a rather elaborately decorated box, approximately 9 inches square and 12 inches tall. Micah, who is approximately four years old, his brother Damian, who is several years older, and his mother, Sheana, are all present, along with one of the authors, who is videotaping. Sheana, who is sitting off to the side, says, "Oooh," with dramatic intonation. Georgia further proclaims that it is a "magic box." The two brothers join her in a fairly tight circle on the floor mat. Georgia instructs Micah that he must reach into the box without peeking and find things (these things are small objects that are buried among beans). By touching his left arm, she cues him that this is the arm she wants him to use. (Micah's brachial plexus injury is on his left side.) "See if you can find anything. Move your arm in there. I'll tell you when you have something. No. [whispers] It's a secret box. No, you cannot peek. It's a secret. Find anything in there?" Micah has tried to look under the lid of the box as an adaptive strategy, as he is apparently having trouble feeling the objects buried in the beans. Micah whines a bit in frustration and slips his right hand into the box and quickly retrieves an object. Georgia says, "No, no this hand may not . . . ," and his mother says, "Only lefty can, Micah," thus supporting the therapist's agenda that he use his left arm. Georgia takes the retrieved object and places it in Micah's left hand. She then asks him to show and give the object to his brother, thus smoothly incorporating Micah's older brother into this therapy activity that clearly has potential for further intrigue.

The activity unfolds with continued skillful co-narration and participation of Sheana and Damian. The brothers are highly engaged, and Damian at times seems to scaffold for his brother, thus heightening Micah's potential for success. For example, as Micah reaches into the box, Damian comments, "They might be all the way down," thus facilitating Micah's attempts to move deeper into the box. Sheana, at times, skillfully co-manages the session, seemingly vigilant that Damian does not take over or become too involved, thus disrupting Micah's session, or become disengaged in a way that limits his ability to support the therapeutic activity. For example, she calls out Damian's name when she wants him to pull back a bit or, conversely, to pay more attention.

The action that all four of these actors produce is almost seamless, almost choreographed in its fluidity, but also obviously spontaneous and organized in the flow of therapy. The work that the mother, brother, and therapist do to help make this session so effective is not merely related to promoting the desired behavior, though this is important. Both mother and brother skillfully use changes in tone of voice to support Micah's efforts. The transcript of the session is peppered with comments such as "You did it!" and "Oooh," a kind of quieter admiration. They also seem to be heightening the engagement in the doing, making the "guessing game" more appealing, more dramatic. For example, Damian becomes a kind of announcer about the characters that are retrieved from the box. What seemed initially to be a box of farm animals becomes a box with oddities such that Mickey Mouse, lions, and gorillas appear with considerable puzzlement and humor. As Damian comments when Mickey is found, "What's he doing here?"

At other times in this session, Damian was given many of the same tasks as his brother, such as swinging on the trapeze or picking up the beans that had been strewn on the floor while Micah was digging in the "magic box." Damian's inclusion not only helped to make the session more fun, but also provided many opportunities for reciprocity, turn taking, and sharing between these two brothers. Sheana's careful attention to the session and her sons' behaviors, as well as her skillful co-narration, further added to the perception that this was a family event.

Near the end of the activity, Sheana comments, "It's a very cute thing." Georgia responds with both a smile and the comment "It's something you really could enjoy at home." This is a replay of a conversation that occurred partway through the game when Damian had said, "Let's take it home" in the midst of his enjoyment, after his mother's comment "That's a cute little idea—I like that." A brief exchange follows about whether beans or rice would be better. Interspersed throughout this activity had been comments from Georgia related to the ways in which this was a therapeutic activity for Micah.

coordination that marked these moments. These family members and this therapist created a therapeutic experience that addressed Micah's challenging clinical needs while affording an opportunity for engaging moments. These moments were engaging enough that this family was actively designing ways to replicate the experience at home, to recreate this event in the clinic as a family experience at home.

CONCLUSION

In this chapter, we highlighted many of the challenges that are involved in attempting to respond to the needs of clients and their families. Challenges are coupled with opportunities. As practitioners discover ways of getting to know families and understanding their perspectives, opportunities emerge for practitioners to construct richer, more meaningful experiences. The more meaningful the experience is, the more likely it is that treatment will be efficacious.

We have found that discussions of opportunities must be tempered with specific cautions. Approaches to getting to know families must be noninvasive, sensitive, nonjudgmental, and respectful of the parameters for privacy and disclosure that individuals indicate. Understanding a perspective does not presume that as an occupational therapy practitioner, you are responsible for intervening in every dimension of that perspective. Family-centered care is implemented most effectively in situations in which interdisciplinary efforts are well coordinated and effectively communicated. In situations in which practitioners are working in relative isolation, caution must be exercised to ensure that they are practicing within the bounds of their expertise and appropriately facilitating access to other resources as needed.

One of the greatest challenges for practitioners is to understand how their own lived experience shapes their interactions with family members in the course of providing services. Conceptual models of practice and theory regarding family systems and human development, ethics, and public and institutional policies all contribute to our framework for family-centered interventions. However, practitioners, as the instruments for intervention, bring their own selves and their cultural views of families into clinical interactions.

We intuitively recognize that such things as our ethnicity, nationality, geographical home, and perhaps even religion provide us with powerful cultural worlds. These aspects of our background help to make us who we are, culturally speaking. We are often not fully aware that our profession and our family also offer cultural worlds that shape some of our deepest assumptions, beliefs, and values. This chapter concerns a kind of cultural intersection between the practitioner (acting as a member of a professional culture) and a client (acting as a member of a family culture). Practitioners, of course, have families, and clients often have professions. However, when practitioners and clients meet during occupational therapy intervention, the practitioner's professional and institutional cultures are particularly significant in shaping how the practitioner defines good intervention and a good professional-client relationship.

Occupational therapy practitioners come to their profession with life experiences of being a member of a family. This lived experience of growing up in a family significantly shapes who we are as practitioners, particularly in situations in which practitioners are getting to know a family and seeking to understand their needs, priorities, values, hopes, and resources. These assumptions about family life tend to be quite tacit, and we are often not aware of their influence unless we actively reflect on our actions. Guided reflection through mentorship and supervision, as well as discussions with other team members concerning beliefs about specific families, are essential components of intervention planning and implementation with clients and their families.

ACKNOWLEDGMENTS

PROVOCATIVE QUESTIONS

1. Reflect on the quotations from Leslie and Megan and comment on what surprised you most.
2. What do you think helped to make this relationship work?

3. How do you think your own life and family life experiences might affect how you "partner up" with families?

4. Can you identify any additional problematic assumptions that might influence your collaboration with families?

Contribution of Occupation to Health and Well-Being

CLARE HOCKING

Learning Objectives

After reading this chapter, you will be able to:

1. Explain how health is both a resource supporting participation in occupation and an outcome of participation.
2. Define what is meant by health and how health differs from well-being.
3. Explain health in terms of biological needs, skills, and capacities.
4. Identify physical, mental, and social aspects of well-being and how these might be influenced by a person's physical, social, and attitudinal environment.
5. Discuss the ways in which people's occupations and how those occupations are organized might support or undermine health and well-being.
6. Explain how having an impairment might affect well-being, taking into account present-day occupational experiences, expectations for the future, and the influence of environmental barriers.

> *Jane:* I always make fruit-mince pies at Christmas. I make quite a big deal out of it I guess, because I make my own fruit-mince and put lots of brandy in it. It really is delicious, even if I do say so myself. I'll cook up quite a number when I get going, four or five dozen I suppose. I have a bit of a production line going. When I go and visit my friends, I make up a little package of two or four of them depending on the number of people. It doesn't constitute a present. We're not into Christmas presents, you can spend so much on them it's ridiculous. It's just a little something.
>
> *Brenda:* It works very well.
>
> *Dawn:* I like your idea of it not being a present as such. It's not costly and it doesn't give the receiver a feeling that "Oh, I've got to get you something."

Jane: It does work well. That's what people like to
have and they like my mince pies. They're
eaten on the day, and I have enough left over
for Boxing Day.

(Wright-St. Clair & Hocking,
unpublished data, 2000)

Jane, Brenda, and Dawn agree that Christmas fruit-mince pies are the perfect gift. Jane has the pleasure of savoring the smell of the minced fruit as it matures over several weeks and enjoys the process of efficiently baking all the pies. She knows that her friends appreciate the time and effort she puts into her gift but do not feel obligated to buy something to give her in return. Best of all, because they are fresh and delicious, Jane knows that her pies are eaten straight away. In this ordinary yet thoughtful **occupation**, Jane exercises her skills as a cook, employs her knowledge of the meaning of Christmas, and reinforces relationships that make her world a warm and welcoming place. In return, she receives feedback that her effort, expertise, and friendship are appreciated.

The feelings of competence and social relatedness that Jane experiences through baking and gifting food contribute to her overall sense of **well-being**. Despite her advancing years, Jane continues this annual tradition along with many other occupations she considers important. Although her daily routines and occupational choices are different from those of other times in her life, she is generally satisfied with her life and circumstances. Moreover, when she is fully engaged in and enjoying what she is doing, such as when she is parceling up her fruit-mince pies, Jane experiences a welcome sense of vitality and involvement with friends, family, and her community.

OCCUPATION AND HEALTH

Jane's experience aligns with popular understandings of **health** and well-being. Unlike biomedical views of health, which tend to emphasize the absence of disease (Glanze, 1990), people in Western societies commonly perceive themselves to be physically and mentally healthy when they are able to do the things that are important to them. In fact, people often claim to be in good health despite having quite severe health conditions, restricted life circumstances, and clearly apparent limitations in **functioning** (World Health Organization [WHO], 2001). For example, one woman who declared that she was "very healthy apart from this arthritis" was described by a researcher as a "crippled and housebound woman of 61" (Blaxter, 1990, p. 22). People generally equate their health with appearance, physical fitness, energy levels, psychosocial well-being, social relationships, and being able to carry out their normal round of occupations (Blaxter, 1990). It is this occupational view of health that is the focus of this discussion.

FIGURE 5.1   Bruce and John at work drafting sheep.

The first point to note is that being in good health clearly supports the ability to do normal, day-to-day occupations. That is, it helps if people are sufficiently fit, strong, and flexible; able to focus their thoughts and attention; and not too fatigued to do what needs to be done. For example, Bruce and John (Figure 5.1) rely on being healthy to complete tasks around the farm. It also helps if their efforts are not unduly hampered by pain, deformity, breathlessness, malnutrition, confusion, despair, or the apathy that comes of boredom or hopelessness. In this sense, health is a resource, albeit one that many people take for granted. One illustration of treating health as a resource for occupation is the response to illness. For many people, being sick is a legitimate reason not to do the things they usually do. Illness often means being released from responsibilities and that others will do things on the sick person's behalf. Thus, mothers cook chicken soup or the cultural equivalent for their sick family members, and workmates take on extra tasks to ensure that essential aspects of the ill person's job are completed on time.

Needs, Skills, and Capacities

While health facilitates **participation**, the opposite is also true: Participation in occupation contributes to good health. At the level of individual and species survival, as Wilcock (1993) has cogently argued, occupation is essential because the basic **biological needs** for sustenance, self-care, shelter, and safety are met through the things people do. In meeting these needs and through other occupations of daily life, people develop "skills, social structures and technology aimed at superiority over predators and the environment" (Wilcock, 1993, p. 20). These skills include, for example, growing and cooking nutritious food and constructing warm clothing and dry houses. Also important, though not always achieved, is the skill of living peacefully with neighbors. Depending on the circumstances, many other skills are also relevant to health. Reading and writing, for example, are important means of conveying information

relevant to sustaining health and seeking health care in Western societies but may be less relevant in other places. It is also important to note that not everyone needs all the skills that are relevant to survival. Rather, health depends on being part of a family or community of people who together have the skills necessary to survive, and perhaps to flourish, as well as access to the resources to put their skills to use.

Meeting survival needs and becoming skilled are not sufficient to ensure good health; of equal importance is the contribution that occupation makes to developing and exercising personal **capacities** (Wilcock, 1993, 1995). These capacities spring from the biological characteristics shared by all humans: walking upright, opposing thumb and fingers to grasp objects, learning to speak, and so on. People have the capacity to, among other things, carry loads, design new tools and find novel uses for old ones, understand the workings of the universe, accumulate and pass on knowledge, predict what might happen and prepare for the future, form relationships, and express themselves artistically and spiritually. People also have the capacity to play, as Jamie shows us, caught in the moment of throwing a petanque ball (Figure 5.2).

Each person's capacities reflect this human potential, via his or her genetic inheritance, brought into being through the developmental process and a unique life history of occupational opportunities, preferences, and choices. On the basis of their history of doing things and expectations of what they might do in the future, people are generally aware of the capacities they have: whether they are better at sport, art, or music; whether they find schoolwork or practical tasks more congenial; and whether they prefer solitary occupations or mixing socially.

The capacities that are most often cited in relation to being healthy are those relating to physical performance. For example the estimated 20 million to 30 million Americans who regularly run say that they do so to enhance their physical fitness, that is, their capacity for intense physical activity, as well as for the benefits it bestows on weight control and feeling good (Primeau, 1996). Not everyone likes to run, however, and many people do not regularly engage in other physically demanding occupations such as gardening, swimming, riding a bicycle, playing a sport, or cleaning. In short, people who do not exercise are not maintaining the capacity to exert themselves physically. The consequences are potentially serious. As well as not being able to sustain physical exertion, should they need to, people who do not engage in sufficient physical exercise have increased risk of cardiovascular disease and cancer (Wallis, Miranda, & Park, 2005). Lack of exercise is also associated with the looming crisis of childhood obesity (see the case study). For those who do not exercise in other ways, walking reasonably quickly for at least 30 minutes a day, five days a week, is considered the minimum requirement to maintain health (Wallis, Miranda, & Park, 2005). Estimates of the number of people who achieve this level of activity vary. Only 6% of Norwegians over 65 years of age

FIGURE 5.2 Jamie intent on playing petanque.

meet this exercise guideline (Loland, 2004). In the United States, 22.4% of adults engage in vigorous physical activity five times a week; the percent by age range decreases from 31.7% for people age 18–24 to 6.2% for people 75 years and older (Centers for Disease Control and Prevention [CDC], 2005a). These statistics indicate that many people's lifestyle does not support optimal health.

Although less emphasized in the literature, exercising mental and social capacities in order to maintain cognitive functioning, psychological health, and positive social networks is also important. Indeed, participating in occupations can generate benefits that cross physical, mental, and social aspects of health. For instance, a large-scale study of older Americans showed that social and productive occupations decreased their risk of mortality as much as physical activities did (Glass, de Leon, Marottoli, & Berkman, 1999). Likewise, older people in residential care in Britain live longer and are less likely to be depressed if they are aware of opportunities to be occupied and enjoy the things

they do (Mozley, 2001). Similarly, the more older Americans garden, dance, play golf or bowl, swim, cycle or jog, or walk for exercise, the better their cognitive functioning is likely to be. Participating in these occupations seems to reduce the likelihood of depression and to strengthen social networks (Vance, Wadley, Ball, Roenker, & Rizzo, 2005).

Developing Skills and Exercising Capacities

What stimulates people to engage in occupations that enhance their chances of survival, develop skills, and exercise capacities is much debated. One suggestion, first advanced by Wilcock in 1993, is that humans experience biological needs that stimulate occupation, which in turn promotes health. These needs relate, first, to correcting threats to our physiological state, such as being excessively hot or cold or feeling hungry or thirsty. The discomfort of these sensations stimulates us to action: to find some shade, put on more clothing, or seek out food or drink. (See Figure 5.3.)

The second set of needs is protective and preventive, such as the need to develop skills and exercise capacities. These are experienced as a surge of energy that propels us to acquire and practice the skills required to solve problems and plan, interact with others, do whatever generates our livelihood, and so on. In so doing, at least before technology removed many of the physical demands of earlier lifestyles, people exercised their capacity for physical, mental, and social functioning. The third and final set of needs prompts and rewards engagement in occupation. Meeting these needs gives a sense of purpose, satisfaction, and fulfillment. More typically associated with higher levels of health and well-being, these concepts are addressed later in the discussion.

HEALTH AND WELL-BEING

While no definitive description of well-being exists, it is generally understood to be a person's subjective perception of his or her health. In Western societies, in which individualistic values prevail, well-being is commonly associated with concepts such as self-esteem, happiness, a sense of

belonging, and personal growth and encompasses people's feelings about their physical, mental, and social health (Wilcock, 1998). The cultures of indigenous populations frequently also include notions of spiritual well-being, community spirit, and connection to the land (Aguis, 1993; Durie, 1994). Taking an ecological perspective, Wilcock (1998) has suggested that people's well-being is inextricably bound to the health of local and global ecosystems.

Acknowledging that health and well-being are affected by factors outside an individual suggests that something can be learned about individuals' health and well-being by examining relevant measures of population health. Accordingly, when considered in relation to mortality statistics, well-being seems to relate to employment, prosperity, and ethnicity, since people who are employed, those with higher incomes, and members of the dominant ethnic group in a society have lower incidences of most chronic diseases and better health care outcomes (CDC, 2005b; Ministry of Health Manatū Hauora, 2005). Moreover, their children are more likely to survive (Whitehead, 1988).

This is not to say that well-being is incompatible with disease and injury. Indeed, even people with a terminal illness can put that fact aside, at least for a while, and thoroughly enjoy themselves (Hasselkus, 2002). It does acknowledge, however, the additional burden of having a health condition, particularly if the person's physical, social, or attitudinal context is less than supportive of participation in the normal range of occupations others enjoy (WHO, 2001). Examples of such circumstances include inaccessible buildings, poverty and high levels of unemployment, and the stigma attached to conditions such as AIDS, leprosy, and mental illness. Facing these barriers, particularly when they persist, might well challenge perceptions of well-being.

OCCUPATION AND WELL-BEING

In the previous section, well-being was defined as the subjective experience of health or people's feelings about their health. From an occupational perspective, feelings of well-being arise from the things people do that provide a sense of vitality, purpose, satisfaction, or fulfillment. Occu-

FIGURE 5.3 Biological hierarchy of need for occupation. (From Wilcock, 1993.)

pational well-being also relates to the things people envision doing in the future. Well-being is expressed in terms of feeling on top of the world; feeling nourished, contented, transformed, at peace, strong, interested, and fully alive; or experiencing intense concentration (Wilcock, 1998). Such views are largely in keeping with the Ottawa Charter, which asserts that to attain complete well-being, "an individual or group must be able to identify and to realize aspirations, satisfy needs, and cope with the environment" (WHO, 1986, p. 1). As was discussed earlier, the mechanism by which people achieve these things is through occupation.

Not surprisingly, however, attempts to equate well-being with frequency or extent of participation in valued occupations have been largely unsuccessful (see for example, Christiansen, 1996; Stanley, 1995). This finding supports the notion that well-being relates more to the quality or intensity of the experience itself (Csikszentmihalyi, 1993; Persson, Eklund, & Isacsson, 1999). Examples of people experiencing a sense of well-being through occupation abound. Within the occupational science literature, they include the claims that dance is a transformative occupation that can awaken people to their spiritual essence (Graham, 2002) and that cake decorating both reduces stress and gives rise to immense satisfaction. Moreover, recipients interpret the time put into decorating their cake as a gift of love, which implies a positive impact on their sense of well-being (Scheerer, Cahill, Kirby, & Lane, 2004). Similarly, quilting unlocks creativity, even as women work within the structure of traditional quilting patterns, and for some becomes an all-consuming pursuit. In addition, it fosters learning and sharing and feeds curiosity (Dickie, 2003, 2004). Equally, women who attend book clubs in Australia relish the opportunity to "let their hair down" (Howie, 2003, p. 135) and freely express ideas and feelings.

As is suggested by the recipients of decorated cakes, occupations also afford opportunities to influence others' well-being. One example is the older women in Northern Thailand who cook kha nom jok, a sweet or savory snack, for the New Year celebration (Figure 5.4). The literal meaning of the name of this dish is "togetherness" or "wrapped together." By willingly undertaking the task of preparing this dish and ensuring that it is of the very best quality, these women hope to confer this epitome of social well-being on their family (Hocking, Wright-St. Clair, & Bunrayong, 2002). In addition, by sharing the food they have cooked with friends and neighbors, older Thai women enact traditional values of making a good and generous society (Wright-St. Clair, Bunrayong, Vittayakorn, Rattakorn, & Hocking, 2004).

Half a world away, in a suburb in North London, housewives strive to achieve more individually targeted improvements in well-being. This means purchasing healthier foods than their children might select for themselves, choosing better-quality clothing than their children prefer, and occasionally buying treats for themselves and other family members (Miller, 1998). Of course, a single occupation can influence well-being in multiple ways. For

FIGURE 5.4   Wrapping kha nom jok ingredients together symbolizes bringing people together.

instance, while cooking dinner for the family can be a pleasant experience in itself, consuming it together around the table might provide sustenance and create a sense of connection with others. Depending on the menu, it might also serve as a reward, a family celebration, and a potent symbol of affection (De Vault, 1991). Although most of these examples relate to women's occupations, there is no reason to think that men do not experience similar benefits from masculine pursuits. Trevor, for example, willingly climbed a ladder to lend a hand, fixing the guttering on the shower block at the campground where he was holidaying (Figure 5.5).

TIME USE AND WELL-BEING

As well as the contribution specific occupations make to well-being, the impact of overall patterns of occupations is important. One trend that has been widely noted is the increasing tempo of modern lifestyles. This phenomenon, in which people rush from one occupation to the next, is associated with high workloads, limited access to leisure time pursuits, and increasing levels of stress and stress-related illness (Zuzanek, 1998). Perhaps more significant, because they do not have time to reflect on and experience meaning in living, people are channeled toward culturally constructed occupations such as shopping at the mall rather than pastimes they might find more absorbing and rewarding (Clark, 1997). Such lifestyles appear incompatible with
FIGURE 5.5   Trevor fixing the guttering at the campground.

high-level well-being. In response to such concerns, Cusick (1990) suggested categorizing the routine occupations that are undertaken in a typical week as enjoyable, boring, disliked, or performed automatically, in hopes that people might understand the relationship between the things they do and their lack of well-being.

Three further insights in relation to occupation and the ways in which people use time are also pertinent here. The first is the link Erlandsson (2003) established between time use and well-being. Her study traced 100 Swedish women's daily occupations, focusing particularly on transitions from one activity to another. It showed that highly complex patterns of occupation characterized by frequent interruptions and changes of task correlate with lower levels of reported well-being than are found in women with less complex occupational patterns. The second relates to the temporal demands of shift work and the reasons female nurses who work the night shift sacrifice sleep to fulfill their responsibilities as mothers, caregivers, and home-makers (Gallew & Mu, 2004). The long-term impact of disrupted occupational routines and sleep deprivation once again appear incompatible with well-being. The third consideration in relation to time use is the boredom that results from lack of occupation. Drawing from her study of young offenders, Farnworth (1998) proposed that boredom

is perhaps "endemic in Western industrialized nations" (p. 145). The short- and long-term impact of boredom on health and well-being is unknown, in part because boredom itself is poorly understood. Nonetheless, workplace boredom has been associated with low morale, depression, and engagement in destructive and unauthorized activities (Long, 2004).

Over a longer time span, occupational scientists and others have suggested, people become what they do. Two studies in particular lend support to a relationship between what people do over their lifetime and well-being. They first proposed the concept of occupational persona, which is described as an aspect of self that "is shaped, and to some extent reinvented" through engagement in occupation (Whiteford & Wicks, 2000, p. 48). Of note in the context of this discussion are several themes used to depict these personas, variously described as having a passion, seizing opportunities, creating fun, feeling proud and satisfied, and creating a better world, which echo definitions of well-being.

The second study addressed the occupational potential that each person realizes, in the context of personal, historical, sociocultural, and political influences (Wicks, 2001, 2005). Looking back over a lifetime, the person might or might not derive a sense of well-being depending on the person's evaluation of his or her choices and accomplishments and the person's restrictions and regrets. As this discussion implies, it is the evaluation of their choices and accomplishments that influences the extent to which people experience well-being. As Casey (1995) observed, some "experiences restrict opportunities for personal control, skill-use and intimacy" (p. 81). If, in addition, opportunities for personal development are few and use of "initiative, thought and independent judgment . . . [is not welcomed, then] what people do in their work directly affects their cognitive functioning, their values, their conceptions of self, and their orientations to the world around them" (p. 82). Although Casey's focus was on people's employment experiences, it is conceivable that other people experience similar restrictions in other realms of life.

OCCUPATION, IMPAIRMENT, AND WELL-BEING

It is well known that occupation can harm people. Indeed, to shock the nation into legislative reform, nineteenth century social reformers graphically exposed the ways in which working in Britain's coal mines stunted, maimed, and sickened workers (Wilcock, 2001). Although safety standards, working hours, and the grueling physical demands of previous decades have substantially improved (Guber, 1995), the risks that workplace occupations pose to health and well-being remain a focus for unions and governments alike. Less attention has been paid to the risks that nonwork occupations may pose and people's experience

of participation in day-to-day occupations when they have an **impairment**.

The term *impairment*, in everyday language, suggests an injury, flaw, or imperfection or that some harm has occurred. In this context, a more precise meaning is implied, consistent with the World Health Organization's *International Classification of Functioning, Disability and Health* (2001). That is, an impairment is any problem with normal psychological or physiological function or with a body structure such as a joint or organ. In this sense, health conditions may cause impairments, for example, loss of power in an arm after a stroke. In addition, impairments may put people at risk of a health condition, such as a person who becomes depressed when denied access to work because of a cognitive impairment.

Although few studies have explored the relationship between occupation, impairment, and well-being, a small body of occupationally focused studies suggests that the presence of impairment may or may not undermine well-being. One determining factor seems to be the effect impairment has on participation in occupation. For instance, older people who were admitted to the hospital after an acute health episode discovered by trying to do things how their impairments had changed their capacity for occupation. This knowledge underscored the seriousness of their condition. However, as their health stabilized and they mastered new ways of completing tasks, they grew more hopeful and sought opportunities to test and strengthen their returning function (Gooder, 2001). Theirs was an experience of return to well-being. Similarly, while men with dyspraxia struggle to complete once familiar tasks such as putting on socks and shoes or making a hot drink, their small successes and signs of improvement elicited expressions of triumph and renewed hopefulness for the future (Blijlevens, 2005).

In contrast, adults with a rapidly advancing neurological disease experienced their impairments as losses, evidencing not only diminishing occupational capacity but also loss of valued aspects of identity, inability to access occupational settings that gave variety to life, and an inevitable decline toward dependency and death (Brott, 2004; Hocking, Brott, & Paddy, 2006). Expressions of courage, humor, gratitude for remaining abilities, and appreciation for the support received from family and health care workers were overshadowed by fatigue, frustration, distress over loss of the future they had envisaged, and fear of becoming a burden. Each of these has an occupational component:

◆ Fatigue from basic self-care tasks
◆ Frustration over declining occupational capacity, barriers to valued occupations, and long hours that were no longer filled with productive activity
◆ Regret for occupations they had looked forward to and would now not achieve, such as holding a grandchild

As their health declined, their sense of well-being was under constant threat.

Considered together, these studies suggest that whether impairments detract from well-being is influenced as much by a person's expectations for the future as by his or her present-day experiences.

Despite enjoying what they do and being hopeful for the future, however, people who have an impairment can face external barriers that undermine well-being. Roulstone (1998) found that 90% of people with a disability who used enabling technologies at work identified ways in which technology directly benefited them. Nonetheless, they reported continued barriers to employment, including problems with "limited workplace access, inadequate training, under use and misuse of new technology, and the continued presence of disabling attitudes" (p. 125). They reported being made to feel like an inferior worker, instances of physical impairment being equated with low intellect, and a general expectation that they "should feel lucky that their employers have the heart to employ them" (p. 115). In addition, they faced begrudging attitudes and resentment toward the provision of technology when they were given technology that was not available to able-bodied workers.

In addition to these workplace issues, people with an impairment that affects occupational performance find that societal factors make participation in work more difficult. The women in Jakobsen's (2004) study, for instance, battled with the lack of recognition of the additional physical and psychological rigors of self-care and domestic tasks for those who are not able-bodied. They also reported difficulty managing appointments with health care workers, home help, wheelchair maintenance personnel, and care assistants, who were available only during work hours. Despite being highly motivated to work and deriving all the benefits of employment that others report, all three women found participation in work too strenuous and resigned their positions. In sum, Roulstone's and Jakobsen's studies suggest that the benefits most people derive from employment might not be sufficient to support well-being in the face of unavoidable barriers in the physical, social, and attitudinal environment.

STRUCTURING OCCUPATION TO ENHANCE WELL-BEING

Even if workplace experiences do not always support well-being, people are surprisingly resourceful in structuring their occupations to support and enhance well-being. For instance, immigrant women, recently arrived in New Zealand from India, adopted three key strategies to help them settle in and feel at home. They consciously preserved some occupations from their home country, stuck to familiar routes and venues for repeat occupations such as grocery shopping, and asked for advice about how things are done in their adopted country (Nayar, 2005).

Similarly, as people recovered from mental illness, they reported progressing from a disintegrated experience

CASE STUDY: *Do or Die*

Dennis is 11 years old and lives in a low-socioeconomic-level suburb of a large city in Sweden. He likes to watch television and, as he has grown older, has started to play computer games and to surf the Internet. On average, he spends around 3 hours a day on the computer (Magnusson, Hulthén, & Kjellgren, 2005). If he lived in Israel, that figure might have been as high as $4\frac{1}{2}$ or 5 hours per day (Nemet et al., 2005). While he watches, plays games, or surfs, Dennis likes to have a glass of fruit juice or lemonade. Like the other 30% of children in his suburb who are overweight or obese, he also tends to skip breakfast. Despite the health risks adults associate with low levels of physical activity, high calorie intake, and starting the day without food, Dennis does not believe that his lifestyle has any effect on his health (Magnusson, Hulthén, & Kjellgren, 2005).

Is Obesity So Bad?

Were he located in New Zealand, the health risks Dennis faces would be well recognized. If he were one of the 26% of boys of Pacific Island heritage aged 7–14 years who are obese, he would face well-documented risks of joining those already presenting with type II diabetes (Ministry of Health, 2003). In a few years, he might well contribute to the skyrocketing figures for life-threatening cardiovascular disease and, rather than following the trend of increasing longevity recorded over recent decades, have a substantially reduced life expectancy.

What If Dennis Were American?

If he were American, we might suspect that Dennis's obesity was associated with some well-known features of the urban landscape. As reported in *Time* magazine, most American cities were designed for automobiles (Wallis, Miranda, & Park, 2005). That means that most suburbs lack sidewalks and bike paths. No wonder that between 1991 and 1995, walking anywhere became 40% less likely and the chances of walking to school were reduced by 60%. Indeed by 2001, the statistics report, walking and riding a bicycle accounted for only 13% of trips to school. All this suggests that even if Dennis lived less than a mile from school, he would not have walked.

   In fact, locating Dennis in the United States rather than in Sweden might have meant a lifestyle with very little physical effort, especially given that many schools with tight budgets have trimmed physical education classes from the curriculum. Furthermore, his parents might be among the 65% of Americans who would like to exercise more but do not have enough time, find exercise boring (28%), or do not have access to a convenient place to exercise (24%). One advantage of being in the United States, however, is that Dennis would be in the midst of a growing awareness that lack of physical exercise might be an even greater threat to health than obesity (Wallis, Miranda, & Park, 2005).

Can Anything Be Done?

Perhaps if he lived in Israel, Dennis might have been one of the 54 obese children recruited to a research group (Nemet et al., 2005). With a little luck and the right attitude, he might have found his way into the active treatment group and been one of 20 participants to complete a three-month exercise program and one-year follow-up. In that case, Dennis would have had the privilege of joining in games led by former members of the national track and field team for two hours each week. To supplement that program, Dennis and his parents would have participated in counseling sessions focusing on food choice and behavior change. That advice would have included cutting his food intake by about 30%. He would also have been encouraged to walk or engage in some other physical exercise for another 30 to 45 minutes a week.

   At follow-up, it is likely that Dennis would have gained less than a kilo in weight, compared to the average 5.2 kilos put on by children in the control group. He would have significantly less body fat and more important, significantly increased activity levels and physical endurance. In addition, he would have cut his TV and video game time by more than an hour a day (Nemet et al., 2005).

Questions and Exercises

- Research results cited in this case study identify calorie intake, physical inactivity, and urban design as factors contributing to childhood obesity and its associated health problems. What other parental, environmental, societal, or legislative factors can you identify as contributing to the problem?
- The program implemented in Israel might or might not be feasible in your context. If you were working with children between 6 and 16 years old, what features of the Israeli program would you hope to replicate and which would you modify?

of doing and being they described as nondoing, through different levels of occupational engagement characterized variously as half-doing, engaged doing, and absorbed doing. This progression enabled their participation in the human and nonhuman world at an intensity they could sustain and that contributed to their reconnection with the environment, structuring of time and space, reintegration of a sense of self, and the opening up of future possibilities in the everyday world (Sutton, 2006).

   At a community level rather than an individual level, an elder of the Windjingare tribe in Australia described how he drew on traditional ideas about socially useful work to help his people break the cycle of welfare dependency, alcoholism, and violence. The venture focused on voca-

tional opportunities in the bush, where young people learned traditional skills and values and built culturally appropriate housing, using their own labor and incorporating bush materials. A key element, in line with long-established practices, was the intention to move between different locations and occupations for the wet and dry seasons (Shaw & Dann, 1999).

CONCLUSION

The things we do meet our biological needs for sustenance and shelter. Occupation keeps us alive. In the longer term, occupation can provide the physical activity, mental stimulation, and social interaction we need to keep our bodies, minds, and communities healthy. In addition, through participation in occupation, we express ourselves, develop skills, experience pleasure and involvement, and achieve the things we believe to be important. In short, we have opportunities for enhanced levels of well-being. Being healthy supports engagement in occupation, and it is often in the process of doing things that we realize how healthy we are and enjoy a heightened sense of well-being.

Equally, occupation can threaten or destroy health. Doing too much, doing too little, and doing things that expose us to risk can all have deleterious effects. It is also important to recognize that it is often through having trouble doing things that we become aware of health issues and the full impact of impairments. Furthermore, physical, social, or attitudinal barriers in the environment can exacerbate the impact of a health condition or impairment, sometimes to the point at which participation in occupation is unsustainable. However, if we carefully structure the things we do, review lifestyle choices, and address barriers to participation, engagement in occupation can improve people's health and well-being.

PROVOCATIVE QUESTIONS

1. Wilcock proposed that people have needs that serve as warnings, protect us, and reward participation in occupation. Why, then, do most people in postindustrial societies fail to get sufficient exercise?
2. If immigrant women, people recovering from mental illness, and community leaders can structure occupations to enhance their own and others' health and well-being without help from an occupational therapist, are occupational therapists necessary?
3. Which of your occupations support your health and well-being? Which threaten them? How could you change your lifestyle or environment to maximize well-being?
4. If you could change one thing in the physical, social, and attitudinal environment of your country to enhance the nation's health and well-being, what would you change? How would the change you propose affect people's occupations?

Culture, Race, Ethnicity, and Other Forms of Human Diversity in Occupational Therapy

6

JULI McGRUDER

> "What sets worlds in motion is the interplay of differences, their attractions and repulsions. Life is plurality, death is uniformity. By suppressing differences and peculiarities, by eliminating different civilizations and cultures, progress weakens life and favors death. The ideal of a single civilization for everyone, implicit in the cult of progress and technique, impoverishes and mutilates us. Every view of the world that becomes extinct, every culture that disappears, diminishes a possibility of life."
>
> —OCTAVIO PAZ (1967)

Learning Objectives

After reading this chapter, you will be able to:

1. Discuss culture in terms of a list of six agreed-on attributes.
2. List and discuss five reasons for occupational therapists to strive for an accurate understanding of culture and other forms of diversity.

3. Distinguish between cultural awareness and cultural sensitivity and examine one's own levels of each.

CULTURE AND OTHER FORMS OF HUMAN DIVERSITY IN OCCUPATIONAL THERAPY

My friend Lizzi grew up in rural Oregon, surrounded by plants and animals. Now an adult, living in the suburbs, Lizzi plants dozens of flower bulbs and "puts up" scores of quarts of fruits and vegetables every year. She even cans foods that she does not eat, such as fish. She has a rambunctious young Labrador retriever, an elderly cat, and a noisy parrot. Lizzi also has tetraplegia, from a C5–6 spinal cord injury, and very compromised hand function. She admits that snapping beans and peeling peaches are laborious and difficult activities for her and that managing the hot water bath for her canned goods has led to so many burns that she now delegates this part of the canning activity to her goddaughter. Still, she would never choose to give up her canning. While she notes that Bijou, the Labrador, could easily tip her wheelchair, she persists in her routine of coming home from a long day of advocacy work to patiently train the young dog.

When I visit Lizzi, I stand in awe of the power of culture to influence occupational choice. If I had Lizzi's physical limitations, I would give up the bit of gardening I do. I would not take on the care routines of three pets or the laborious tasks of canning. Yet Lizzi chooses to reenact with her sisters, nieces, and goddaughters the productive social activity of gathering in the kitchen several times each year to preserve foods, just as her mother and aunts did. She chooses to pass on the cultural tradition of canning the best pickled green beans. This is culture at work. The high value attached to home-processed foodstuffs, the knowledge of recipe contents and processes, the form of the gendered social gathering, and even the idea that vegetable matter steeped in vinegar and salt is delicious have all been culturally transmitted. Because culture underlies occupational choice, it is of central interest to occupational therapy practitioners.

Culture is a notoriously difficult concept to define. A recent dialogue in *American Journal of Occupational Therapy* reviewed definitions of culture, the history of their use by anthropologists, and their current utility for occupational therapy practitioners (Bonder, Martin, & Miracle, 2004; Dickie, 2004). In occupational therapy, *culture* has been defined as learned, shared experience that provides "the individual and the group with effective mechanisms for interacting both with others and with the surrounding environment" (Krefting & Krefting, 1991, p. 102) and as evident in both group patterns and individual variations in occupational behavior (Bonder, Martin, & Miracle, 2004). The American Occupational Therapy Association (AOTA) defines culture as "customs, beliefs,

activity patterns, behavior standards and expectations accepted by the society of which the individual is a member" (2002, p. 623). Frank and colleagues prefer a definition that recognizes the contested status of cultures "as composed of competing discourses and practices within social fields characterized by the unequal distribution of power" (2001, p. 503). Occupational therapy practitioners aim to discover and support clients' agency in making meaning in everyday actions and activities, which necessitates interaction with the cultural worlds into which their clients have been socialized (Mattingly & Beer, 1993).

Culture is just one distinguishing human characteristic, however, and cannot be relied on to explain all kinds of difference. Dyck (1992) cautioned occupational therapy practitioners not to confuse culture and other sources of difference when she wrote:

> A reliance on culture as distinct beliefs, values, and customary practices to explain nonadherence and difficulties in the therapeutic process is misguided. The everyday social and work conditions that shape health experiences and behaviors must also be recognized. These, in turn, are forged within a socioeconomic and political environment. (p. 696)

Dyck (1993) and Fitzgerald (2004) have raised this specific caution in the use of the culture concept in occupational therapy. Their concern is informed by three more general criticisms of conceptualizations of culture: that the concept, misused, has a tendency to essentialize, reify, and mystify human difference. To *essentialize* is to take complex multifaceted phenomena, such as the lifeways, ideas, and all that a group of humans has acquired by learning, and reduce them to a few basic and inherent "essences" that purport to explain this group in totality. Descriptions that essentialize are often ahistorical, and in that way, they distort. To *reify* is to "thing-ify," to take an abstract and to treat it as a fixed and concrete thing with definable boundaries. Treating culture as a thing can promote stereotyping. Reifying culture ignores the interactive nature of humans as creators of culture situated in environments that change. Reifying fails to notice that many humans have incorporated ideas from more than one culture. To *mystify* is to obscure important causes, contributing factors, or results of a phenomenon. For example, when Senator Daniel Patrick Moynihan (1965) referred to the African-American family as a "tangle of pathology," he obscured the economic and political factors that underlay cultural phenomena he was criticizing. Dyck, quoted above, was specifically concerned that differences in seeking and following health care advice noted among Chinese immigrant women in Canada not be misunderstood as cultural when in fact the source of difference was related to economics and work situations. She documented a similar concern related to health promotion research with Indo-Canadian Sikh mothers (Dyck,

1993). Attempts to define or discuss culture should try not to reproduce common errors and fallacies. With that precaution in mind, let's examine a list of agreed-on defining attributes of culture.

WHAT CULTURE IS: AN AGREED-ON LIST

Culture Is Real

While not concrete or tangible, culture is real. When someone falls ill because of a curse, the illness is real. When someone feels peace or joy because appropriate rituals have appeased supernatural beings, the emotional state is significant and real. When people stand in ritual costumes in front of a representative of the Almighty or the State, recite traditional word strings, and exchange specifically ordained pieces of jewelry, they achieve a different social status that affects their kin relations and their economic and social status with the government: They are married! That is the power of culture, and each culture shapes, among other things, the forms and meanings of changes in social status in the group. We cannot see or touch culture, but its effects surround us, rendering culture a very real force.

Culture Is Not Inherited, It Is Learned

Beliefs and values are taught to us both explicitly and tacitly in our families and communities and by mass media. Most readers will not have learned much about spirits, curses, or propitiation rituals but will have been taught in thousands of ways that they are each unique individuals with inalienable rights. The idea that we are individuals with a free will and a "natural" right to our own opinions seems a given to Americans, but it is a cultural idea, quite foreign to others. Observers from other cultures have commented on the ways in which we entrain this idea of individual self-determination in children. I once counted how many decisions a middle-class European-American preschooler was offered in her first waking hour of the day. The decisions—about what to wear, where to dress, what to eat—numbered around 20. The child was actively being taught about her individuality and her right to choose. Later that evening, as adults were discussing where to go for dinner, this child announced, "Those are your ideas, and I have ideas of my own." At age 3, she had already internalized the dominant cultural ideal of individual intellectual independence.

Culture Is Not Idiosyncratic But Is Shared in Human Society

Although it may be carried in the minds of individuals, as some have argued, culture's manifestations are social.

How do you greet your grandfather? With a verbal greeting only, with a hug, or with a kiss on the cheek or his hand? How many such kisses? Do you bend down to touch his feet? Do you shake his hand, then kiss your own and place it over your heart, as a respectful child in coastal East Africa would? Do you seek or avoid eye contact with him? Or do you ignore him? Scholars of culture may dispute whether it is the greeting behavior itself or the shared understanding that underlies it that is the locus of culture, but all agree that culture is shared socially. As such, it is most easily perceived in interactions between and among people. Dickie (2004) reminded occupational therapists that while our focus may be the effects of cultural socialization on individual agency and action, we must not ignore the collective and social nature of culture.

Culture Changes, Usually Slowly

Culture has incredible staying power, is conservative, and does not easily change (Dickie, 2004). But culture is not static, fixed, or immutable. Values, attitudes, aesthetics, lifeways, arts, morals, customs, laws, and the many other things that are included in culture can change in response to the forces of history, politics, and economics. Culture is malleable and dynamic.

Even a cursory glance at the advertising media of the United States in the twenty-first century would reveal that we are encouraged to think that light brown or beige skin, narrow muscular buttocks, large chests, and full lips are aesthetically pleasing in either gender. But it was not always so. For example, before the Industrial Revolution, when European peasants labored outdoors, suntanned skin was not considered aesthetically pleasing; it was considered a mark of low class. The North American and European leisured classes of the preindustrial era took pains to protect the whiteness of their skins even while enjoying outdoor activities. It was not until workers went indoors to sunless factories that suntanning became a mark of expendable income and leisure time and thus became culturally valued. A review of racialized mass media, as done by Marlon Riggs (1986) in the film "Ethnic Notions," shows that full lips were a feature of African origin that was once hyperbolized and demeaned. Now film actresses and models get collagen injections to make their lips fuller. Aesthetics are cultural, and cultures change as human groups encounter each other. When groups of humans come into contact, they influence each other's cultures by imitation, innovation, and even coercion. When the political and economic environment changes, cultures adapt to that change. Dickie (2004) includes a wonderful example of both the changing and changeless aspects of an American cultural ritual, the family reunion. Among the unchanging aspects is the preference for summer outdoor venues, with the elders sitting in the shade reminiscing and the children playing. What has changed for many families is the more inclusive

definition of family, with people invited who would have been excluded just decades ago: same-sex couples, unmarried couples living together, divorced spouses, and step-grandparents.

Culture Drives Values

Culture shapes human values. We rely on our enculturation in one or more cultural worlds to determine what is right and wrong, good and bad, beautiful and ugly, included and excluded, appropriate and inappropriate, safe and dangerous. The cultural values that we have internalized guide our occupational choices and our daily routines for getting things done. Breaking cultural norms that were learned early can provoke a visceral reaction. When traveling in a Muslim country, if I hand someone something with my left hand, I immediately feel wrong and embarrassed because I have been taught to use my right hand for exchanges in Muslim cultures. When I return to the United States, I experience this same feeling of "wrongness" until I readjust to American expectations, usually after a couple of fumbling exchanges with perplexed-looking clerks.

As occupational therapy practitioners, we are often in contact with people who, because of misfortune or a time of crisis, are trying hard to decide what is right and good. We respect their cultures by giving them a psychologically supportive space in which to make meaningful what has happened to them and to apply the values they have lived by.

Culture Is Invisible

Culture is invisible, especially to those who participate in it. It is taken for granted. A common analogy used is "as the water is to the fish." We are often blind to our own cultures, but when we encounter cultural ways that are different from our own, we perceive the otherness, the strangeness of the other group's ways. Still, it takes repeated experiences with entering other cultural spaces, coupled with introspection, just to make our own cultural assumptions visible to us.

Whiteford and Wilcock (2000) point out that the person who is most likely to be blind to his or her own cultural assumptions is white, heterosexual, and middle class. Often, members of minority groups have been socialized into both their own groups' ways and the ways of the dominant majority group, giving them an early experience with crossing cultural boundaries. Majority group therapists might mistakenly think that only minority group "others" have a culture that must be taken into account in therapy. Dickie (2004) suggests that the focus on culture as a problem issue in our clinical interactions could productively shift from the culture of the clients to that of the therapist. That is, rather than seeing that culture must be addressed because some clients come from backgrounds

unlike that of therapists, we might shift focus and see that the limited cultural excursions of the majority of therapists hinder their ability to understand and help all of their clients.

One manifestation of our profession's occasional culture blindness that is repeatedly remarked on in our literature is the emphasis on independence as if it were a naturally valued status. Several authors remind us that interdependence with, or dependence on, particular family members in particular activities may be valued, and hence valid, options for clients (Fitzgerald, 2004; Whiteford & Wilcock, 2000). This often-noted potential clash between therapists' cultural and professional values and those of client families is but one of many areas in which difficulties in cross-cultural collaboration can arise.

Even the "nature" of human nature is a culturally constructed entity, invisible to us because we are immersed in it. In Western culture, we accept without question the unity of consciousness and continuity of personhood as obvious and natural. Many cultures include ideas about consciousness and personhood that would strike us as unusual. Most of us do not believe, for example, that we physically travel in our dreams to other places, that spirits of deceased ancestors inhabit the landscape around us, or that our bodies can be literally taken over—possessed— by other active entities. Still, our popular culture in recent years includes stories of angels helping humans, and we seem to be increasingly fascinated by such possibilities. Ideas about spirits, malign or beneficent, and the perhaps permeable limits of the person are part of spiritual practices or cosmologies, and as the Occupational Therapy Practice Framework directs, understanding these ideas as they pertain to clients is within the realm of our practice.

HUMAN DIFFERENCES THAT MAY INFLUENCE CULTURE BUT ARE NOT PRECISELY CULTURAL

Ethnic and Racial Diversity

Culture is not the same as **ethnicity** or race. *Culture* is not a polite synonym for the word *race,* although people who are uncomfortable with discussing race and ethnicity sometimes use it that way. Many occupational therapy authors caution against making this mistake (Bonder, Martin, & Miracle, 2004; Evans, 1992; Fitzgerald 2004). Ethnic groups, according to Weber's (1922/1968) classic definition, are groups that "entertain a subjective belief in their common descent because of similarities of physical type or of customs or of both, or because of memories of colonization and migration" (p. 389). Ethnic identity can be self-selected and built from within a group, imposed from outside it, or both. It is dynamic and fluid, changing in response to social change (Cornell & Hartmann, 1998).

Race and ethnicity are socially constructed categories, concepts agreed on in public and private discourse that can be understood only in the context of the history of their employment in a particular place.

When ethnic labels are assigned from outside the group, the group's phenotype or appearance is the basis for group assignment. **Phenotype**, the actual physical appearance of an individual, is different from **genotype**, which is the exact genetic makeup of an individual. Even identical twins, whose genotypes are exact copies of one another, have subtle phenotypic differences, including their fingerprints.

In the sad history of human atrocities, a particular phenotype or appearance is often featured in propaganda aimed at isolating or destroying an ethnic group. Thus, Hitler's propaganda included descriptions of the "Jewish type." Hutus in Rwanda massacred those they perceived as Tutsis, people who were said to be taller, with narrower, longer noses. For centuries before, under Belgian and German colonialism, Tutsis—or those perceived as Tutsis—had been favored with land and employment and helped to oppress those perceived as Hutus. Individuals who do not fit the propagandized phenotype in situations of ethnic conflict or genocide are more likely to escape.

Race—although an operative concept in American social life, politics, economics, and entertainment marketing—is not a biological entity. Biologists have shown that there is more variation within than between the so-called races of humans, thus invalidating the categorization on a statistical basis. Moreover, with race as with ethnicity, there is often a difference between phenotype and genotype. To say that race is a bogus concept biologically or that it is socially constructed, however, does not mean that race is not psychologically or socially real. Dealing with race relations is a very real part of life. Humans are killed on the basis of race. Humans are denied or given rights and privileges on the basis of race. Although race and ethnicity are not the same as culture, the historical experience of oppression—or, for that matter, of privilege—based on racial, ethnic, religious, or other group membership can shape culture. Therefore, although race, ethnicity, or religion and culture are distinct concepts, they may overlap, interact, and intersect with each other.

Large groups, such as those based on race, language, religion, or national origin, are often more heterogeneous than homogeneous and might not share much overlap in cultural beliefs, attitudes, and practices. For example, though African Americans are grouped in a racial category, cultural practices vary within the group (Llorens, 1971). American citizens of African descent who have recently and voluntarily migrated from Africa or who have come from the Caribbean have cultural beliefs, practices, and lifeways that are different from those of African Americans whose families have been in the United States since being forced there by enslavement; nevertheless, these groups share a racial designation in our social system of labeling race. Teasing apart race, ethnicity, and culture becomes more tricky when we realize that social forces or practices that are used to isolate a racial or ethnic group will affect that group's culture. Racial bias or discriminatory treatment is something that most Americans of African descent have experienced. Some commonly held cultural beliefs and practices have been organized in response to this experience and have functioned to protect family members in a hostile environment.

Race, ethnicity, class, religion, language group, sexual orientation, and gender diversity all interact and affect the cultural adaptation of groups of people. Cultural traditions often carry with them an emphasis on a shared language, just as language is shaped by culture. Consider all speakers of Spanish as a first language. It would not be accurate to say that they share a "Spanish" culture. Still, many of their cultural values, health practices, and occupational traditions employ terms unique to Spanish that do not have a simple, precise translation in other languages.

Our nation includes increasing numbers of families and individuals who are multiracial and multicultural. The 2000 Census allowed multiracial Americans for the first time to check all of the categories that apply in describing their race. In the past, such citizens were forced to pick one race. Approximately 2.4% of Americans, nearly 7 million, identify themselves as of more than one race.

Language Group Diversity

Because occupational therapy practitioners rely on interviews for gathering data relevant to treatment planning, perhaps the diversity that most complicates the treatment process is language diversity. According to the 2000 census, nearly 47 million Americans speak a language other than English at home. Some practitioners are naive about issues surrounding cross-cultural communication (Wardin, 1996). Wardin surveyed occupational therapists to identify both difficulties in cross-lingual communication and examples of successful interaction during the evaluation process. She found that when family members or professional translators were not available, gestural communication was considered reliable. Yet, gestures are not universal, and without an understanding of what gestures mean in different cultural contexts, therapy practitioners risk insulting their clients. In North America, when we gesture for someone to come close, we flex the index finger, and the more pleading and apologetic we are, the more likely we are to minimize the range and the size of this beckoning gesture. In East Africa, a polite "come here" signal must be made with the whole hand and forearm, and using a digit or minimizing the size of the gesture is a serious insult. Signaling "okay" with thumb and index finger or with a thumbs-up seems positive and benign to many of us, but in some cultures these gestures are obscene. Even a smile can be misinterpreted. Smiles may be seen as sly indications of the smiler's superiority

---

BOX 6.1

TIPS TO FOLLOW WHEN USING AN INTERPRETER

- A trained medical interpreter is held to the same standards of confidentiality that any other health professional must follow. If using a family member or bilingual staff member instead of a trained interpreter, remind the interpreter in front of the client that everything that you and your client say is confidential information, not to be repeated.
- Address the client directly. Do not converse with the interpreter about the client.
- Do not ask for a summary or expect the interpreter to filter important from nonessential details. It is the inter-

preter's job to preserve and convey the client's speech and emotional tone in as much detail as possible. A professional medical interpreter conveys not only what is said, but also how it is said. This takes time, so allow extra time.
- Pause frequently and ask whether the client has questions. It is both your role and the interpreter's role in a health care situation to minimize the client's discomfort and to ensure mutual understanding.

---

or that the one smiled at is appearing foolish. One foreign student in the United States noted that he felt that he should return to his room to make certain his trouser fly was closed, because he could think of no other reason for his fellow students to persist in grinning at him so. Clearly, nonverbal communication is an inadequate basis on which to form a therapeutic relationship across cultures.

Many respondents to Wardin's (1996) research worked in systems in which they relied on family members for translation. Problems occur, however, when family members serve as interpreters, frequently because they give help or suggest responses on evaluations. Furthermore, junior family members may experience role strain when required to ask personal questions of, or assertively give directions to, senior family members. Federal legislation mandates provision of translation services in primary health care facilities that accept federal funds (National Center for Cultural Competence, 2000). In some areas, medical interpreter services are available by telephone. See Box 6.1 for tips on using interpreters effectively.

Compared to citizens of other nations, those of the United States are more often monolingual and less aware of cross-cultural communication issues. Wardin's (1996) study showed that practitioners who were functionally bilingual reported more effective practice strategies, even with clients whose languages they did not speak. Thus, there is evidence that language study sensitizes practitioners to issues surrounding limited English proficiency.

Communication is not a simple or straightforward process. When analyzed closely, it can be seen as fraught with so many complications that one is amazed that we understand each other at all. Practitioners acknowledge the need for skillful use of interpreters and for active listening to check that the meaning received is the one intended and to attend to both verbal and nonverbal aspects of communication.

Diversity of Sexual Orientation

Sexual orientation is the physical and emotional attraction toward intimacy with others, seen in spontaneous feelings and erotic desires (Hall, 2001). Sexual orientation, whether heterosexual, homosexual, bisexual, or asexual, is not a choice or a preference (McNaught, 1993a). To say, for example, that a man has a homosexual orientation is not to say that he finds all other men sexually attractive, that he cannot control his sexual impulses toward them, or that he finds women repugnant. It simply means that the individuals to whom he finds himself amorously attracted are male. Homosexual people do not have a particular "lifestyle" or culture; neither do heterosexual people. Both groups comprise people who have many different lifestyles, cultures, races, ethnicities, social classes, and occupations. The experience of group persecution, however, is a strong stimulus to developing shared cultural understandings and values and to the formation of communities, shared rituals such as the annual Gay Pride parades, and unique vocabularies.

The 2000 Census reported that 594,391 households in the United States were made up of same-sex couples who defined themselves as partners; this was 1% of all coupled households. We do not know what makes the majority of the population heterosexual. Similarly, we do not know causes of other sexual orientations, and it is useful to realize that the range of sexual orientations may be an expression of simple natural variations in humans (Hall, 2001). There is nothing that parents, families, friends, or lovers do to "make" people have one orientation or another, and it is difficult if not impossible to change a person's sexual orientation (Hall, 2001). Many myths and stereotypes surround sexual orientation. Dominant cultural disapproval (including harassment and murder of gay individuals) makes it difficult for those who

realize that they are not attracted to people of the opposite sex to apply a sexual orientation label to themselves. Self-acceptance is challenged, and the process of reaching psychosexual maturity is complicated for many young people with something other than a heterosexual orientation because our mainstream culture is steeped in images that depict some varieties of sexual expression and sexual orientation as evil or wrong (McNaught, 1993b). This is not to say that gay or lesbian young people are less psychologically healthy but rather that they may find reaching sexual maturity to be fraught with more challenges (Crepeau, 1998; Walsh & Crepeau. 1998). There are many good video, print, and Internet resources for those who want more information on sexual orientation; I recommend books and videos by Brian McNaught (a complete list can be found at http://www.brian-mcnaught.com/resources. html) and the interactive website Sex 101 (http://www. yforum.com/sex101.html), which allows readers to post questions and responses.

Occupational therapy scholars have observed that understanding sexual orientation is important as a theme of meaning and identity in clients' lives and that, as such, it is often expressed in choices of occupations (Jackson, 1995; Wood, 1992). Because their lives are about more than just their sexualities, many people prefer terms such as *gay* and *lesbian* to the term *homosexual*. As we strive to understand the fullness of our clients' lives and occupations, we cannot ignore the sexual dimensions of their personhood. That does not mean that we need to know the specifics of the sexual activities in which they engage— except at times when we might become involved in helping people with disabilities to solve kinesiological problems involved in sexual expression. For all clients, skilled practitioners create an environment in which acceptance of sexuality, as with acceptance of culture, is clear and invites true collaboration. In establishing accurate empathy with our diverse clientele, skilled occupational therapy practitioners avoid **homophobia**, just as they avoid racism and ethnocentricity. Creating a climate of tolerance and acceptance in the workplace also means that gay, lesbian, and bisexual coworkers can focus their efforts on patient care and not on having to keep their identities secret (McNaught, 1993a)

MYTHS, STEREOTYPES, XENOPHOBIA, AND GENERALIZATIONS

With regard to multicultural awareness, a **myth** is an unfounded or poorly founded belief that is given uncritical acceptance by members of a group. Myths operate in support of existing or traditional practices and institutions. **Stereotypes** are mental pictures based on myths that lead people to associate a characteristic or set of characteristics with particular groups of people. **Xenophobia** is an

unreasonable fear or hatred of those different from ourselves. Is xenophobia just part of human nature, as some have argued, or is it taught and learned, handed down from adults to children as part and parcel of a social group's culture? The fact that xenophobia can be unlearned and that some humans are consistently attracted to those who are different from themselves argues against a view of humans as naturally suspicious of other humans not of their own group.

The tendencies to generalize, however, and to cluster perceptions in memory do appear to be inherent parts of the human mental apparatus. Piaget (1969) described the development of children's thinking in terms of forming and refining schemata for grouping objects and creatures in the natural world around them. Thinking about such cognitive clustering can provide some insights into how myths and stereotypes about groups of others are formed. It is a way to begin to undo some of the myths and stereotypes we might have incorporated into our own thinking about human diversity.

Let's say that at some point in your youth, you heard the phrase *woman driver.* The circumstances under which you heard this term employed allowed you to understand quickly that it was a phrase meant to disparage the abilities of women to operate motor vehicles safely and efficiently. Having heard the phrase used once or twice, you internalized this concept, even if just on a trial basis. With the concept embedded in your mental apparatus, you were readily able to incorporate and file away in this conceptual category any and all instances you noted personally or heard about in which a female did indeed operate a motor vehicle in an unskilled or unsafe manner. Conversely, there was no handy cognitive schema in which you might mentally record, in a ready-made category, all incidents or reports of males driving badly. Challenged to recall instances of or anecdotes about bad driving by females and by males, you would much more readily retrieve from memory all those precoded instances of bad driving by females. A concept is introduced, and as with a self-fulfilling prophecy, evidence begins to be amassed through experience— experience filtered through previously learned cognitive categories. You might well conclude that women are worse drivers than men. Then you would be confronted with a different reality. Insurance actuarial tables show that, in fact, women are better drivers than men, and insurance companies, large and small, honor that truth in the way they structure differential rates for coverage by gender in certain age groups and where allowed under state law.

Humans apparently cannot turn off the grouping, generalizing, and schemata-building aspects of their minds. However, we can rigorously examine the generalizations we make about other humans and the conclusions we draw. To practice competently and ethically with a diversity of individuals and groups, health care professionals accept the responsibility of examining their generalizations, because adhering to myths and stereotypes leads to

poor health care outcomes for stigmatized groups. For example, people of color have less access to health care, receive inferior health care services, and experience worse outcomes of care, including increased rates of mortality and morbidity in many disease categories (Williams, Lavizzo-Mourey, & Warren, 1994).

Generalizations about cultural or racial groups are not all negative or destructive. Health care professionals have sometimes found it useful to generalize from published lists of characterizations of particular ethnic, cultural, or language groups. Recent discussions in occupational therapy literature have joined this text in stating that such lists ought to be used with caution but that learning specifics about cultural groups is a place to start in attaining multicultural competence (Bonder, Martin, & Miracle, 2004; Dickie, 2004; Wells & Black, 2000, Whiteford & Wilcock, 2000) As an example, here is a list that contrasts beliefs, values, and practices of Native Americans with those of Anglo-European Americans, so all the statements are considered relative comparisons. In contrast to European Americans, Native Americans are characterized as (Joe & Malch, 1992):

◆ More group oriented than individual oriented
◆ Having respect for elders and experts
◆ Viewing time and place as permanent and settled
◆ Being introverted and avoiding ridicule or criticism of others
◆ Being pragmatic and accepting of what is
◆ Emphasizing responsibility for family and self more than authority over or responsibility for larger social groups
◆ Attending to how others behave more than to what they say they think or feel, and seeking harmony

This may be useful information to have as a starting point for observations of and conversations with a particular Native American client or family, but it is important to remain open to the possibility that the individual or various family members may espouse and enact all, some, or none of these beliefs and values. If, for example, the hypothetical client were an urban American Indian Movement activist leader, it is unlikely that she would concern herself only with self and family or pragmatically accept the status quo. The more information that you have about the social history and context of an individual or family group, the better able you will be to discern whether published descriptions of these cultural others apply.

Attempts to generalize from knowledge of another's religion present particular difficulties. While North Americans and Europeans tend to give a religious tradition complete allegiance, excluding the possibility of participating in religious practices springing from other traditions, this is not the rule worldwide. Muslims in North, West, and East Africa, for example, do not experience rituals aimed at recognizing or propitiating capricious and problematic spirits as contradictory to or disrespectful of their Islamic

faith. Similarly, spirit possession and animal sacrifice practices by Brazilians practicing candomblé or Cubans practicing santeria, both of which blend elements of Christianity with worship of West African deities, do not see these as interfering with their practice of Roman Catholicism. Conservative orthodox leaders of Sunni Islam or of Roman Catholicism may frown on such practices, but their disapproval is somewhat moot from the perspective of the practitioner–client relationship and attempts at cross-cultural understanding. Medical anthropologists have long observed that, faced with adversity, humans generally try any remedies they perceive as useful, even if those remedies do not fit into one systematic worldview or set of beliefs in the supernatural.

It is also wise to consider the forces of assimilation in applying generalizations. As was noted above, mass media and interactions with other social group members provide a powerful impetus for cultural or racial minorities to adopt dominant group values, beliefs, and practices. This is seen most readily in generations born to immigrant citizens. A client's personal ethos (worldview and approach to life) might well be a creative blend of cultural elements from the previous society or older generation's culture and the new society and culture the client has entered (see Case Study 7.A on the Willard & Spackman Website).

Finally, it is important to realize that the process of generalizing about culturally different others is multidirectional. As you interact with those who are different from you and test hypotheses based on your learned generalizations, others will be doing the same in regard to you. Myths and stereotypes about all cultural and racial groups, including European Americans, abound. Books such as Henry Louis Gates's *Colored People* (1994), Anne Fadiman's *The Spirit Catches You and You Fall Down* (1997), and Anna Deavere Smith's *Twilight, Los Angeles, 1992* (1994) and *Fires in the Mirror* (1993) provide priceless insights into cultural and racial myth making and stereotyping in America. *Distant Mirrors* (DeVita & James, 2002) includes many essays that detail immigrants' and visitors' impressions of American culture. Some of them will probably surprise you.

CULTURE AND OTHER FORMS OF DIVERSITY IN OCCUPATIONAL THERAPY THEORY AND PRACTICE

Mattingly and Beer (1993) offered two reasons for occupational therapy practitioners to strive for an accurate understanding of their clients' cultural backgrounds: to allow for collaboration in goal setting and treatment planning and to individualize therapy. I would add three others: to ensure accurate assessment, to refine occupational therapy theory in ways that take all humans into account, and to increase the likelihood of equitable treatment. Underlying all of these

goals of culturally sensitive treatment is the imperative that we establish accurate empathy for our clients.

African Americans, Hispanic and Latino Americans, and Native Americans are underrepresented in our profession. More than 90% of occupational therapy practitioners are white, whereas 76% of the U.S. population is white. Although race and ethnicity are not the same as culture, they are attributes that, like culture, are marked as differences in North American society. As such, they can create challenges to interpersonal understanding between individuals who come from different groups, just as class and culture do. Moreover, occupational therapy practitioners come from a narrower range of class backgrounds than do their clients, and all practitioners share the socializing influence of higher education. If we do not pay attention to differences in a respectful way and do not reflect on our own potential for bias, we will fail at establishing accurate empathy for our clients and good working relationships with them. Occupational therapists of different races responding to a survey agreed on a list of beliefs and values but ascribed different sets of values to ethnic groups other than their own (Pineda, 1996).

We attend to cultural differences during the process of assessment and attempt to choose evaluation instruments and strategies that are not culturally biased and to interpret results correctly. By their very nature, standardized norm-referenced assessment tools make assumptions about normalcy that may be culture bound. Most testing instruments assume characteristics of modal individuals, often based on middle-class European-American lifeways and experiences. For example, Law (1993) found that assessments of activities of daily living (ADL) and instrumental activities of daily living reflected North American dominant cultural values regarding independence and individual rights. Occupational therapy researchers have studied locus of control—a measure of feeling self-determined and empowered—in a variety of populations and found that people of color often score lower (or more externally controlled) than anticipated, perhaps because of the demoralizing influences of racism (Elliot & McGruder, 1995; Janelle, 1992; Spadone, 1992). Occupational therapy practitioners have found that pediatric assessment tools normed in the United States may be biased, inapplicable, or simply not useful in evaluating poor children, ethnic minorities, disadvantaged orphans overseas, or recent immigrants (Bowman & Wallace, 1990; Colonius, 1995; Fudge, 1992; Miller, 1992; Myers, 1992). Even scales of infant behavior might not apply where child-rearing practices differ with culture (Packir, 1994).

A concern with removing cultural bias, insofar as possible, from assessments of ADL in adults inspired the design of the Assessment of Motor and Process Skills, an occupational therapy assessment tool that allows clients choice in what activities to perform and how to perform them. Work is ongoing to determine whether this approach does indeed eliminate bias and lead to cross-cultural valid-ity; results to date are promising (Goto, Fisher, & Mayberry, 1996; Stauffer, Fisher, & Duran, 2000).

Humphry (1995) described how chronic poverty, an experience that is unequally shared across cultural and racial groups in the United States, depersonalizes and erodes the sense of self, alters children's developmental progression, and causes potential conflicts between practitioners and clients or their caregivers around the five universal problems of time orientation, activity, human relationships, human nature, and control of natural forces. These values conflicts have implications, not only for testing that purports to measure locus of control, human motivation, or ADL performance, but also for how we represent humans and human occupation in occupational therapy theory.

Occupational therapy theoreticians continually build and refine models for practice. The profession values this scholarly activity. Refinement takes place as scholars open their work for criticism and debate among their peers. Rigorously examining the culture-based assumptions of a practice model is one way to test it.

The model of human occupation, one of the more encompassing theories in occupational therapy, incorporates multiple levels of data gathering about humans' skills, habits and roles, interests, and motivations embedded in a social and cultural environment. The model emphasizes humans' relationships to time and includes locus of control and belief in personal effectiveness as elements in the volitional regulation of playful and productive output (Kielhofner, 2002). Yet making statements about what is normal, universal, functional, or adaptive in these realms is almost impossible, for these areas are largely defined by culture. Some theoreticians working on the model of human occupation have moved away from standardized, quantification oriented-assessments of volition in favor of a more qualitative approach of eliciting narratives (Helfrich & Kielhofner, 1994; Helfrich, Kielhofner, & Mattingly, 1994). Others have questioned the adequacy of attention to the cultural and social environment, much mentioned but little analyzed in earlier descriptions of the model, and have called into question the assumed hierarchy among subsystems with volition driving habituation and skill performance (Haglund & Kjelberg, 1999).

From its inception, occupational science has embraced narrative, or story making, as the best means to understand clients' experiences of their illness or disability (Clark, 1993). The emphasis in occupational science on emic (insiders') perspectives gives it the potential to cross cultural barriers. Concern with the client's own account of his or her life is part of the occupational therapy tradition (Frank, 1996). In the application of narrative methods of assessment across cultures, however, it is important to recognize that what is a satisfying narrative to Western minds has a particular linear structure. That structure has been discussed (and prescribed) in Western culture since Aristotle's time. Proponents of narrative methods of evaluation admit

that the "story" arrived at by the client (and family) and practitioner is the result of a negotiation between the client's telling and the practitioner's reconstruction of the story (Frank, 1996). When occupational therapy practitioners interview clients to discover their activity goals or the meanings that activities hold for them, they sometimes elicit stories that make no sense to the practitioners. The task for ethical practitioners is to push themselves outside the comfortable but invisible confines of their own culture and class to attempt an accurate understanding of their clients' worldviews and life situations. Doing so is a necessary step in collaborative goal setting, accurate assessment, individualized treatment planning, and equitable treatment provision.

See Case Study 7.B on the Willard & Spackman website for one example of the process of cross-cultural negotiation across several kinds of diversity.

ACHIEVING MULTICULTURAL COMPETENCE AS AN OCCUPATIONAL THERAPY PRACTITIONER

There are almost as many definitions of cultural competence as there are of culture. Fortunately for the length of this chapter, there is a great deal of agreement on what is involved in becoming a culturally competent practitioner. Most models of multicultural competence encompass the idea that knowledge of self and realization of one's own cultural values and orientations constitute a necessary first step. This aspect is often referred to as *cultural awareness* (Dillard, Andonian, Flores, MacRae, & Shakir, 1992). In tandem with cultural awareness is the need for *cultural sensitivity*, defined as an openness to the cultural values of others (Dillard et al., 1992).

Programs aimed at increasing awareness of one's own culture often begin with examination of dominant North American cultural values, to make those values less invisible to those who have assimilated them and to diminish ethnocentrism or the tendency to see one's own culture as the norm and expectation against which others are compared. The list below includes some observations about dominant North American cultural values (DeVita & James, 2002; Humphry, 1995; Pineda, 1996; Sanchez, 1964). In some cases, the values orientation of the dominant culture and that of the occupational therapy profession coincide, creating a strong bias that we must be aware of—and be willing to give up—when working with those whose values may be different.

In comparison with other cultural groups, dominant group members in the United States of America have been said to:

◆ Value the future over the present and value long-range planning and delaying gratification

◆ Value individuality and place the good of one individual over that of the rest of the social group
◆ Value independence over interdependence and group members doing for themselves over being served by others
◆ Be more secretive and private about their money and property than about their sexual behavior
◆ Resist sharing space or food without prior notice and planning and dislike "drop-in" visitors
◆ See the locus of identity as the individual and define the social unit primarily as the nuclear family
◆ Desire and value a sense of being in control and not to readily acquiesce to situations others may see as fate
◆ See science and technology as a source of control over the natural world, including humans
◆ Value physicality and doing over introspection and being
◆ Believe that humans are nearly perfectible and value discipline and learning as a means toward that end

For European-American practitioners, increasing cultural awareness and learning to establish accurate empathy begin with acknowledgment of the privileges and advantages inherent in membership in the dominant group (Evans, 1992; Matala, 1993). This is not an easy step, but it is a necessary one. Dominant cultural group members might have been raised with the myths that humans may pull themselves up by their bootstraps and that hard work always pays off. Moreover, they might have worked very hard for their achievements. Thus, they come to see their status as a just reward and wonder why others have not achieved similarly. The privileges, small and large, that accompany dominant group membership status might be invisible to them. Box 6.2 shows a sampling of such privileges, taken from a longer list by McIntosh (1997).

Cultural sensitivity follows when learners are aware of their own value orientations and are ready to explore those of others nonjudgmentally. Contact with empowered individuals whose culture, race, ethnicity, class, gender, or sexual orientation is different from their own is the most highly valued sort of activity for increasing cultural sensitivity.

While some discussions of cultural competence emphasize this dyad of awareness and sensitivity, others include a third dimension: skill (Wells & Black, 2000). The inclusion of the dimension of skill reminds us that multicultural competence is more than a set of attitudes or a general understanding; rather, it encompasses a learned set of actions that can be practiced and refined. Bonder and colleagues (2004) recommend three general actions therapists can practice for increasing multicultural competence: (1) carefully attending to the "interactional moment," taking into account as many verbal and nonverbal aspects of the communication as possible; (2) being curious about the meaning of all that one notices in so doing; and (3) engaging in reflective assessment of one's own com-

BOX 6.2

ACKNOWLEDGING PRIVILEGE INHERENT IN DOMINANT GROUP MEMBERSHIP

- If I wish, I can arrange to be in the company of people of my race most of the time.
- I can avoid spending time with people whom I was trained to mistrust and who have learned to mistrust my kind or me.
- If I should need to move, I can be pretty sure of renting or purchasing housing in an area that I can afford and in which I would want to live.
- I can be pretty sure that my neighbors in such a location will be neutral or pleasant to me.
- I can go shopping alone most of the time, pretty well assured that I will not be followed or harassed. Whether I use checks, credit cards, or cash, I can count on my skin color not to work against the appearance of financial reliability.
- I can turn on the television or open to the front page of the paper and see people of my race widely represented.
- When I am told about our national heritage or about "civilization," I am shown that people of my color made

it what it is. . . . I can be sure that my children will be given curricular materials that testify to the existence of their race.
- I can arrange to protect my children most of the time from people who might not like them.
- I do not have to educate my children to be aware of systemic racism for their own daily physical protection.
- I can be pretty sure that my children's teachers and employers will tolerate them if they fit school and workplace norms; my chief worries about them do not concern others' attitudes toward their race.
- I am never asked to speak for all the people of my racial group.
- I can remain oblivious of the language and customs of persons of color who constitute the world's majority without feeling in my culture any penalty for such oblivion

Adapted from McIntosh, P. (1997). White privilege and male privilege: A personal account of coming to see correspondences through work in women's studies. In R. Delgado & J. Stefancic (Eds.), Critical white studies: Looking behind the mirror *(pp. 291–299). Philadelphia: Temple University Press.*

munication in interactions. While face-to-face contact and immersion in culturally distinct environments is extremely useful, much can also be learned from reading autobiographies and novels written by those different from oneself.

CONCLUSION

Developing multicultural competence is a challenge, but the learning that occurs along the way can be a joy. Nothing is more interesting than the varieties of ways humans use to solve the problems of daily living and the variety of occupations that they choose. An appreciation of culture allows the skilled practitioner insight into how something as mundane as home canning can take on great importance to individuals as they write through occupation the stories of their lives.

Looking for culture through careful observation of and interaction with others, coupled with introspection of self, enables the establishment of accurate empathy between practitioner and client. Cultural difference then becomes a basis for understanding and working together and not a barrier to therapeutic gains. One of the encouraging developments in our profession has been the con-

scious use of cultural understanding in developing health promotion programs for healthy and at-risk populations. For example, see DeMars's (1992) description of community consulting in a Native Canadian village; Frank and colleagues' (2001) description of an occupation-based multidisciplinary program focused on helping black and Latino youngsters become the producers of culture, not just the passive consumers of mass cultural products; and Barnard and colleagues' (2004) description of a project aimed at enhancing wellness in a predominantly black rural farming community in North Carolina.

There are many excellent resources to help you on your personal journey toward multicultural competence. Websites abound. Book-length works on health care and culture by occupational therapists include Wells and Black's (2000) *Cultural Competency for Health Professionals* and Bonder, Martin, and Miracle's (2001) *Culture in Clinical Care.*

Socioeconomic Factors and Their Influence on Occupational Performance

CATHY LYSACK

Learning Objectives

After reading this chapter, you will be able to:

1. Distinguish between socioeconomic status, socioeconomic position, and class.
2. Understand that health is related to the person's position in the social hierarchy.
3. Identify client groups that are at greater risk for occupational performance difficulties related to socioeconomic disadvantage.
4. Name the mechanism by which social inequalities adversely affect health.
5. Describe five major social determinants of health that influence the occupational performance of clients.
6. Describe three actions that occupational therapy practitioners can take to reduce the impact of social inequalities and health disparities in clients' lives.

INTRODUCTION

The focus of this chapter is the social causes of health and disability and how socioeconomic factors influence people seeking and receiving occupational therapy services. As the case study illustrates, the environment in which Annie and Desmond lived influenced their chances for health. Desmond might have contracted his illness in an unhealthy workplace. Like Annie and Desmond, their children attended inner-city public schools that might

Annie is 72 years old and spent 11 days in the hospital. She "took a spell" and tumbled down her basement steps, fracturing her left hip and two ribs on her right side. She is using a wheelchair now but hopes that it is temporary. Annie is worried about managing at home. To make matters worse, she is still coping with the consequences of a mild stroke two years ago. Annie lives in inner-city Detroit. Her house has two small bedrooms and a bathroom on the second floor, with laundry facilities in the basement. She is a widow, and her only surviving child, a son, lives in Chicago. Throughout her life, Annie stayed home to raise three children while her husband Desmond worked at an automotive supply company. Unfortunately, after 31 years of work, Desmond was laid off at age 52. Shortly afterward, he became ill with lung cancer and died. Desmond was a nonsmoker, and workers in his plant wondered whether their jobs had made them sick. This was never determined. Making things worse, the company's financial problems brought changes in pension benefits transferred to surviving spouses. Shortly after Des passed away, Annie learned that she would have to get by on her monthly Social Security check and Medicare. She would receive nothing from her husband's pension.

Just before being discharged from the hospital, Annie was assessed by an occupational therapist and was given recommendations about how to bathe and dress and how to cook and clean safely and independently once she returned home. She was also given information about Dial-a-Ride, a transportation service for older adults and people with disabilities, and the name of a senior center where she could take exercise classes and participate in social activities on a drop-in basis. Annie was disappointed that she would not receive an in-home evaluation as several other women she met in the hospital had had. According to Annie, these women were getting "nice solid bathseats and grab bars." It was also rumored that some might get "adjustments to their kitchen cupboards" and even "a fancy ramp." Annie's insurance covered none of this, not even the raised toilet seat her therapist told her would help to avoid another fall. In addition, her doctor said that her mobility problems were "too mild" to qualify for further rehabilitation.

After three weeks at home, Annie is more worried than ever about the slowness of her recovery and her mounting out-of-pocket expenses for medications. Friends at Annie's church are bringing meals and helping with groceries, but Annie is anxious to be more self-sufficient. Still, she doesn't trust her legs "not to buckle out from under me." In a phone call to her son, she even expressed fear about going out in her neighborhood, saying that she felt like "a sitting duck" for anyone who "took it into their heads to get up to no good." Annie wonders whether the women she met weeks ago in hospital are faring better than she is and how different it would be if she could get even a little more help. She is praying that the good Lord will "see her through."

not have provided an optimal education. In addition, since medical benefits are linked to employment, the family might not have had an equal chance to achieve good health. How good has Annie's family's health care been through the years? How does this compare to the families of the women Annie met during her hospital stay? It is also worth asking how fair it is that Annie does not qualify for home support services and why there is no accessible public transportation or Meals-on-Wheels programs in her neighborhood.

Annie is struggling to regain mobility and independence after her fall, but it is not her bodily impairments that dictate her future now. Rather, it is her socioeconomic resources, shaped by a range of physical and social conditions over a lifetime and her place in the social hierarchy, which is dictated by the differences and inequalities among the groups Annie belongs to. These differences systematically advantage some and burden others. In this chapter, we will focus on those people who are systematically disadvantaged—those rendered most vulnerable by underlying social structures and political, economic, and legal institutions. Groups that are known to experience disadvantage in this sense include women, but even more so, visible minorities, the poor, and people with disabilities. As others have pointed out, occupational therapy practitioners as a group are overwhelmingly white and middle-class (Wells & Black, 2000). In general, we live more privileged lives than nearly all our clients do. One of the responsibilities of a competent and ethical practitioner is to recognize that such differences have deep historical roots that shape the health choices and behaviors of clients of well as the responses as health professionals. The reality of social and economic influences on health calls for a vigorous examination and discussion of the array of factors that influence health and disability in society and how these influence our practice.

DEFINING THE SOCIAL CAUSES OF HEALTH AND ILLNESS

What Do We Mean by Socioeconomic Position, Class, and Social Mobility?

Several terms are used to signal the influence of social and economic factors on health, and each term has a slightly different meaning. One of the most familiar terms is **socioeconomic status** (SES). This term refers to occupational,

educational, and income achievements of individuals and groups. SES may overemphasize social prestige and underemphasize the role of material resources in shaping one's life chances, particularly related to health. Thus, as Krieger (2001) suggests, it might be time to replace the term *SES* with the term **socioeconomic position**.

The term **class** is also used to indicate social differences, as in *lower class*, *working class*, *middle class*, and *upper class*. Class is not easily defined. To some, class denotes culture and taste or particular attitudes and assumptions, lifestyle, or source of identity. To others, it just means having money. Classes are groups of people with similar economic means, especially those with similar levels of ownership of property and capital. To varying degrees, all societies are stratified by class. Since the United States is an industrialized free-market economy, the degree to which we move up or down the social ladder, something sociologists call **social mobility**, is in large part dictated by our class, that is, by our income and wealth.

What Are Social Inequalities, the Social Gradient, and Health Disparities?

The terms *social inequalities, the social gradient*, and *health disparities* come to us from the public health literature and are closely related to class. **Social inequality** refers to the pattern of unequal rewards and opportunities that accrue to different individuals and groups in society, particularly those rewards and opportunities that are judged to be unfair, unjust, avoidable, and unnecessary (Krieger, 2001). While some differences between people in society are fixed and cannot be changed, others are morally wrong and can be improved. For example, discrimination against people on the basis of gender or sexual orientation is morally wrong. Social inequalities are a regrettable reality in the United States, and much work needs to be done to address the underlying factors that create these inequalities.

One reason that social inequalities are of great concern to health professionals is that social inequalities put people at risk for poorer health. Life expectancy is shorter and most diseases are more common farther down the social ladder. The reality that health diminishes with each step down in the social hierarchy has been called the **social gradient**. Decades of research has shown this is true in both rich and poor societies (Marmot & Wilkinson, 1999). Making matters worse is the fact that "upward mobility," that is, doing better and having more than our parents, is happening less than we thought. Americans are more likely, not less likely, than they were 30 years ago to remain in the same class into which they were born (Bradbury & Katz, 2002). While equality and reward are embodied in the ideal of the American dream, the dream is accessible only to some.

Health disparities refer to differences of treatment and health care services that are unfair and may be the direct result of either underlying social inequalities or improper actions by professionals within the health system. The *Healthy People 2010* report (U.S. Department of Health and Human Services, 2000a) defines disparities as differences that occur by gender, race or **ethnicity**, education or income, disability, geographic location, or sexual orientation. The factors that contribute to health disparities are a major preoccupation in the United States because there is mounting evidence that members of minorities receive substandard levels of health care and have much poorer health. Studies have found that even after symptoms and insurance coverage are controlled for, doctors are more likely to offer whites life-preserving treatments, including angioplasty and bypass surgery for cardiac disease, and are more likely to offer minorities various less desirable procedures such as amputations for diabetes (Institute of Medicine, 2002). This research indicates that clinical encounters between members of minorities and health care professionals may be the source of additional poor treatment. Stereotyping and institutional racism are widely recognized as unjust forces in the health care environment that must be changed. The longer-term consequences of a lifetime of perceived racism are also coming to be understood as adversely influencing health (Clark, 2004). Differences in age, gender, and ethnicity will always exist; it is wrong, however, when these differences lead to unequal care. To what extent do occupational therapy practitioners discriminate against minorities, the poor, and the elderly? Do their attitudes restrict access to high-quality occupational therapy services for these individuals?

The Intersections of Gender, Ethnicity, Age, and Disability

The notion of class differences and social inequalities is not an appealing one. Americans typically avoid talking about this problem (Fussell, 1983; hooks, 2000). The notion that we all have equal chances and opportunities is an idea that we want to believe is true. For example, we want to believe that we can all go to the schools of our choice, enter any occupation we desire, and be free to participate in any leisure activity that appeals to us. On the other hand, we know from experience that we often have to change our plans or reconsider our goals because we lack the necessary means to achieve them. The ability to achieve what we want out of life depends on our resources—quite often, financial resources, but not entirely. A positive outlook on life or a strong family support system, for example, may get us through a difficult period more successfully than having a large amount of money. Other factors that influence health outcomes are inextricably linked to the social categories we belong to, including whether we are male or female; what our age, ethnicity, and sexual orientation is; and whether we are disabled or not. These factors dictate our future too, and they are not so easily changed.

Gender Inequalities

For many women, the gendered experience of being a woman continues to be one of inequality. For example, women have found it difficult to enter some professions because of gender bias. Others have felt trapped in roles that are perceived to be "women's work" (Apter, 1993; Hesse-Biber & Carter, 2000). *The Economist* (2005) reports that women account for fewer than 8% of all CEOs in the United States even though women constitute 46% of the national workforce. This is only very marginally better than the situation a decade ago. Research also confirms a wage gap between men and women. Analysis of U.S. Census data shows that, on average, women's pay is still only 77 cents for every $1 a man earns (Economic Policy Institute, 2005). While this can be partly explained by the kinds of jobs women have and the lower salaries associated with these jobs, this does not explain the entire difference.

Gender also exerts a strong influence on health. Currently, women enjoy a longer average life expectancy than men do. However, once the patterns of illness and disability are examined by gender, the picture is more ambiguous. Although men die earlier than women overall, women experience higher rates of chronic illness at each age. For example, women age 15 years and older account for 60% of all people diagnosed with arthritis (National Center for Health Statistics, 2004). Similarly, depression is nearly twice as common in women as in men. Some of these gender differences are accounted for by biological differences between the sexes; others are related to differences in gender roles. For example, since women live longer than men and have fewer financial resources in retirement (owing to a lifetime of lower wages and less time in the paid labor force as a result of child rearing), women have less money to take care of their health (Collins, Estes, & Bradsher, 2001).

Ethnic Inequalities

Ethnicity significantly affects the life chances of individuals. We use the term *ethnicity* here, rather than *race*, to signal cultural rather than biological explanations for differences in social and economic opportunity. First, and most basically, ethnicity affects educational opportunities. The extent and quality of education are critical factors in life because employment opportunities and thus income are tied to early educational attainment (Miringoff & Miringoff, 1999; Shonkoff & Phillips, 2000). But neither educational opportunities nor the quality of educational experiences is equitably distributed. The U.S. government recognized this fact as early as the 1950s, when it established the Head Start program, a national network of comprehensive child development programs that targeted low-income families and their communities. It should not be that hard to understand that poor minority children are at an educational disadvantage compared with children of wealthier parents from predominantly white families (Young, 1997). Poor children grow up in poor neighborhoods, which have poorer-quality schools, staffed by teachers with fewer resources to enrich the learning environment. Individuals with diminished chances in the early years seldom catch up. This has a particularly dramatic impact on visible minorities, who are more likely to be poor.

Poverty affects health even more than ethnicity does, though the two factors are often found together. Nowhere are the inequalities more clear than in studies of infant mortality. The Population Reference Bureau (2005) publishes data on the infant mortality rates in many countries. These data show that Sweden's infant mortality rate is 3.1 per 1,000 live births, while the U.S. average is 6.6. For black Americans in the United States, however, the figure is a startling 14.4 deaths per 1,000 live births (National Center for Health Statistics, 2004). There are disparities in mortality rates and disease-specific risks too. Census data show, for example, that the prevalence of hypertension is about 40% higher in black Americans than in white Americans, while the prevalence of diabetes is nearly 60% higher in black Americans (National Center for Health Statistics, 2004).

Age Inequalities

Age is another factor that shapes societal opportunity and, in turn, individual health. All societies have some sort of shared cultural expectations of its members based on age. For example, it is commonly accepted that the Japanese treat their elders with more respect and honor than we do in North America. **Ageism** is the term used to describe discrimination based on age (Estes, 2001). Aging is not perceived particularly positively in the United States. Despite substantial research to the contrary, people in the age category we might call "young-old" are often seen as "over the hill." Although it is against the law to discriminate in hiring people, the 60-year-old who wants or needs to find a new job does not find many open doors, regardless of his or her experience. That said, we might see a decrease in ageism as the full impact of the aging Baby Boom generation is felt. Baby Boomers are healthier, wealthier, better educated, and more politically savvy than previous generations were (Soto, 2005). They will likely exert a considerable influence on age-appropriate social roles, including what it means to be "old."

Health and aging are tightly intertwined. Not surprisingly, "age is the single most important predictor of mortality and morbidity" (Weitz, 2004, p. 52). Mortality rates drop dramatically after birth and rise again only at about age 40. Not until age 65 do chronic illnesses overcome acute illnesses as the major cause of death. However, because age and illness are so closely tied, when the average age of the population increases, so does the prevalence of health problems. The proportion of Americans age 65 or older is projected to reach 18% by 2020

(U.S. Administration on Aging, 2005). The health problems associated with aging populations and the financial means to address them are anticipated to be among the biggest health challenges many nations have ever encountered.

Inequalities Due to Disability

Disability is associated with disadvantage, regardless of individual skills or financial resources. In the 2000 Census, disability was defined as a chronic health condition that makes it difficult to perform one or more activities generally considered appropriate for individuals of a given age: play or school for children, work for adults, and basic activities of daily living for the elderly. In 2003, the Census counted 49.7 million people with disability. This represented 19.3% of the population, or 257.2 million people age 5 years and older living in the community (U.S. Census, 2003). The same census revealed employment inequities for people with disability: 79% of working-age men without a disability were employed in 2000, but only 60% of those with a disability were employed. The percentage drops sharply for people with more severe disabilities. Of those with mental disabilities, 41% are employed. For wheelchair users, the figure is 22% (Stoddard, Jans, Ripple, & Kraus, 1998). Medical and technological advances have enabled people to live longer and be more independent, but full social integration and inclusion cannot be achieved without access to schools, jobs, and leisure. The actions at the basis of the Americans with Disabilities Act and earlier legislation reflect the long-standing efforts of the disability rights movement and its allies (including occupational therapy practitioners) to improve life conditions for people with disabilities. Some of the main goals of the disability rights movement are to change attitudes, public policies, and the law (Colker, 2005; Trattner, 1994).

Finally, people with disabilities have poorer health than their able-bodied counterparts. Higher rates of diabetes, depression, elevated blood pressure and blood cholesterol, obesity, and vision and hearing impairments have all been reported (U.S. Department of Health and Human Services, 2000b). Lower rates of recommended health behaviors such as cardiovascular fitness have been found too, as have low rates of patient education and treatment for mental illness.

Because of the intersections of age, ethnicity, and poverty, it is possible to identify specific subgroups of disabled people who are at particular risk. One such group is elderly women living in the inner city, many of whom are minorities. Remember Annie, who lives alone in her home in the inner city after her fall? Lysack and colleagues (2003) found that older urban African-American women who live alone are at increased risk for physical problems, including falls, and cognitive decline, both of which can precede a complete loss of independence and institutionalization. Older adults have also been shown to have less access to specialized rehabilitation services than younger working adults with similar rehabilitation needs (Neufeld & Lysack, 2006). Are occupational therapy practitioners aware of and sufficiently responsive to these particularly disadvantaged groups?

In summary, regardless of our professed beliefs in equal opportunity and despite legislation intended to prevent discrimination, life choices and chances are not equal; they are mediated by an array of powerful social and economic variables that can dramatically dictate the fate of individuals and their health. The foregoing discussion reminds us that these variables are not easily changed or overcome through individual desire and effort. Much larger forces in society, including the health system, play an integral role.

THE POLITICAL ECONOMY OF THE HEALTH CARE SYSTEM

To fully appreciate the influence of socioeconomic factors in individual lives, these factors must be set against the backdrop of the health care system, which has been described as a highly dynamic and fragmented system of competition, regulation, and reimbursement (Shi & Singh, 1998). It is also the most expensive health care system in the world. Health expenditures in the United States in 2004 totaled $1.7 trillion, or 14.6% of gross domestic product, and averaged $5,274 per capita per year (Anderson, Hussey, Frogner, & Waters, 2005).

International Comparisons

Despite the huge amount spent on medical care, the United States ranks low on many health indicators (World Health Organization, 2005), and there is mounting evidence that the system is plagued with serious problems at all levels (Moss, 2000; Rylko-Bauer & Farmer, 2002). Life expectancy in the United States stands at 77.2 years, below the average of 77.8 years for the 30 developed countries that belong to the Organization for Economic Cooperation and Development (OECD, 2005). This lags behind countries such as Poland, Korea, and Mexico. Infant mortality rates, too, though they have fallen greatly over the past few decades, have not fallen as much as the rates in most other OECD countries. Infant mortality stood at 7 deaths per 1,000 live births in 2002, above the OECD average of 6.1 and well behind countries such as Japan, Iceland, Finland, and Sweden. As citizens of one of the richest countries in the world, Americans have a right to expect better health (Whiteis, 2000).

The Role of Health Insurance

Health insurance (or, more accurately, medical insurance) is important because access to health care in the mostly

private U.S. system requires either a job with health benefits or the financial means to pay out of pocket. A substantial number of Americans lack both. Nearly 45 million Americans are estimated to have no health insurance, and another 52 million are thought to have insufficient coverage (Brouwer, 1998; Cutler, 2004). Minorities make up a disproportionate part of the uninsured: Blacks are twice as likely as whites and Hispanics are three times as likely as whites to be uninsured because of type of employment and lower income (Centers for Disease Control and Prevention, 2003). Insurance matters because the uninsured and underinsured have reduced access and less appropriate care, are in poorer health, and are more likely to die prematurely (DeNavas-Walt, Proctor, & Lee, 2005; Institute of Medicine, 2002; Krieger, 1999).

The health disadvantage associated with lack of health insurance is not only a poor person's problem. The Kaiser Family Foundation (2003) found that over half of all uninsured workers in the United States in 2002 worked full-time that year. The problem is increasing because fewer middle-class jobs are coming with employer-sponsored health benefits (Lee, Soffel, & Luft, 1994; Shi & Singh, 1998). A recent *New York Times* series showed just how hard the middle class is being squeezed by factory closures, layoffs, and large-scale economic downturns (Scott, 2005). This is linked to health. For example, in 2003, more than 27 million working adults had medical debt, yet only 62% of those had health insurance (Doty, Edwards, & Holmgren, 2005).

In programs in which people have health insurance paid for by the government, such as Medicare and Medicaid, the impact of out-of-pocket expenses can still be significant. Researchers at the American Association of Retired Persons (Caplan & Brangan, 2004) found that Medicare beneficiaries (age 65+) spent an average of $3,455, or 22% of their income, on unreimbursed health care. The largest cost was prescription drugs. The situation is even worse for uninsured workers with chronic conditions. Nearly half of the total of 6.6 million uninsured chronically ill Americans report medical bill problems, making them much more likely to forgo or delay needed medical care (Ha, 2004). This is leading to major hardships for many. A study found that 28.3% of all personal bankruptcies in the United States today are substantially caused by illness or injury; the comparable rate in Canada is lower than 7% (Himmelstein, Warren, Thorne, & Woolhandler, 2005).

There is no question that Americans need to care about the uninsured and rising costs of health care, whether on the basis of social justice or simply as a matter of dollars and cents. Kawachi and Berkman (2003) warn that the least fortunate in society must be cared for, or spillover effects will adversely affect everyone. Wide income disparities lead to stress, family disruption, and mass frustration, which in turn lead to violence and crime. According to Lynch and colleagues (1998), if this trend is left unchecked, the economic prosperity of the nation could be permanently compromised.

MECHANISMS OF DISADVANTAGE ACROSS THE LIFE COURSE

There is an untested assumption that disparities in health arise from disparities in health care. Of course, there is a gap in this logic: The fact that there are defects in a medical system does not mean that the system caused the problems. So why are there differences in health status across different groups in society? Part of the problem is poverty and income inequality.

Money Matters: Economic Deprivation and Health

Poverty is bad for health. The term *poverty* refers to the lack of material resources that are necessary for subsistence. Poverty increases exposure to factors that make people sick, and it decreases the chances of having high-quality medical insurance (and thus care) when the person needs it. Children, older adults, new immigrants, disabled people, and members of ethnic minorities are at greatest risk of poverty (U.S. Census, 2003). Perhaps most alarming is the fact that the official poverty rate in the United States increased in each of the last four consecutive years that were measured, from a 26-year low of 11.3% in 2000 to 12.7% in 2004. As of 2004, 37 million Americans lived below the official poverty threshold (U.S. Census, 2005).

Economics and health policy experts are asking whether pronounced levels of income inequality take a lasting toll on other aspects of people's lives, not just health. A report published in the *New York Times* in 2003 (Browning, 2003) pointed out that the richest 1% of Americans in 2000 had more money to spend after taxes than the bottom 40% put together. That's roughly three million people outearning 110 million—a rather staggering figure. Perhaps this has fueled the entry of two new terms into the popular lexicon: *the working poor* and *the new poor.* The **working poor** are people who work full-time but whose wages do not raise them above the poverty line. Nearly 6% of U.S. workers currently earn the federal minimum wage of $5.15 an hour (U.S. Department of Labor, 2005). Based on a 40-hour week, this provides an annual income of $10,700. Many critics have asked how the working poor even get by (Ehrenreich, 2001; Shipler, 2005; Wilson, 1997). The **new poor** are those people who have fallen into poverty because of sudden and unexpected circumstances such as serious illness, divorce, or sudden job layoffs. Sidel (1996) describes the situation of one woman who, after 23 years of marriage, was divorced by her husband. When he left the state and refused to pay child support, the family's annual income fell from

$70,000 to $7,000. Her part-time job was not enough to keep her out of poverty.

The working poor and the new poor stand in sharp contrast to the wealthiest individuals in the United States. Did you know that the average CEO's pay in the United States is $11.8 million? Since the average American worker earns only $27,460 per year, this is an astounding 431-to-1 ratio (Institute for Policy Studies and United for a Fair Economy, 2005). Recall Annie's struggle to regain her mobility after her hip fracture and how she must rely on limited financial and medical resources (see Figure 7.1). Will Annie join the ranks of the new poor? What affordable suggestions would you give Annie if you were her occupational therapist? What kinds of barriers should you anticipate as Annie tries to implement your recommendations?

The case study about Annie that opened this chapter reminds us that money matters in efforts to achieve good health. But money is not the only thing. A variety of other factors matter too. In a set of famous studies commonly referred to as the Whitehall studies, Marmot, Shipley, and Rose (1984) studied British civil servants over three decades to ascertain more precisely how one's place in the occupational hierarchy influences health. Because occupation is shaped by both economic circumstances and other factors in the social environment, this turned out to be highly influential research. Results of the Whitehall studies showed that men in the lowest levels of the civil service, office support workers, had a mortality rate four times greater than that of men in the highest administrative jobs. The findings were consistent across the spectrum of job categories. Being on the top rung was clearly best for your health, but every step closer to the top mattered too (i.e., the social gradient). This work and studies that followed laid the groundwork for an entire new branch of epidemiology called the **social determinants of health**. Today, it is widely accepted that whatever the importance of biological and genetic factors and even personal lifestyle factors and access to health care, the social and physical environment is of tremendous significance too.

Proponents of a social determinants perspective argue that the mechanism by which health is adversely affected is through physiological stress. The lower people are in the social hierarchy, the more common and pronounced are their stress-related problems. The disadvantages concentrate among the same people, and the effects of these disadvantages on health are cumulative (Lynch et al., 1998). Simply put, the longer people live in stressful social and economic circumstances, the greater is their physiological wear and tear and the less likely they are to enjoy a healthy old age. The implications of this are tremendous. Most basically, it means that "fixing" the health care system by addressing disparities in treatment is only part of the solution. If we really wish to improve the health of those who are most disadvantaged in society, we must work to reduce various forms of social inequalities and social

FIGURE 7.1 Many older women living in the inner city lack financial resources to modify their homes to improve safety and independence. What can feasibly be done at low cost to facilitate community mobility and participation in this group? (Source: Lee Ann Johnson, photographer, Wayne State University, Detroit, used with permission.)

deprivation that exist in society. This would need to begin in early childhood and continue throughout life.

Deprivation Across the Life Course

A plethora of observational research and intervention studies show that the foundations of adult health are laid in early childhood, even before birth (Brown et al., 2004; Young, 1997). This combination of a poor start and slow growth "become embedded in biology during the processes of development, and form the basis of the individual's biological and human capital, which affects health throughout life" (Wilkinson & Marmot, 2003, p. 14). Studies have demonstrated that as cognitive, emotional, and sensory inputs program the brain's responses, insecure emotional attachment and poor stimulation can lead to low educational attainment, problem behavior, and the risk of social marginalization in adulthood (Barker, 1998). Slow physi-

cal growth in infancy is also associated with reduced cardiovascular, respiratory, pancreatic, and kidney function, which increases the risk of serious illness in adulthood (Shonkoff & Phillips, 2000).

Children also learn and develop through play. Not only does play help them to learn about themselves as individuals, it also helps them to acquire their fundamental socialization skills and many motor and cognitive skills. Kozol (1991, 1995) describes neighborhoods overrun by poverty, crime, and economic neglect. In such neighborhoods, parents are afraid to let their children play outdoors because of high rates of violence and heightened exposure to environmental toxins, injuries, and disease (Kozol, 1991, 1995). The cumulative damage is such that some argue that no amount of therapy and treatment can undo the consequences (Brown et al., 2004).

Social inequalities over the life course also contribute to deprivation in adults. This occurs primarily in the realm of work. While work is in many ways a marker of good health, work can also be the source of poor health. Anxiety, substance abuse, and depression rates are all higher in populations in which unemployment is high (Lawrence, Chau, & Lennon, 2004). For those who are employed, there are other stress-related problems; research has shown that lack of personal autonomy and control in one's work is significantly related to cardiovascular disease (Bosma, Peter, Siegrist, & Marmot, 1998). The mechanism for this appears to be related to excessive production of cortisol or "stress hormones." Beyond the workplace, the news for workers is hardly better: leisure time is decreasing. A recent international travel survey by Expedia.com (2005) found that Americans work the most hours of any affluent country. Americans earn an average of 12 vacation days annually, lagging behind Canada with 21 days and Germany and France with 27 and 39 vacation days, respectively. Even so, 31% of Americans do not take all of their accrued annual vacation time, with 10% saying they are "too busy at work" to get away.

OCCUPATIONAL THERAPY SERVICES: ARE WE EQUITABLE? ARE WE RESPONSIVE?

Townsend and Wilcock (2003) asserted that it is an occupational injustice to ignore the social and economic determinants of health. Others have called on occupational therapists to address the segregation of groups of people based on lack of meaningful participation in daily life occupations, something that Kronenberg and Pollard (2005) have provocatively called **occupational apartheid**. There is little doubt that socioeconomic factors are real and exert a powerful influence on health, but what is the average occupational therapist to do in the face of what appear to be intractable problems on a very large scale? Even if we develop greater awareness of the influence of social in-

equalities on health and the extent of health disparities in the clients we serve, what are the next practical steps?

First, we can apply the small but growing body of evidence we have from occupational therapy research that focused interventions can bring meaningful benefits. For example, occupational therapy with children can effectively address sensory motor performance deficits (Case-Smith, 2002), peer play relationships (Tanta, Dietz, White, & Billingsley, 2005), and family interactions (Bedell, Cohn, & Dumas, 2005), which all may be more prevalent in socioeconomically disadvantaged families. Occupational therapists can also support parents to better understand their children's emotional and cognitive needs and modify school and home environments to facilitate occupational performance (Letts, Rigby, & Stewart, 2003). Occupational therapists working in gerontology can help to design supportive environments for older adults that facilitate aging in place.

Occupational therapists are experts at person-environment fit and recognize the centrality of meaningful occupations to facilitate good health. Yet there are serious gaps in our knowledge. For example, we know very little about meaningful occupational engagement for chronically unemployed people and what kinds of interventions might be effective for them. We know even less about occupational deprivation due to immigration, geographical isolation, and incarceration (Whiteford, 2000). Much more research is needed if we expect to extend beneficial therapeutic interventions to these groups of people, who might be the most occupationally disadvantaged of all.

A second concrete and immediate step we can take is to move past an all-too-pervasive "occupational hazard" in occupational therapy, which is to think of our clients in depersonalized categories and our practice as politically neutral. With respect to the first issue, we tend to treat "a really interesting traumatic brain injury" or complain about "an old stroke that has plateaued." These phrases are shorthand abstractions of what we really intend to offer in the occupational therapy process. We like to say that one of the unique strengths of the profession is our holistic approach. That phrase does not simply mean that we address the physical and psychosocial domains in our therapeutic goals with our clients. It means that we have to learn about our clients just like Annie, in the terms of her world, her perceptions, her experiences, and her realities. This is easy to say and much more difficult to do. Purtilo and Haddad (2002) describe many difficulties that arise between practitioners and clients because of socioeconomic and cultural differences. These differences influence how we feel about our clients, including the degree to which we empathize with them and even understand their daily routines.

Occupational therapy practice is not value-neutral. Socioeconomic and cultural differences affect practice in very real ways on a daily basis. Fitzgerald, Williamson, Russell, and Manor (2005) describe the dilemmas ther-

apists encounter as they try to balance their professional concern and protection of clients with the wishes clients express for themselves. In reviewing these dilemmas, the investigators reported that while every occupational therapist "wants to wear a cloak of competence" and "wants others to see it as fine and good" (p. 344), there is no denying the force of moral judgments in their work. Therapists cannot help but be shaped by the prevailing cultural attitudes of their times and they would be remiss not to recognize how these attitudes and values, at times, operate to further disadvantage their clients. At minimum, this research reminds occupational therapists of the fundamental importance of critical reflective practice.

Third, to be able to act on issues of occupational deprivation and occupational injustice requires that therapists become much more educated about socioeconomic barriers to treatment and optimal health outcomes. More than a decade ago, Dunn, Brown, and McGuigan (1994) referred to the need to consider the effect of context and questioned whether "standardized functional assessments are valid for capturing what is actually known about the person's performance in the natural context" (p. 605). The context to which these authors referred was the home and community context. But context can be extended further to include the adequacy of neighborhoods and communities to provide a safe and secure living environment, the accessibility of transportation and housing, and even the availability of work for individuals with disabilities. Do we routinely use or even have appropriate assessments of neighborhood safety and community mobility? What about measures of the adequacy of public housing and transit for patients who are discharged home? Are occupational therapists prepared to expand their scope of practice into the social and economic environment, even if reimbursement issues can be overcome?

Another issue is the financial ability of our clients to implement actions aimed at enhancing their independence and participation in daily life. In a study focused on home modification recommendations, Lysack and Neufeld (2003) found that patients who relied solely on Medicaid and Medicare received fewer recommendations from their occupational therapists than did privately insured patients, even when their health conditions were similar. Mathieson, Kronenfeld, and Keith (2002) found that having supplemental health insurance acted as an enabling factor with respect to using equipment and implementing home modification recommendations. Taken together, studies like these suggest that clients who lack the ability to pay or even are perceived to lack the ability to pay may lose out. Their functional independence and even their participation in society may be compromised as a result. More research is needed to determine how prevalent these practices are and how important a factor income really is in determining rehabilitation outcomes over time. This work is urgently needed if we wish to understand the socioeconomic dis-

advantage that some of our clients confront every day and to identify effective pathways of redress.

In addition to being evidence-based practitioners who identify and use new assessments that tap into the socioeconomic realities of clients more deeply, occupational therapists can leverage their position within the health care system to help reduce the impact of socioeconomic disadvantage. For example, therapists can enlighten insurance payers about the needs of their low-income clients by listing occupational therapy services recommended as the ideal for their clients alongside the documentation required for services currently eligible for reimbursement. This kind of documentation practice keeps the gaps between the ideal and the real in the forefront of the minds of decision makers who have the power to affect wider change.

Lohman and Brown (1997) addressed the issue of therapists' ethical obligations and moral stance in the context of managed care and urged clinicians to vigorously represent and advocate for patients—not only in direct service situations, but also at policy levels. Many occupational therapists working in inner-city environments already pursue alternative modes of funding to implement home safety recommendations (Pynoos, Tabbarah, Angelelli, & Demiere, 1998). Another strategy is to employ the specific rules and language of insurance companies much more strategically so that occupational therapy interventions have the best chance of being accepted by payers (Uili & Wood, 1995). Efforts like this take commitment and persistence, but these efforts can be effective—and not only for a single client around a single issue. A successful change in policy can benefit thousands if not tens of thousands of clients, making these efforts more than worthwhile.

CONCLUSION

The majority of health care professionals would say that they learned their most important lessons from their clients. These stories are usually about how the professional lacked an understanding of the situation and how the client set the professional straight about how things really were. This means that we have to listen, and we have to ask the right questions and give the time and space for the answers (Law, 1998; Lawlor, 2003; Wood, 1996). But while listening to and learning from individual clients are paramount to effective occupational therapy interventions, we must remember that this approach individualizes the underlying problems of health disparities and inequalities that are fundamentally social in nature. Occupational therapists who work with socioeconomically disadvantaged clients are well acquainted with this tension. And while some experts have argued that the path forward lies in large-scale professional coalitions aimed at major transformations of the health care system (Cutler, 2004), this takes time to achieve, if it can be achieved at all. In the

meantime, occupational therapists must work in a system that is imperfect, knowing full well that it does not meet many of their clients' pressing needs.

Recall once more Annie's struggle to recover from a lifetime of social and economic disadvantage. There are many Annies in occupational therapy practice, and you will likely meet more than one. To accomplish the true promise of occupational therapy undoubtedly requires better knowledge of the communities from which our clients come and the socioeconomic and historical and political forces that have shaped their lives and their health. The onus is on us to identify inequalities and disparities where they exist and work to ameliorate them. This is the only way to advance health for all.

The Meaning of Place

GRAHAM D. ROWLES

Learning Objectives

After reading this chapter, you will be able to:

1. Identify, define, and explain the dimensions of a person's relationship with environment and the phenomenon of being in place.
2. Describe and explain life course–related changes in the manner in which people experience their environment as they progress from infancy to old age.
3. Explain the role of the physical environment and personal artifacts in defining and sustaining the self.
4. Describe the primary effects of environmental change and relocation and explain the mechanisms that individuals use to accommodate to environmental change and reestablish themselves in new environments.
5. Understand and explain the critical significance of an understanding of environment and place for effective occupational therapy practice.

THE PERSON-ENVIRONMENT RELATIONSHIP IN OCCUPATIONAL THERAPY

Place in Human Experience

Increased recognition of the role of the environment in conditioning human experience began to permeate occupational therapy during the 1980s (Barris, 1986; Barris, Kielhofner, Levine, & Neville, 1985; Kiernat, 1982, 1987). It is now widely acknowledged that full understanding of a person cannot be achieved independently of an appreciation of environmental context—the place where the person dwells. Occupational therapists have proposed several theories of the person-environment relationship that emphasize this interdependence (Christiansen & Baum, 1997; Dunn, Brown, & McGuigan, 1994; Kielhofner, 1995; Law et al., 1996; Schkade & Schultz, 1992). These transactional theories, as well as more recent ascendant perspectives that focus on the phenomenology of "being in place" (Rowles, 1991, 2000), "physical comminglings" (Seamon, 2002), and holistic Deweyan perspectives on "place integration" (Cutchin, 2004; Dickie, Cutchin, & Humphry, 2006), represent a shift from simple sequential stimulus-response conceptualizations of the individual as influenced by the environment or the environment as modified by human action. We are now moving toward directly acknowledging the degree to which the relation-

ship involves blending person and place in human experience. Indeed, it is now widely accepted that the self evolves through activity that is in and of rather than being separate from the environment and that lives are intimately and inextricably defined by and immersed in place.

There is also increasing recognition that each person's relationship with environment cannot be considered independent of its historical context and the accumulation of experiences of place over time (Settersten, 1999, 2003; Wheeler, 1995). Each person is born in a particular location, into a particular family configuration, into a particular culture, and into a specific birth cohort. Over the course of life, each individual is molded by experience—a melding of physiological capability, individual agency, and circumstance—in a manner that profoundly influences the person he or she becomes (Jonsson, Josephson, & Kielhofner, 2000).

Phenomenological Perspective

Effective occupational therapy practice requires more than cursory inspection of a physical setting and compilation of a brief personal history. Probing deeper, it is important to understand each person from the perspective of an experienced context—the life world within which he or she defines the self, conducts daily activities, and receives occupational therapy intervention. From such a phenomenological perspective, how does the person experience his or her world? To what extent has the person created the physical setting of home, with its familiar furniture, memorabilia, and photographs, as an expression of self, perhaps over the course of decades (Rowles & Chaudhury, 2005)? To what extent is the person continuing to manipulate the setting to accommodate changing needs and abilities in ways that facilitate maintaining a sense of self, agency, and a meaningful life? Alternatively, in what ways is the person a prisoner of space, constrained by the configuration and accoutrements of the setting and trapped in a place that is increasingly confining and restrictive? In essence, what is the meaning of dwelling in a particular place and what are the implications of this meaning for the practice of occupational therapy? To answer such questions, it is important to understand complex dimensions of meaning that characterize the phenomenon of dwelling and that nurture a therapeutically desirable sense of being in place (Rowles, 1991, 2000).

BOX 8.1 DIMENSIONS OF BEING IN PLACE

Use of Space

- Immediate physical activity: Range of motion and functional capability-related movement in the proximal environment.
- Everyday activity: Routine and often repeated daily trips along familiar pathways involved in the conduct of daily life.
- Occasional trips: Vacations and long-distance trips, generally involving overnight stays.

Orientation in Space

- Personal schema: A physiologically based axial orientation that enables the individual to maintain balance and distinguish left from right, front from back, and up from down.
- Specific schemata: Cognitive linear maps of regularly traveled pathways including an awareness of environmental cues that facilitate successfully traversing these pathways.
- General schema: An implicit cognitive map of the world as known, which can be evoked and mentally constituted at diverse scales and in diverse manifestations that vary according to the circumstances in which it is invoked.

Emotional Affiliations with Place

- Personal: Emotions evoked by personal experiences within particular locations that imbue settings with meaning and significance for the individual (may be positive or negative).
- Shared: Mutually developed emotions for place developed and refined through interaction over time among residents of a shared environment or through shared experience of an environment.

Vicarious Participation in Spatially and/or Temporally Displaced Environments

- Reflective: Involvement in places of one's past (either the current environment as it was in the past or previously experienced places located elsewhere).
- Projective: Vicarious projection into contemporary places that are geographically separated from the individual's current location.

Relevance to Occupational Therapy

Developing a sense of environmental, life course, and phenomenological context and blending this sense within a holistic understanding of each person's situation is of paramount importance to practitioners because occupational therapy interventions are invariably framed within a unique set of social and environmental circumstances (Gitlin, Corcoran, & Leinmiller-Eckhardt, 1995) and against the backdrop of a person's integration of these circumstances within a unique sense of self and of being in place. Interventions that take an individual out of place—for example, those that involve radical reconfiguration of the residence (e.g., significant rearrangement of furniture) or those that occur in a hospital, clinic, or rehabilitation environment—are invariably compromised because the person's agenda is necessarily expanded to cope with accommodation to a new and unfamiliar setting. In some cases, treatment in a hospital or clinical setting is inevitable because of the availability of specialized equipment and personnel. This does not obviate the need for understanding the dimensions of a person's being in place. Rather, it makes such understanding even more important in order to design treatment settings that create a level of environmental comfort that is conducive to effective occupational therapy practice.

DIMENSIONS OF BEING IN PLACE

A person's sense of being in place is a complex and dynamic phenomenon (Rowles, 1978, 1991, 2000; Rubinstein & Parmalee, 1992; Tuan, 1977). Several underlying themes or dimensions can be identified, as described in Box 8.1.

Using Space

At its most fundamental and easily observable level, being in place involves patterns of activity in using space. Space is utilized on multiple levels. First is the domain of immediate physical activity or range of motion. This involves activities of daily living, such as the functional ability to reach for a high shelf or to crouch without difficulty to don socks or tie shoelaces. Use of space on this level becomes a primary focus of occupational therapy when activity becomes limited through illness or accident and basic movement is impaired.

On a larger scale, we traverse the physical environment and trace regular pathways of everyday activity that over time become habitual (Rowles, 1978, 2000; Seamon, 1980). Each weekday morning, we walk to the corner of our street to catch the bus to work. On Sundays we drive a familiar route to church. Over time, we tend to develop a regular time-space rhythm and routine in use of the physical environment that becomes taken for granted and subconscious as our body adapts to the setting (Figure 8.1). Occupational therapy research suggests that deeper understanding of habits and habituation might hold the key to important therapeutic interventions (American Occupational Therapy Foundation, 2000, 2002).

The regular routine of everyday behaviors is enriched or disrupted by occasional trips that take us beyond our daily round. We vacation in a distant state or make an annual visit to stay with a relative. After an automobile accident, we might spend a period recuperating in a rehabilitation hospital some distance from our home.

Over the life course, patterns of using space gradually evolve in concert with changing capabilities and resources.

FIGURE 8.1   The everyday habit of breakfast at a local eatery forms important relationships. (Courtesy of D. Prince, University of New Hampshire Photographic Services, Durham, NH.)

The infant is restricted to a crib or playpen. The child, under a parent or sibling's watchful eye, might be permitted to play in the yard or in the neighborhood. Access to a first automobile significantly increases spatial range and in adulthood might lead to increased propensity to roam far and wide. With advancing years, the space within which we physically reside and travel might become limited once again as we become environmentally vulnerable.

Patterns of using space are closely intertwined with the manner in which we cognitively orient ourselves in the environment. This involves a physiological orientation within the axial system of the human body that provides the ability to discriminate up from down, left from right, and front from back. This personal schema is taken for granted. Its critical role might be fully recognized only when we become disoriented through a health condition such as Meniere's disease, excessive consumption of alcohol, or the secondary effects of medication.

Physiologic orientation is a necessary but not sufficient condition for moving around in the environment. We must also develop mental images, that is, cognitive maps of the configuration of the environment that guide us as we traverse space (Downs & Stea, 1973). Over time, we develop detailed cognitive awareness of paths we trace each day. This awareness may involve an array of environmental cues, comprising specific schemata that mark each route we take: The more familiar the journey, the more implicit are the schemata. The first time we walk an unfamiliar route, we are acutely aware of directions and environmental cues that mark the places to turn or to cross the street. As we repeatedly pass along this way, the need to use these cues recedes into the subconscious.

Cognitive awareness of regular pathways is embedded within a general schema. This implicit cognitive map of the world as we know it is characteristically centered on our residence. It involves detailed awareness of zones of immediately adjacent space, for example, the surveillance zone—the area within the visual field in which we may develop strong visual or mutually supportive relationships with neighbors characterized by a high level of everyday reciprocity (Rowles, 1981) (Fig. 8.2). We may also be familiar with space beyond the visual field, which becomes identified as our neighborhood. As we move farther away from home, cognitive awareness of space becomes progressively more fragmented and sketchier. There may be limited cognitive knowledge of the configuration of spaces beyond our own community, city, or town. The exception is a limited number of "beyond spaces." These are places we have visited on occasional trips, settings where we lived in the past, or familiar places where relatives reside. We might retain detailed images of the configuration of such noncontiguous places despite lack of everyday exposure.

Life course transitions in the use of space are paralleled by evolution in the manner in which we orient ourselves within space. In childhood, the imaged environment might be limited to our home and surroundings in the immediate vicinity. As experience increases and we become geographically liberated, our cognitive world becomes more extensive. A cosmopolitan mobile pattern of life in adulthood may lead to familiarity with environments throughout the world and an acute sense of their configuration and spatial relationship to one another. If we lead a life that is focused on a single urban neighborhood or rural community, our orientation might be equally rich and detailed but more locally focused. Finally, as we grow older, the tricks of memory and the sheer volume of accumulated place experiences can result in complex overlapping cogni-

FIGURE 8.2   The surveillance zone. (Courtesy of G. Rowles.)

tive images within which specific locations may be known simultaneously as they were during a series of different times in their existence. Our awareness of a less frequently visited location might be a residual memory of its past rather than an accurate image of its current configuration.

Meaning in Place

Patterns of use and cognitive orientation to place parallel the development and reinforcement of distinctive place-related emotions (Altman & Low, 1992; Seamon, 1984). Some of these are individual and highly personal meanings. They may express a sense of affinity with places where key life events transpired—where we first met our future spouse, made love for the first time, or experienced a traumatic event. Mere presence in such places can evoke memories, the resurrection in consciousness of key incidents in our lives, and strong visceral emotions. As life experiences accumulate, frequently inhabited places where multiple events occurred over an extended period of time become suffused with an array of emotions that reflect a place biography of self and setting (Cattell, 2005).

Other place-related emotions reflect shared meanings. They arise from common habitation of a space—for example, an inner-city neighborhood or residential suburb—by a cohort of residents who, through their interaction and shared experiences, gradually come to imbue the place with its own personality, identity, and meanings as a social space (Després & Lord, 2005; Peace, Holland, & Kellaher, 2005; Rowles, 1978; Suttles, 1969). Long-time residents of changing neighborhoods may share complex emotional identification with a collage of the many different places it has been over the course of their lives, ranging from vibrant new development to rundown and largely abandoned slum.

Recognition of the critical role of time in human experience allows us to understand being in place as far more than the physical occupation of a space, the use of orientation skills, and the development of emotional affiliation with particular locales. Through the uniquely human capacity to remember, to imagine, and to project ourselves mentally into spaces beyond our immediate visual field, we can vicariously participate in spaces that have been displaced in space and time. We can return in our minds to the places of our childhood through a process of reflective vicarious reimmersion (Chaudhury, 1999). We can also engage in projective vicarious participation within the contemporary environments of family members and imagine what they might be doing half a continent away as we watch a televised national weather forecast that informs us that it is raining where they live (Rowles, 1978).

The ability to traverse space and time in our mind and inhabit an experiential world that is much larger than the immediate and contemporary physical setting is nurtured and reinforced by the artifacts with which we surround ourselves. Particular items of furniture, treasured per-

sonal possessions, scrapbooks, and photographs all serve as cues to the resurrection or stimulation of place experience in consciousness (Belk, 1992; Boschetti, 1995; Sherman & Dacher, 2005). Such items convey a sense of identity, capture essential elements of our autobiography, and, in so doing, help us to define and maintain a sense of self. We become the places of our lives—where we live and what we own.

To summarize, the spaces of our life become transformed into the places of our life through a variety of physical, cognitive, emotional, and imaginative processes of habitation that imbue existence with meaning and personal significance. Contemporary physical presence is only a small part of being in place. It is merely the overtly observable and most readily apparent aspect of a complex self that has gradually evolved over the life course, with the accumulation and integration of a plethora of life-shaping and person-forming experiences in the different places we have occupied from birth until the present.

Meaning of Home

The most intense expression of being in place characteristically involves our relationship with home—usually, although not invariably, the dwelling where we reside. In this location, we find the most sophisticated expressions of human relationship with the environment with respect to all levels of being in place: use, cognitive orientation, emotional affiliation, and vicarious involvement (Marcus, 1995; Rowles & Chaudhury, 2005; Rubinstein, 1989; Sixsmith, 1986; Zingmark, Norberg, & Sandman, 1995). Indeed, being in place entails being "at home."

Home is territory—a place of possession and ownership that may be fiercely defended. Home is a place of privacy, safety, and security. Often, home is the spatial fulcrum of our life, a place of comfort and centering that may become the core of our being and a location from which we venture forth into a potentially hostile world outside and beyond and to which we return for shelter. Home is a place of freedom, a location where we can let go and be ourselves. Home is a repository of the items we have accumulated that catalogue our history and define who we are. Beyond the personal significances with which such items can be imbued, home often also becomes a locus of expression as we present ourselves to visitors, neighbors, and those who pass by, through the way in which we maintain and decorate the property and care for our yard.

Because of the complex interweaving of these themes over an extended period of residence, home may come to be viewed as a sacred place and the seat of a person's very being and identity (Eliade, 1959; Rowles, 2006). For many people, to abandon one's home is not only to become homeless and placeless (Hasselkus, 2002; Relph, 1976; Watkins & Hosier, 2005), but also, in a quite literal sense, to experience a severance from self.

MAKING SPACES INTO PLACES OVER THE LIFE COURSE

Being in place and its relationship to self is a dynamic phenomenon. Throughout the life course, as we move from location to location, we are constantly creating and recreating place as a component of personal identity. With every move, we slough off elements of our past. With every move, we carry selected elements of this past with us and meld them with new experiences and the influence of new environments in creating a contemporary lifestyle and sense of being in place in the present. This selective process of transference allows us to maintain a continuity of self and identity that is reinforced by an evolving relationship with the places of our life (Rowles & Watkins, 2003; Twigger-Ross & Uzzell, 1996).

Transitions and Disruptions of Being in Place

A variety of circumstances result in changes in an individual's relationship with place that have important consequences for sense of self and well-being. Among the most profound are changes in personal capability. During the first portion of life, such changes are generally liberating. As we progress from infancy through childhood and into adolescence, the geographical world tends to expand as physical and mental capabilities develop and access is gained to an ever-wider array of resources (education, income, transportation). Competence tends to increase within an increasingly diverse array of environments. At the other end of the life course, as we grow old, physical and sensory decrements may become restrictive and confining, at least with respect to our physical use of space. It might become more difficult to venture abroad, to maintain our home, even to climb the stairs to an upstairs bedroom.

Lives are also lived within the context of constantly changing environments. New roadways slice disruptively through neighborhoods, the physical landscape changes with the addition of new buildings or the deterioration and demolition of old ones, new populations migrate into formerly stable residential enclaves, and both natural and human-made disasters transform the landscapes of our life. In youth, such change might be a source of stimulation and new opportunity; but as we grow older, we might become less resilient in accommodating to external environmental changes. Regardless of its source, change in people's relationship with the environment, whether in situ change or relocation, has become a predominant motif of life in contemporary Western societies.

Creating and Recreating Place

A fundamental human tension exists between the need for familiarity, security, and a sense of continuity and an urge to explore and to venture forth into the unknown (Balint, 1955; Buttimer, 1980). This tension is expressed in sequential habitation of the environments of our life through processes whereby we constantly create and recreate place as an expression of an evolving self (Rowles & Watkins, 2003). Most people exhibit residential inertia and reluctance to move. The intensity of this inertia may vary over the life course and among different generations; many young people exhibit greater enthusiasm for relocation, and many elders express a desire to age in place (Callahan, 1992; Tilson, 1990). When relocation does occur, there are certain constancies in the manner in which people accommodate to change.

People who have a history of frequent relocation often become experienced place-makers. With every relocation, they become more adept at sustaining links with places of their past even as they accommodate to opportunities provided by new settings. The process involves several overlapping elements, and each serves to preserve a continuity of self. First, there is a tendency for "holding on," which is manifest in routine ways of accommodating to the stress of separation from environments of our past. Contact with previous settings may be maintained through periodic return visits, telephone calls to former neighbors, or maintaining ongoing correspondence. Maintaining links with the places and the self of the past may also involve transferring treasured artifacts, including photographs and memorabilia, that serve as cues to key events and locations in personal history (Boschetti, 1995; Paton & Cram, 1992).

A second element of creating and recreating place is a recurring process of "moving on"—personal growth through active investment in each new setting (Leith, 2006). Often, this involves lifestyle change as a result of accommodation to illness, disability, or other changed circumstances. The process may involve the use of learned strategies for making new friends and becoming involved in the local social milieu such as making conscious efforts to visit new neighbors or coresidents (Reed & Payton, 1996). It may entail efforts, sometimes subconscious, to recreate elements of the familiar in each new setting. For example, some people facilitate maintaining a comfortable routine in the use of space by arranging their furniture in a configuration similar to that which existed in their previous residence (Hartwigsen, 1987; Toyama, 1988). Re-creation of place may also involve the selective transfer of artifacts and possessions and their arrangement within a new space in ways that serve to define and reinforce an evolving sense of self (Belk, 1992; Boschetti, 1995). Finally, moving on may involve a determined, conscious and adaptive phenomenological reformulation of the meaning of home through an ongoing process of merging lifelong expectations and experiences of previous places of residence with the potentialities and limitations of each new environment "thereby creating an essence of home that is at once old and new" (Leith, 2006, p.331).

Creating and recreating place is a lifelong process. During the first part of life, processes of accumulation tend to be dominant. Thus, a student apartment gives way to the condominium of the young professional, the first single-family home, and a series of progressively larger dwellings in parallel with changing needs as we find a partner and establish a family. We tend to accumulate more and more possessions—possessions that can come to define our persona. As we grow older, in many cases, we are obliged to move from spacious dwellings to residences with progressively less space. This process may gradually give way to processes of household disbandment and divestiture that involve a carefully reasoned but often emotionally taxing reduction of inventory (Eckerdt, Sergeant, Dingel, & Bowen, 2004; Morris, 1992). A priority may be placed on retaining items of particular personal and self-defining significance while selectively giving other items to children and others in the process of establishing a legacy that will allow aspects of the self to endure after death (Hunter, 2005). For elders, a continuing sense of being in place may be closely related to the ability to accomplish these processes in a manner that facilitates the retention of ongoing identity.

THE PLACE OF PLACE IN OCCUPATIONAL THERAPY

This chapter suggests that understanding a person's sense of self and well-being is intimately linked to a phenomenological life course–based understanding of an evolving person-environment transaction. Within this rubric, the definition of *person* has been expanded to emphasize the role of autobiography in defining the self. The concept of environment is elaborated and recast as the experiential notion of place. This reconfiguration is more than semantic novelty. Rather, it provides the basis for deeper understanding of human "being in the environment as a whole" aspects of the experienced world of the client that have important implications for practice (Dickie, Cutchin, & Humphry, 2006).

At the most fundamental level, there is a need for occupational therapy practitioners to become more intimately attuned and sensitive to the complexity of each client's being in place. It is not enough solely to observe a person's contemporary architectural setting and identify the physical barriers that interfere with performance of daily occupational tasks. Admittedly, it is important for practitioners to become advocates for client-centered environmental design that enhances occupational performance through design modification and the use of assistive devices. While this might be necessary as a first step in seeking interventions to improve functional performance, it is not sufficient if the goal is to enable the client to realize his or her full potential for attaining the highest possible quality of life. To accomplish this more sophisticated objective, it is necessary to embrace a broader understanding of place as a component of therapy—to develop place therapy (Scheidt & Norris-Baker, 1999).

What would an occupational place therapy look like? More than a rigid set of prescribed procedures, such a therapy would focus primarily on attitude and the practitioner's manner of relating to each client. It would focus on identifying customary patterns in the use of space, the role of habit and routine in these behaviors, and ways in which interventions can minimize disruption of habits and routines or create new ones that are consonant with a client's personal history. It would focus on identifying the manner in which each client cognitively orients daily behaviors in relation to the places of his or her life and normatively uses such constructions in accommodating to personal or environmental change. It would focus on developing client-sensitive appreciation of the disruptions of being in place at home that occurs as, with the increasing prevalence of home care, residences become physically and socially transformed into places of care provided by intruders from outside (Dyck, Kontos, Angus, & McKeever, 2005).

Such information would enable the practitioner to provide appropriate support and reorientation in response to changed circumstances. It would explicitly focus on the implications of disrupting long-standing emotional attachments to specific environments and to the artifacts that these environments contain and would seek ways of compensating for such disruptions, such as facilitating the transfer of key personal possessions when relocation is necessary (Wapner, Demick, & Redondo, 1990). And it would focus on framing interventions within the constraints and opportunities provided by the myriad environments that clients vicariously inhabit in their mind—environments that have been displaced in space and or time—that often are key elements in their definition of self. In this domain, key occupational therapy intervention might include reminiscence therapy or other types of activity that serve to maintain clients' connection with the places of their life that constitute their experiential world (Burnside & Haight, 1994; Chaudhury, 1999).

The question becomes how to translate such lofty aspirations into practical terms in the context of home and relocation. Possibilities for facilitating adjustment to either reduced physical capability in situ or a needed relocation include preparation strategies ranging from anticipatory modeling of change (Hunt & Pastalan, 1987) through processes of "constructing familiarity" (Reed & Payton, 1996) to psychotherapy based on "ecoanalysis of the home" (Peled & Schwartz, 1999). Such strategies are designed to prepare clients to deal with the consequences of separation from familiar place and routine and to facilitate the re-creation of place in a manner consistent with changed circumstances.

It is important to add words of caution at this point. First, for some people, expressions of self and of being in the world derive from dimensions of life other than place and home. It can be argued that such "placeless" people might be alienated from their environment and perhaps, by extension, from self. Nonetheless, it is important to avoid the dangers of romanticism and to avoid a stereotypical view of the role of place in people's lives. Second, occupational place therapy might be more appropriate for some clients than for others. For example, people with lengthy histories and multiple experiences of accommodating to change both within their indigenous environment and through experience in place-making gained from frequent relocations might be very adept at accommodating to lifestyle and behavioral changes necessitated by a needed occupational therapy intervention. But what about those who have been more residentially stable and are accustomed to lifelong routines of using a single space and relating to only a few places? Such individuals might experience great difficulty in abandoning familiar routines, adjusting the nature of their being in place in a familiar residence or, should relocation be necessary, transforming a new space into a place. For these individuals, change might be particularly traumatic.

CONCLUSION

There is a tendency in contemporary society to assume that successful rehabilitation is achieved merely by returning individuals to former levels of physical functioning and behavioral competence. Such a view is myopic and demeaning with respect to the richness of human experience. When a practitioner advocates removal of a potentially hazardous throw rug from a client's hallway, offers assistance in rearranging the client's space to accommodate a disability, or provides training in the use of the latest occupational therapy gadget, the practitioner might be enhancing the safety of the home and the physical competence of the client while also diminishing the client's sense of control and autonomy. These interventions might mean discarding a rug that was inherited from a favorite grandmother and transported from home to home over a lifetime—an artifact that is an enduring symbol of family history and continuity. Rearranging the space might move important family photographs beyond the visual field of a favorite chair that, itself, was formerly by the window but has been moved to a safer location that no longer affords a view of activities in the surveillance zone outside. The gadget that the therapist finds so innovative and helpful might achieve its overt purpose but reinforce a sense of inadequacy and incompetence in an individual who might be even better served by accommodating to his or her disability through a less overtly intrusive strategy.

With the hindsight of history, the past few decades might come to be known as an era in which our technology exceeded our humanity as humankind lapsed into hedonistic obsession with material and technological ingenuity. By reinvesting in meaning through place, occupational therapy might be able to help us rediscover our humanity. By seeking new ways to enable individuals to maintain an enduring sense of being in place as a component of the self, the practice of occupational therapy can become elevated to a higher plane.

PROVOCATIVE QUESTIONS

1. How does your relationship to place differ from that of your parents? Your grandparents? Your children?
2. In what ways are the dimensions of being in place outlined in Box 8.1 modified under circumstances in which multiple individuals inhabit a shared residence?
3. In an increasingly mobile society, how will the greater frequency of relocation during the life course affect individual's ability to establish and maintain a sense of being in place? Will the outcome be alienation from place? What are the implications of this for occupational therapy?
4. How can occupational therapy intervention ease the process of relocation?

Learning Objectives

After reading this chapter, you will be able to:

1. Develop an understanding of the meaning of spirituality as related to occupational therapy practice, including definition, related themes, and distinction from religion.
2. Recognize the relationship between spirituality, occupation, health, and well-being.
3. Identify the relationship of spirituality to occupational therapy's history.
4. Understand the relevance of individual experiences of spirituality. through occupation by examining important factors such as context, reflection and intention, and occupational engagement.
5. Describe strategies to integrate spirituality into occupational therapy practice.
6. Explore how spirituality and occupation might intersect in your own life experiences.

INTRODUCTION

As occupational therapy continues to evolve as a profession rooted in the rich and complex notion of occupation, spirituality emerges as an interconnected relevant theme that deserves further exploration. No strangers to confronting

complexity, occupational therapists and occupational scientists grasp the necessity of creating a deeper theoretical and practical base for understanding spirituality as it relates to occupational engagement, intervention, and professional practice. This chapter serves as an introductory resource for understanding spirituality in occupational therapy practice. I begin by asking the fundamental question: What is spirituality and how does it relate to occupational therapy? Second, I will discuss the multiple ways in which spirituality is experienced through occupation. Third, I will integrate spirituality into occupational therapy practice. Last, I will pose reflective questions that will allow readers to explore their own views of spirituality.

FRAMING SPIRITUALITY FROM AN OCCUPATIONAL THERAPY PERSPECTIVE

The multidimensional and complex nature of spirituality defies simple definition. According to Hasselkus (2002):

> Spirituality cannot be directly observed in the physical sense. We are not even at all sure what behaviors we might identify that represent this phenomenon. We have trouble finding the words to describe what we think we mean when we use the word *spirituality*. Yet we probably all acknowledge the existence of some sort of spiritual nature in ourselves and in the lives of all human beings. (p. 102)

Definitions typically emphasize spirituality as a metaphysical and individually experienced internal phenomenon involving an essential spirit, soul, or essence of a person (Egan & DeLaat, 1994; Hasselkus, 2002; Moore, 1992). Individuals might experience spirituality as a sense of connectedness that relates them to a transcendent being, a belief, themselves, others, or the physical world. Recurring themes related to spirituality within occupational therapy and other health professions' literature are hope, faith, coping, and self-transcendence (Haase, Britt, Coward, Leidy, & Penn, 1992; Kelly, 2004; Spencer, Davidson, & White, 1997).

Spirituality can be defined as a deep experience of meaning (Urbanowski & Vargo, 1994) brought about by engaging in occupations that involve the enacting of personal ideologies, reflection, and intention within a supportive contextual environment. Occupational therapy places meaning as a central tenet of the profession, and meaning-making, in its essence, is a spiritual process that seeks expression through occupation (Peloquin, 1997). People often experience spirituality through engagement in everyday activities (Moore, 1992); consequently, occupation creates meaning and helps to answer larger existential questions of the meaning of life (Christiansen, 1997; Frankl,

1959). Recently, the American Occupational Therapy Association (AOTA) included spirituality in the practice framework as a context for occupation, which is "the fundamental orientation of a person's life, that which inspires and motivates that individual" (AOTA, 2002, p. 633). The notion of a "fundamental orientation" evokes an understanding of spirituality as the deepest and most central kind of meaning a person experiences.

Religion is often linked with spirituality and can inform a person's understanding and experience of meaning. Religion is defined as an integrated system of beliefs with their attendant practices (Engquist, Short-DeGraff, Gliner, & Oltjenbruns, 1997). As a set of individual and communal practices, religion permeates many people's experiences of spirituality on a daily basis through occupations such as prayer, meditation, reading theological books, and attending religious services. Not only do religions provide followers with practices that directly relate to theological beliefs, but religious beliefs often ascribe spiritual meaning to daily occupations such as food preparation, work, and intimacy, especially if they are "understood as commanded by God" (Frank et al., 1997, p. 201). Although many people use religion as a tool for framing spirituality in their lives, individual spiritual experience is not dependent on religious affiliation or practice.

Spiritual and religious practices are linked to well-being and health (Low, 1997; Miller & Thoresen, 2003). Spiritual health takes on many definitions but generally connotes being able to experience meaning, fulfillment, and connection with self, others, and a higher power or larger reality (Hawks, Hull, Thalman, & Richins, 1995). These viewpoints also recognize that illness and disease affect the whole person, including the body, mind, and spirit, and all need to be addressed to restore health (do Rozario, 1997). Experiences of occupational alienation (Townsend & Wilcock, 2004), that is, an inability to create meaning and express one's spirit through occupation, demonstrates a lack of spiritual health or well-being for a person (Simo Algado et al., 2002).

It is important to address the right of marginalized populations such as people with disabilities, mental illness, and the aged to experience spirituality and practice religion (Eisland & Saliers, 1998; Koenig, George, & Peterson, 1998; Richards, 1990). These issues of access to occupations as a fundamental human right connect the principles of occupational justice and spirituality (Wilcock, 2001).

Exploring the historical roots of occupational therapy reveals traces of spirituality from the profession's founding. Moral treatment influenced the founders of occupational therapy in the early twentieth century (Bockhoven, 1971). Advocates of moral treatment valued ideals such as holism, humanism, and a recognition that engagement of the mind, body, and spirit through occupation promoted health and brought meaning to life (Meyer, 1922/1977). In the 1920s and 1930s, the medical establishment criti-

cized occupational therapy for its lack of theory grounded in scientific principles (Gritzer & Arluke, 1989). In an attempt to legitimize the profession, occupational therapists adopted reductionistic models through the 1950s, thereby minimizing the emphasis on recognition of the human spirit as expressed in occupation (Yerxa, 1992). In 1962, Reilly expressed concern that the reductionistic view of occupational therapy could not capture the role that occupation could play in facilitating health. Reilly's words proved to be a catalyst for the reemergence of a holistic perspective valuing spirituality as a central concept of occupational therapy (Atler, Fisher, Moret, & White, 2000).

In the late twentieth century, the Canadian Association of Occupational Therapy (CAOT) explicitly integrated spirituality into theories about client-centered practice and occupational performance, placing spirituality at the center of theoretical constructs of occupation that guide occupational therapy practice (CAOT, 1991, 1997). In the United States, the AOTA in 1997 devoted an entire issue of the *American Journal of Occupational Therapy* to the topic of spirituality. Spirituality gained inclusion in the Occupational Therapy Practice Framework (AOTA, 2002) as a context for occupation ushering in the official recognition of the importance of spirituality to occupational therapy in the United States.

EXPERIENCING SPIRITUALITY THROUGH OCCUPATION

A person's ability to create and experience a deep sense of meaning through engagement in occupation makes spirituality compelling. Although spirituality can be experienced outside of occupation, engaging in occupation is the most common and effective mechanism for these experiences because it is through occupational engagement that spirituality becomes more tangible. Peloquin (1997) refers to occupation as an act of making that represents an extension and animation of the human spirit:

> To see such radical making in the acts that we commonly name *doing* purposeful activities, *performing* life roles and tasks, *adapting* to the environment, *adjusting* to disability, and *achieving* skills or mastery, is to discern the spiritual depth of occupation. (p. 167)

Linking occupation and spirituality together with the notion of "making" implies a fluid and active approach to the phenomenon. In making, a person expresses tangibly the intangible yet vital realities of life. This expression, though invariably interconnected with the social world, is ultimately created and interpreted internally by each individual. These internal representations about the meaning of reality and the world drive people to orchestrate occupations to express those meanings (Kroeker, 1997).

Trends within Western society signify a moving away from practices directed by organized religion and toward personal construction of practices for the foundation of spiritual life (Wuthnow, 1998). McColl (2002) contends that given the erosion of meaning in work from industrialization and the prevalence of secular pluralism in modern society, occupation "may be the most effective medium available through which individuals can affirm their connection with the self, with others, with the cosmos, and with the divine" (p. 352). Orchestration of and engagement in everyday occupation holds the potential of helping people to meet the fundamental need for spiritual expression. For example, the busy executive's attending a yoga class, receiving a massage, or taking a hike might serve the vitally important role of facilitating his or her experiences of spirituality.

Contextual Factors

Spiritual experiences through occupation are dependent on and vulnerable to several contextual factors, including the physical and social world. Symbolism is a potent nexus of meaning-making embedded within these contextual factors (Fine, 1999). Places, objects, and communities hold symbolic meanings to individuals that are informed by past history, both individual and communal (Holland, Lachicotte, Skinner, & Cain, 1998).

The physical world can serve to potentially facilitate or block spiritual experiences (Jackson, 1996). Many people communicate experiences of spirituality through occupations in nature such as hiking in the mountains, fly-fishing in a stream, or walking along the beach. Built spaces such as churches, houses, and other structures serve to refine and make more vivid human feeling, perception, and comprehension of reality (Tuan, 1977). Out of experiencing those spaces and the objects within them, a person draws a sense of place that is "an organized world of meaning" (Tuan, 1977, p. 179). For example, a home filled with memories of family gatherings and decorated with special pieces of art and pictures of loved ones can provide support for experiencing spirituality through the occupations that are engaged in within the space. Gathering around a table appointed with grandmother's linens and pottery made by friends, then lighting candles when friends come to share a meal, marks the event as one with special meaning and spiritual import. Whereas home can support one person's experiences of spirituality, for another person, the home might be a place of strained memories and relationships. For a woman who is physically abused by her husband in the privacy of their home, experiences of occupation within her home may show little potential for spiritual experience.

The social world can significantly influence spiritual experience because meaning is both personally and socially constructed (Hasselkus, 2002). Therefore, attempts to

understand spiritual experience involve looking at the doer of the occupation in reference to the social and cultural worlds of engagement. Engaging in occupations with others, or co-occupation (Zemke & Clark, 1996), can potentiate the likelihood of a spiritual experience. Religions recognize the importance of believers practicing their faith with others as a means of mutual support and affirmation of belief (Howard & Howard, 1997). Communal occupations such as attending sporting events, concerts, or political protests as well as family celebrations such as weddings or graduations can be rich environments for spiritual experience.

The Centrality of Reflection and Intention

Spiritual experience also relies on personal reflection and intention. Reflection refers to the exploration of one's inner world and necessarily involves recognition of feelings, emotions, and motivations to act. Reflection also becomes a tool of interpretation that can lead to a setting apart of spiritual experiences as different from everyday life, something special or transcendent (Bell, 1997). Intention involves a conscious imbuing of meaning or directing occupational experience toward something such as a value, belief, or ideology. Reflection or intention in an occupational experience does not necessarily need to be labeled "spiritual"; rather, it may be sensed as deeply satisfying or meaningful.

Occupations engaging a person's creativity offer the opportunity for deep levels of reflection, intention, and ultimately spiritual experience. Kidd (1996), speaking of creativity and spirituality, says, "my creative life is my greatest prayer" (p. 123). Cameron (1992) shares a similar view of the intertwining of spirituality and creativity,

> Creativity is an experience—to my eye, a spiritual experience. It does not matter which way you think of it: creativity leading to spirituality or spirituality leading to creativity. In fact, I do not make a distinction between the two. (p. 2)

Infusing occupation with creativity allows for expression of internal states innately spiritual in nature (Simo Algado et al., 2002). Whereas artistic occupations such as painting, making pottery, or writing poetry show high potential for spiritual experience, numerous other everyday occupations can be filled with creativity as well (Hasselkus, 2002). Occupations such as cooking, conversing with others, or planning a party, along with countless others, can be occupations in which creativity is expressed.

Occupational Engagement

Not all occupations are experienced as spiritual, but all occupations hold the potential to be spiritual. Although people often name occupations stemming from religious traditions as spiritual, the lived experience of such occupations might not be spiritual. Everyday occupations such as work, walking the dog, or gardening might be experienced as spiritual but likely would not be named as religious (Howard & Howard, 1997; Unruh, 1997). Occupations that are deeply meaningful to the person, imbued with personal reflection and intention, and carried out within a supportive contextual environment offer the highest potential for spiritual experience. Kidd (1996) describes the fleeting nature of spirituality in the midst of the details of a normal morning:

> I rose to make the coffee. I walked to the door and paused. When I looked back, I saw my life shining within every ordinary thing. And I was seized by the same feeling I get whenever I see the ocean—the feeling that it is all too much to behold, too beautiful, too much to bear—and I was filled with an aching love for it. In the next instant the moment was gone, and I was climbing down the stairs, walking into the kitchen, into a day of small, humble, distracting things, and somehow nothing seemed more holy to me than just being there, naturally myself, in the midst of it. Such moments are not as common for me as I might wish. But when they come, they leave me with a willingness to relate to my ordinary space—my work and family and friends and all the mundane duties—more authentically. (p. 222)

The demands of routine activities that must be done often blocks the ability to reflect, be intentional, and find deep meaning in the moment (Norris, 1998).

People frequently experience rituals as spiritual, and throughout history, many ordinary activities such as serving food have been used in ritual (Bell, 1997). Common to understandings of ritual are the notions of repetition, fixedness, and predictability that are usually embedded in the doing of religion (Hasselkus, 2002). Outside of religion, any occupation can take on ritualistic characteristics of formalism, tradition, invariance, sacral symbolization, and performance. It is these characteristics that differentiate sacred experience from the more mundane aspects of life (Bell, 1997). Depending on an individual's engagement, an occupation such as taking a bath could be experienced as spiritual owing to ritualized characteristics. Bell recognizes the importance of rituallike performances because they "communicate on multiple sensory levels, usually involving highly visual imagery, dramatic sounds, and sometimes even tactile, olfactory, and gustatory stimulation" (p. 160). For example, engagement in the occupations of a holiday celebration with its attendant ritual practices involving food and particular actions offers the possibility of spiritual experience in bringing together personal, familial, social, religious, and cultural aspects of life (Luboshitzky & Gaber, 2001).

INTEGRATING SPIRITUALITY INTO OCCUPATIONAL THERAPY PRACTICE

As a profession rooted in holistic and humanistic values, occupational therapy holds a unique opportunity to help clients restore meaning to their lives, a vitally important and essentially spiritual task. Although most occupational therapists recognize spirituality as an important aspect of life, integrating a spiritual perspective into occupational therapy practice proves problematic because of its ambiguity and the large diversity of therapists' understanding of the notion (Enquist et al., 1997). Also, in light of the drive toward evidence-based practice, inclusion of spirituality in the core of occupational performance has become increasingly controversial (Unruh, Versnel, & Kerr, 2002). These challenges lead to role ambiguity and a lack of confidence in addressing spirituality in practice in spite of a recognized need for its inclusion (Belcham, 2004). As Howard and Howard (1997) indicate, "occupational therapists need not look beyond the tools, theories, and values of the profession to provide a context for acknowledging the spiritual in the clinic" (p. 185). If spirituality is a deep experience of meaning effectively experienced through occupational engagement, then occupational therapy intervention strategies that uphold holism through occupation-based and client-centered techniques will likely promote clients' spiritual health and well-being.

Recognizing the difficulty of integrating spirituality into practice, Egan and Swedersky (2003) identified four strategies used by occupational therapists who successfully achieve this integration:

- Addressing clients' religious concerns
- Assisting clients' in dealing with suffering
- Helping clients to recognize their own worth and efficacy
- Recognizing their own transformations brought about by working with clients

Integrating spirituality into practice starts with the occupational therapy practitioner (Townsend et al., 1999). Practitioners must consider their own understanding of spirituality and how their spirituality plays out in their occupations and experiences. Additionally, this self-reflective process may lead to the recognition of personal biases or beliefs that could interfere with the crucially needed openness to clients' diverse beliefs and experiences. Self-reflection also aids in the ethically important need for therapeutic interventions to be consistent with the client's spiritual life, not the therapist's (Rosenfeld, 2001). Those who practice therapeutic use of self through active listening, empathy, tolerance, unconditional acceptance, and flexibility toward the client's desires and needs demonstrate a spiritual approach to therapeutic interaction.

Many consumers of occupational therapy have experienced disruptions to and loss of the occupations through which they experience spirituality and meaning. By honoring the subjective experiences of clients in the evaluation, goal-setting, and intervention-planning processes, the practitioner moves toward integrating spirituality into practice and will likely increase the client's motivation (Townsend et al., 1999). Tools such as the Canadian Occupational Performance Measure allow for a client-centered and occupation-based approach that can address spiritual needs through actively integrating the client into the phases of evaluation and intervention (Law, et al., 1994).

A client-centered occupational therapy approach that draws spirituality into practice requires close attention to the client's culture (Simo Algado et al., 2002) as well as the form, function, and meaning of the occupations used in intervention (Larson, Wood, & Clark, 2003). Practitioners sometimes feel uncomfortable integrating clients' religious occupations into intervention. If these occupations are important aspects of a client's daily life, religious occupations such as prayer or reading sacred texts can be integrated into intervention sessions as deeply meaningful occupations. Addressing culture might call for learning more about rituals and religious traditions different from the practitioner's own religious experience or exposure. Clergy from the client's religion as well as family members can serve as resources for the practitioner to increase cultural and religious competence (Rosenfeld, 2001). For clients who are dealing with emotional trauma, occupations that encourage reflection and expression of internal states, such as artistic pursuits and storytelling, can provide opportunity for spiritual insight and coping (Simo Algado et al., 2002).

CONCLUSION

The rich concept of spirituality provides occupational therapists with a valuable tool for understanding the deep meaning of engaging in occupation. Important to clients' health and well-being, integrating spirituality into occupational therapy practice proves relevant to the profession's goal of providing holistic occupation-based and client-centered care.

PROVOCATIVE QUESTIONS

1. How do you personally define spirituality? What life experiences or occupations would you call spiritual?
2. Think of your favorite occupation. How do you feel when you are doing it? How would you feel if you could no longer do it?
3. Think about your favorite places. How do you feel when you are there? What makes them special to you?
4. Bring one of your most special objects to class to share. Why is it special to you? How do you feel when you look at it?
5. What occupations do you engage in that address your spiritual needs?

6. What values led you to choose occupational therapy as your profession?
7. Tell your life story from a spiritual perspective.

II

Narrative Perspectives on Occupation and Disability

"A story presumes both a teller and a community of listeners, such that the act of telling the story and responding to it is a reciprocal exercise designed in part to strengthen community bonds."

Howard Brody

Narrative as a Key to Understanding

ELIZABETH BLESEDELL CREPEAU
AND ELLEN S. COHN

Learning Objectives

After reading this chapter, you will be able to:

1. Explain why listening to clients' stories is an essential component of occupational therapy practice.
2. Explain the relationship between experience, narrative, and the interpretive process.
3. Discuss narrative types.
4. Describe the role of narratives in occupational therapy practice.

Think back over the past few days. How many times have you told a story about an experience you had? How many times have you listened to a story told to you by a friend or family member? We tell stories all the time about the things that we did or that happened to us and to others as a way to share and interpret our experience. In fact, we could be called *Homo narratus* rather than *Homo sapiens* because of the centrality of storytelling to human experience (Fisher, 1984). Some people are better storytellers than others. Good storytellers can infuse their narratives with tension, drama, and suspense, but regardless of how well the story is told, it is human nature to share stories with others. Consequently, it is not surprising that occupational therapy clients and their family members have stories to tell about their experiences with injury, disease, or disability. This unit is devoted to these stories, written by the people themselves, their family members, or occupational therapists who incorporate a narrative perspective into their work with clients. That we devote an entire unit to these narratives indicates the importance of the narrative perspectives of the people who seek occupational therapy and how essential narrative is to the entire occupational therapy process.

In the 1980s, social scientists were rediscovering the significance of narrative as a way to understand human experience, and there was a tremendous growth of interest in patients' stories in the health care fields (J. A. Clark & Mishler, 1992; Kleinman, 1980; Mishler, 1984; Polkinghorne, 1988). The interest in patients' stories of their experiences living with illness

emerged from a "dehumanized" and highly technological approach to health care that lacked sufficient attention to the human aspects of experience. This "narrative turn" in occupational therapy occurred in the mid-1980s when an anthropologist, Cheryl Mattingly, directed the AOTA/AOTF Clinical Reasoning Study, an ethnographic study of occupational therapists in a large teaching hospital (Mattingly, 1994, Mattingly & Fleming, 1994). Mattingly and the research team used observation, interviews with therapists and clients, and videotaped occupational therapy sessions to analyze and uncover the stories that emerged during occupational therapy intervention. In her observations of therapists throughout their work day, Mattingly noted that therapists utilized different forms of talk to discuss their work with clients. Therapists used what Mattingly referred to as "chart talk," a formal reporting register that typically occurred during team meetings and other structured situations to describe the technical and reimbursable aspects of practice. In contrast, therapists told stories during lunch and other times to describe the rich, more interpretive aspects of their meaningful interactions with clients. These stories had all the elements that we have come to expect from a story: a plot, drama, suspense, action, and a moral or lesson. Mattingly's work legitimized the telling of stories as an interpretive process that helped therapists to make sense of their experience. Mattingly's influential work focused attention on the value of therapists listening to clients' stories and explicated how clients and occupational therapy practitioners collaboratively create new or different "meaningful" life narratives in the context of living with disease or disability. She introduced the idea that occupational therapy intervention itself involved a "narrative" process in which the therapy was a dramatic plot to transform the moment toward a path of recovery, healing, or new potential while living with a health condition.

Since then, a significant amount of research in occupational therapy has examined narrative from the perspective of clients (Braveman & Helfrich, 2001; Jonsson, Kielhofner, & Borell, 1997; Knutas & Borell, 1995; Price-Lackey & Cashman, 1996), their families (Cohn, 2001; Kautzmann, 1993), and therapists (Labovitz, 2003; Mattingly, 1991). The narrative turn has even influenced research on meetings (Boje, 1991; Schwartzman, 1998) and team meetings in health care (Atkinson, 1995, 1997; Griffiths & Hughes, 1994; Opie, 1997) and how storytelling influences the clinical reasoning of team members (Crepeau, 1994, 2000).

NARRATIVE AND STORY

There are numerous ways to define *narrative* and *story*. In some traditions, particularly literary theory, *narrative* and *story* refer to distinct phenomena. However, in this chapter, we will use *narrative* and *story* equivalently (as do Hamilton, 2008, Mattingly & Garro, 2000; and Polk-

inghorne, 1988). In everyday speech, stories are quite common, perhaps so "natural" that they do not need explaining. Although common, stories are incredibly complex and quite difficult to describe. In a very fundamental way, stories concern action and offer a way to make sense of experiences. By linking narrative, act, and consequence, stories offer us windows on social life and human character. Some literary theorists claim that through a chaining of events, stories offer causal explanations of events. In this chapter, we will draw on Mattingly's definition: "stories are about someone trying to do something, and what happens to her and others as a result" (Mattingly, 1998, p. 7). Consider an excerpt from Alex McIntosh's chapter (see Chapter 12). Alex's story has numerous features that make stories especially appealing for understanding his experiences in living with cerebral palsy. Alex's story is event centered, concerns human action and interaction, and includes the social aspects of human behavior. As the narrator of this story, Alex knows the ending and carefully selects the relevant details to direct our attention to his plot. He narrates the story in a particular way to convey his message and ultimately communicates to the reader that he has an amazing imagination and that walking with crutches is secondary to who he is as a person. His story even has a deeper moral message: Alex's story teaches us that peoples' ideas about disability are not rationally determined but socially constructed. Alex shows us that a disability is determined by social expectations rather than by diagnostic conditions.

In this story, Alex tells what happened to him and how he and his mother shared an unspoken secret about a naïve woman's social construction and understanding of who Alex really is.

> When I was about seven years old, I was firmly convinced that I was a werewolf. I had never actually undergone any physical transformation at the full of the moon, but seven-year-olds are not bothered by such trifles. The crowning touch was that my crutches acted as a second pair of legs, and although when wearing them I could never really manage a wolf-like lope, I made do instead with a sort of galloping skip. Nevertheless, it was fast enough (to me) to reinforce fantasies of running swiftly through the forest on silent paws, seeking unsuspecting prey.
>
> The technical term for the condition of being a werewolf is *lycanthropy,* after the mythical Greek king Lycaon, whom the god Zeus transformed into a wolf as punishment for his tyranny. I knew the word at the age of seven, having read every book on werewolves that I could both find and understand. I was proud to declare myself a lycanthrope to everyone I met.
>
> One day that year, my mother, my younger brother, and I attended a fund-raising boat race, the object of which was to allow wealthy yacht owners to raise money for the disabled. I was skipping around

the lobby of the yacht club where the event was being held, giving long, mournful, ear-splitting howls, as a proper werewolf should. Mom was over in a corner with my brother, trying to pretend that I was someone else's child.

One of the yacht owners saw me, and she said, "Look at you, doing so well. What's your disability, honey?"

"I have lycanthropy!" I said, beaming.

A few minutes later, she was chatting with my mother and said, "I just met your son. What a nice boy. It's so sad that he has lycanthropy."

Mom smirked. "Um, I think there's something you should know . . ."

That is what happens to people who are lacking in disability awareness.

Alex, now a twenty-year-old, starts his story by orienting us to the characters and setting, placing himself at a younger age. This particular story serves a referential function. In telling about the things that happened to them and others, people connect their experience to the world beyond themselves and provide a retrospective glance at past events. Alex, a seven-year-old boy, who, using his words "could never really manage" a particular gait, transforms himself into a wolf, "running swiftly through the forest, sneaking up on unsuspecting prey" (the yacht owner) to describe to the reader who he is and what he does in this world. Alex has imaginatively transformed himself from a young boy walking with crutches to a werewolf "skipping" and "howling" around the lobby. He communicates his experience, one in which he is not a child with a disability but a competent and clever young boy playing a trick and perhaps educating an adult who does not understand "disability." Alex draws us into his werewolf fantasy as a means to communicate his experience. Yet the narrative moment in this story is not even in the story and has no words. We can only imagine the ironic pleasure that Alex and his mother shared in their unspoken words, "If she only knew." Alex's ending creates an experience for us, the audience, and allow us to infer something about what it feels like to be in his world. Alex's story is worth telling because it conveys to the reader a particular outcome that he feels is important for us to understand. We can share in the joy, imagining what it might be like to have some fun while teaching others that Alex is a clever and imaginative child who happens to use crutches.

We have learned a lot about Alex in his story. We know that he has a vivid imagination, that he has loved to read since he was quite young, and that he is an effective storyteller who can incorporate drama, comedy, and irony into his storytelling. By listening to our clients' stories, we can understand their interpretation of their experience and begin to discern who they are as individuals, their illness or disability experience, and how this experience has shaped their daily occupations. The interpretive process of storytelling helps to differentiate our clients from each other, even those with very similar medical and social histories. While we may work with many clients with the same diagnosis, their lived experience and the stories they tell about their lives will be as important as their particular occupational problems in shaping the way in which we work with them to plan and implement their occupational therapy intervention.

NARRATIVE AS AN INTERPRETIVE PROCESS

Creating stories or narratives is an interpretive process that involves selecting aspects of past experience and representing that experience to others in the present (Bruner, 1986, 1990, 1991). Because storytelling is interpretive, the way in which an individual interprets the past may be strongly influenced by present circumstances. This does not mean that storytelling is a fabrication; rather, stories are constructed to present a coherent interpretation of the past in light of the present.

Drawing on Reissman's (1993) delineation of the multiple levels of representation of experience in narrative analysis, we propose that the chapters in this unit have several levels of representation. These levels are (1) the author's attention to the experience in the moment, (2) the telling of this experience in the writing of the chapter, (3) the editorial process, and (4) the interpretation derived from reading the chapter. First of all, just as Alex was selective, others cannot observe everything in the environment; rather, they select what is important or meaningful to them at that moment, which is then available for a future story. Second, we asked our chapter authors to tell their story to make it accessible to you. In doing so, they have ordered and interpreted events to create a coherent account that you, as the reader, can understand. Because they were asked to write about their experience for occupational therapy students, their stories are told from that standpoint. Their chapters might have a different focus if they were writing for a different audience. In this sense, the chapters are "constructed" for a certain purpose, to convey their experience to readers who will someday be working with people who might have had similar experiences with illness or disability. Thus, the chapters are positioned to reflect experience from a particular interpretive lens: "let me tell you my story so that you will understand the experience of your future clients." In fact, some authors end their chapters by addressing you directly as future occupational therapists to be sure that you understand the importance of their message. The third level of the process involves editing the chapter, which may further shape the story. As editors of these chapters, we tried to sustain the perspective of the authors while helping them to bring clarity and order to their writing. This is a delicate process

because in editing, we ran the risk of changing the representation of their experience by our shaping of it. Finally, you will bring your own interpretive process to your reading of these chapters based on your own life experience.

Telling stories is important. We knew this when we decided to have personal narratives in this edition of *Willard and Spackman.* But working with the authors of these chapters brought the importance of narratives home to us as the authors reminded us of the value to the authors themselves of writing their narratives. Laurie McIntosh said that the chapter she wrote with her son and husband (Chapter 12) helped them to realize the distinctiveness of their perspectives—being a child with a disability, the child's mother, or the child's father. Writing the chapter provided an opportunity to reflect on their individual experience of raising Alex from the perspective of his departure for college, an important developmental milestone. Should they revise this chapter for the next edition of *Willard and Spackman,* they might interpret Alex's childhood differently because of the events in the intervening years. You will see some of this reinterpretation in Mary Feldhaus-Weber's chapter (Chapter 11) in the sections in which she writes about her brain injury at various times from the accident to the present. The basic elements of Mary's story remain the same, but the passage of time and experience have shifted Mary's interpretation. In working on the chapter for this edition, she said that she felt that she could reveal some of the "darker" aspects of her experience because she no longer felt that it was essential to project a strong image. Don Murray wrote his chapter a year after the death of his wife (see Chapter 14). Although he was a professional writer who wrote frequently about Minnie Mae in his *Boston Globe* column, this chapter provided him with a broader vehicle for integrating and synthesizing the experience of her illness, his care giving, and her death. He thanked us for this opportunity and said that it helped him to mourn during the year after her death. Gloria Dickerson's chapter (see Chapter 13) illustrates her exquisite ability to make sense of incredibly painful life experiences and actions that she did not understand as a child. She places her experiences within the context of grand narratives of racism and sexism within our culture and ultimately shows the readers how she shapes her future actions by reflecting on her experience to rewrite and live out a new life story. How you react to these powerful and inspirational stories will teach you much about how your interpretive lenses influence your worldview.

Frank (1995, 2002) argues that in listening to patients' stories, health care practitioners bear witness to suffering as well as to personal strengths and triumphs. The chapters in this unit provide you with a way to begin to think about your clients' stories and what these stories tell you about the clients' character and the meaning they ascribe to their experience. On the basis of listening to stories of others and reading personal accounts of illness and disability, Frank identified three types of illness narratives: the restitution, chaos, and quest narratives (see Table 10.1

for definitions of these narrative types). Frank asserts that these narrative types might not be the only types of illness narratives but that they presented themselves in many of the stories he listened to and read. Individuals may use one or more of the types in one story or may shift narrative types depending on the particular standpoint from which they are telling the story. Frank's purpose in delineating various types of narrative is to sensitize others and to assist them in listening to patients' narratives more effectively. Keeping in mind the three narrative types as you listen to client stories can help you to achieve a better sense of their experience.

Clients telling a restitution story are showing how medicine has resolved their problems to return them to health (Frank, 1995). Clients often tell restitution stories retrospectively, but they might also use this story form to project themselves into the future. A plotline might involve a major surgical intervention, such as a joint replacement, followed by rehabilitation and ultimate return to former occupational pursuits. These stories are easy to listen to because they represent the triumph of Western medicine. In contrast, Frank (1995) asserts that chaos narratives are the most difficult to hear because, unlike the restitution narrative, they are not sequenced by a plotline that we are socialized to follow. Rather, the person who tells a chaos narrative is so embedded in the experience that little order or interpretation is possible. Chaos narratives represent a life that is out of control with no solutions in sight. They are characterized by events that are connected by phrases such as "and then . . . and then . . . and then. . . ." This lack of causal ordering or plot renders the telling hard to understand because the person is still enmeshed in the experience. Quest narratives, in contrast, show the personal transformation that can occur when clients confront serious illness and disability and, as a result, make fundamental changes in their lives. Most of the published illness narratives are quest narratives. For example, Phillip Simmons's book *Learning to Fall: Reflections on an Imperfect Life* (2000) provides a vehicle for him to use his diagnosis of amyotrophic lateral sclerosis as a tool, to understand the way in which he lived in the past and how he pursued a meaningful life despite increasing disability, which would eventually lead to death. By providing clients with the opportunity to tell their stories, no matter how chaotic, health care providers can open an opportunity for reflection or interpretation. This may be as important as medical intervention.

THE ROLE OF NARRATIVE IN OCCUPATIONAL THERAPY PRACTICE

Storytelling

Occupational therapy practice provides many opportunities to listen to and elicit stories from clients and to tell

TABLE 10.1 TYPES OF ILLNESS NARRATIVES

Type	Definition	Characteristic	Basic Storyline
Restitution narrative	A restitution narrative is a common illness narrative that delineates the course of illness from early symptoms and diagnosis through treatment and recovery. These stories may be told by patients or their families and friends. Hospitals and other health care institutions may also use restorative narratives to demonstrate the power of medicine to heal.	A typical plot demonstrates the power of medicine to heal. The focus is on the role of medicine to heal, demonstrating the transitory nature of illness. While the individual tells the story, the primary focus is on the restorative power of medicine.	"Yesterday I was healthy, today I'm sick, but tomorrow, I'll be healthy again" (Frank, 1995, p. 77).
Chaos narrative	A chaos narrative, as its title suggests, represents the lack of control and vulnerability an individual who is ill experiences. These narratives display few elements of typical stories, such as a logical sequence or plot. People telling these stories are so embedded in the illness that they have limited ability to order or interpret their experience. Because these stories tend to be painful and lack the typical conventions expected of stories, they are difficult to hear. Consequently, listening carefully rather than interrupting or changing the topic is especially important.	There is no story line or plot. While the story is about the individual, the person is not an active character in the story. Illness predominates, with a corresponding lack of control by the storyteller or health care personnel.	"Just as the chaos narrative is an anti-narrative, so it is a non-self story. Where life can be given narrative order, chaos is already at bay" (Frank, 1995, p. 105).
Quest narrative	Quest narratives, as their title suggests, represent the transformative journey of a person experiencing serious illness or disability. Like restitution narratives, these narratives capture the diagnosis and course of illness; however, the outcome of the story is focused not on a return to health but on the transformation of the storyteller. Quest narratives focus on how illness has fundamentally changed the person's character, values, and outlook on life.	The voice of quest narratives is the person's, and the quest involves the person's transformation. Illness experience is part of the story; however, the focus is on how this illness transformed the person's life in fundamental ways.	"Whatever has happened to me or will happen . . . the purpose remains mine to determine" (Frank, 1995, p. 131).

clients stories as a form of motivation or to help them see themselves in particular kinds of therapeutic plots (Mattingly, 1998). Occupational therapists also tell stories to each other while socializing and during team meetings and other interdisciplinary forms of communication (Crepeau, 1994, 2000). They might tell puzzling stories to each other to make sense of what happened or determine how they should proceed with a particular client. They may also use stories to persuade others of a particular point of view or insight about a client. For example, an occupational therapist used a very persuasive account of a patient in a geropsychiatric unit to reformulate the patient's problem from one of refusal to participate in the milieu to one of an inability to participate. The occupational therapist's interpretation of the client's story proved to be a turning point for the team in planning care for this client (Crepeau, 2000). Consequently, the therapist's interpretation of the patient's behavior reconstructed the team's view and plans for her care.

Storymaking

While this chapter has focused on storytelling as a way to interpret and share experience, stories do not simply look back and interpret past events in light of the present, Mattingly proposed that narratives can shape action and that occupational therapy intervention involves a prospective "therapeutic emplotment" in which clients and therapists create new narratives; that is, new "stories are created in clinical time" (Mattingly, 2000, p. 183). She argued that therapists and clients create a collaborative intervention process to understand and enable clients to move from where or who they are to where or who they want to be (Mattingly, 1991, 1998). Elaborating on Mattingly's argument, Clark introduced the term *occupational storymaking* to describe how occupational therapists engage people in desired occupations to rewrite, revise, or re-create their life story and image new possibilities. As clients engage in desired occupations and experience their potential to participate in desired activities, a new story is enacted in the intervention process (F. Clark & Ennevor, 1996). Clark (1993) described her intervention with Penny Richardson, a colleague who experienced a cerebral aneurysm at the age of 47. Because Clark listened to Penny and understood her life story, Clark and Penny were able to identify Penny's challenges to engagement in desired occupations and rewrite potential solutions to occupational problems. In one example of the process, Clark and Penny identified the walker as a constant reminder of Penny's continued balance problems and symbol of disability. Before the aneurysm, Penny enjoyed outdoor activities, was an avid hiker, and pushed herself to be physically competent. Recycling her familiar story lines and attending to her motives to remove stigmatizing barriers, Penny began what she called "cane hiking" to transition herself from walking with a walker to using a cane. To rewrite the narrative, Clark

and Penny engaged in occupations that allowed Penny to connect her former self to her new self.

Many of the chapters in this unit provide vivid illustrations of occupational "storytelling" and "storymaking." Nick Pollard (Chapter 15) shows how storytelling in a supported setting enabled people with intellectual difficulties to write, publish, and share their stories with others. These stories provide a window on the lived experience of the participants in the *Voices Talk, Hands Write* project. Theresa Lorenzo (Chapter 16) tells of the therapeutic power of storymaking, which enabled poor South African women with disabilities to recognize their strengths and build more autonomous lives through occupational engagement.

CONCLUSION

Our purpose in writing this chapter is to give you a very brief overview of the importance of narrative to occupational therapy practice. Our hope is that you will read the chapters in this unit and will approach working with others with a respect for the importance of narrative to understand how people interpret their experience and how storytelling and storymaking can be used as part of the therapeutic process. As you read the following chapters, consider the questions listed below.

PROVOCATIVE QUESTIONS

1. What is the plot of the chapter and what is the moral of the story?
2. What are major themes represented in the story?
3. What insights have you gained from the stories in these chapters?
4. If you were an occupational therapist for these individuals, how would their narratives shape your work with them?

MARY FELDHAUS-WEBER

Sally Schreiber-Cohn, CHAPTER EDITOR

UNIT EDITOR'S PROLOGUE

Mary Feldhaus-Weber was in her thirties; lived in Boston; and was a successful playwright, filmmaker, and television producer. She had produced documentaries for the Public Broadcasting System (PBS). Her plays had been produced off-off-Broadway. She had just finished making *Joan Robinson: One Woman's Story,* an award-winning documentary film about her friend's three-year struggle with and death from ovarian cancer. In December 1979, three weeks before this film was to be telecast on PBS, Mary was the passenger in a car that was struck by a drunk driver. Mary was taken from the demolished car and was rushed to a hospital emergency room. Although her head had smashed the car window during the accident, she was released from the hospital that very night. Just three days later, Mary began to have seizures. Months later, she was diagnosed as having epilepsy, a seizure disorder, caused by traumatic brain injury. Her brain had been injured when she hit her head during the car accident. She was never hospitalized for this traumatic injury. Her seizures initially were not well controlled with medication. New medication recently has brought them largely under control; however, she has never been able to return to work.

What follows is Mary Feldhaus-Weber's story of her struggle to live with the effects of her brain injury and seizure disorder—in her own words.

These excerpts were taken from her book in progress, *The Book of Sorrows, Book of Dreams.* The first part of the story covers the years 1979 to 1981. Mary dictated this part of her story to friends and occupational therapy students who were working with her. Mary was able to write the final three parts of her story by herself. Noted throughout the chapter are references to color plates of Mary's painting.

1979 TO 1981

The Accident

Now let me tell you about this. My friend Sally was driving me home at 3:00 A.M. after working on the Joan Robinson film, getting it ready for its national air date. A large American car, going at a high rate of speed, hit the small foreign car we were in, on the passenger side.

I was the passenger. The car we were in was hit with such intensity that both cars were demolished, totaled (see Color Plate 1, "Intersection"). My head went through the passenger window sideways. The side of my head above the temple totally shattered the glass, hit with such impact that every piece of glass had been knocked out (see Color Plate 2, "The Shattering"). People in the emergency room were astonished that I had no facial cuts. I told them my hard Scandinavian head was harder than glass—like stone or a diamond.

I can remember the car lights coming at us. I can remember the sense that we could not get out of the way. I can remember shouting to my friend, "watch out," and then the impact of the car. But strangely, when the car hit, I had the sense that it had not really hit me or the car I was in, that there had been a buffer that was made of time and space. Eternal. Would not break. A shield.

I was also sure that the driver of my car, my friend Sally Schreiber-Cohn, had reached out at the moment of impact and shielded me with her own body. I was absolutely sure this happened. When we got to the hospital, I asked her. She said, "Oh no, I kept both hands on the wheel, of course." If the other car had hit a few inches further back, I probably would have been decapitated. But it hit where it hit. Sally was bruised and badly shaken up. All the damage has been inside my brain.

One doctor described it as if someone were to have taken Jell-O, the consistency of the brain, and thrown it at a wall as hard as one could. That's how hard the brain hit one side of the skull and then ricocheted back and hit the other side of the skull, leaving me with right- and left-side brain injuries. Even though only one side of my head hit the window, both sides of my brain are damaged (see Color Plate 3, "Damaged Brain").

Six Months After the Accident

Six months after the accident, when I started to have more and more seizures, it became clear that I could no longer live alone, so I had to ask my mother to come from South Dakota to stay with me. I did this with great reluctance because she was 78 and my father wanted her there, taking care of him. When she got here, the thing I remember her saying was that she hadn't realized it had been so bad. Why hadn't I called her sooner? This was the time before the seizures were under any kind of control at all, which is to say, I was very sick.

I sat in the corner day after day, noticing that it was light or dark, noticing that my mother was busy, or sleeping, or crying, noticing that sometimes the phone rang or that it was the day to see the doctor, noticing that sometimes I had pain in my head. My mother said, "I wonder if a cold wet towel on your head would help?" I think we both remembered that if a horse sprains its leg, you wrap its leg in towels. And so Mother would get wet towels from the bathroom and wrap them around my head, my brain becoming like a sprained leg, a muscle that wasn't working. Cramped and tense. Convulsing. Filled with fear.

And then because things change and time moves on, the pain would stop, and I would become briefly aware that the couch cover was blue, or that the dog had been rolling in the dust, or that Mother wanted to fix soup for lunch. And we discovered that after I had a seizure, or as one doctor called them "spells," I didn't have the coordination, or was too confused, to drink soup or hold a spoon. Because Mother liked soup so much, we seemed to try this many times, larger spoons, smaller spoons, bigger cups, smaller cups. It was decided that tomato soup was the easiest. Why, I'm not sure. Finally, I told Mother I did not like soup and had not for years. Therefore, could we try something else?

At this time, I was having constant seizures. There was no time that I was not either having one, getting ready to have one, feeling "spacey," with a strong metallic taste in my mouth, or feeling confused and disoriented after having had one. I felt like the seizures were a powerful force outside of me that suddenly grabbed my brain, me, the essence of me, and with the kind of fury of winds, blizzards, and driving rain, held me under ice (see Color Plate 4, "Blue Seizure"). While the *me* that was present could breathe the water under the ice, I knew I was caught, forced to be there. I knew if I struggled even slightly, the pain, the terror, became worse. And for the time the active seizure was roaring on inside me, I had to concentrate on total stillness until the fury dissipated and I was released.

All the drive and the tenacity, the ambition, the creativity, all of the things that had made me who I was did not help in this place. I was terrified, and I was alone. I no longer knew the words to ask or tell anyone what I was living through. I could just sense what hurt, and it hurt less to be absolutely still until the force chose to release me. I had no control of when it seized me or when it chose to release me.

My friend Sally tells me now that looking at me was like watching a candle about to go out. It seemed to her that only 3 percent of me was left.

I felt that I was being annihilated. The *me* that I had become, lived with, was ceasing to be, over and over and over again. It occurred to me that this was what it felt like to die and, for whatever reason, I was dying again and again.

One Year After the Accident

My mother had to return to South Dakota, so I was living alone. One day at the neurologist's office a year after the accident, still confused and in a deep fog, I noticed the doctor's tie. It was a bright, clear yellow Marimekko tie. I stared at the color yellow. It was the first thing to make sense to me since the accident. I understood what I was seeing. The color yellow. The fog lifted for a minute. I understood something, and I had not had to struggle to understand it. I can remember thinking: I am going to be all right.

When I got home that day, someone got me a set of poster paints, and I painted a small, bright, vivid, yellow daisy (see Color Plate 5, "Daisy"). And I started painting. When I began painting, I was surprised to find that it didn't turn out so badly, even though I had never painted before. Painting was one thing I could do all by myself, whether anyone was there or not. It didn't matter if I was spacey or sick. I could just lay down the piece of paper I was working on and continue again after the seizure had come and gone.

Some days, I did as many as ten paintings. Looking back, I realize that I was desperate to understand my situation. I could hear people talk, but nothing made sense. I looked at their faces. I watched their mouths move, but I could not concentrate on what they were telling me. I can remember thinking: I have to try to explain all this to myself—what is happening to me—because I can't understand anyone else. So I painted. The only time I felt like the person I used to be was when I was painting.

I started finger painting with acrylic paint, wet tissue paper, and poster paints. I was drawn to the colors and shapes of things. I started to paint brains. I tried to paint the experience of seizures, which I did over and over again (see Color Plate 6, "Hemisphere"). In a strange kind of way, it was like having an artist's model for myself—not a model I could see, but a model which was myself, an internal experience that I then tried to translate into color. The painting gave me something to talk about other than myself. Something to talk about when people came to the house. It was a relief to have something to show someone, to have them look at pieces of paper, not to look at me. It also gave me a way to try to talk about what I was living through. Part of me hoped that the paintings weren't pitiful, because of all the things I did not want to be, to be pitied seemed the very worst.

I was also aware that I had to start from scratch with painting. I had been at the top of my career in film, and now I had to struggle to squeeze the paint tubes. I had to learn to be patient with myself. I was at the very beginning and grateful to be there.

Two Years After the Accident

I still had no real picture of what happened to my brain, to I spent a great deal of time thinking about it. Trying to think about it (see Color Plate 7, "Dendrites"). I had listened to explanations from doctors, nurses, and social workers, and none of them had made sense. All I knew was that I was unable to do the simplest thing—make a bed, tell time, count. Add or subtract. Recognize faces. Tell right from left. Read. Understand what people said to me. Remember things. And perhaps worst of all, I did not feel like myself, like *me.* I felt like someone, but not like any one I knew. I was a stranger to myself. I was lost (see Color Plate 8, "Self-Portrait").

On days that I had constant seizures, I had to ask my friend Sally to come and stay with me. It was at these times that we were aware that I was not getting better; in fact, I was barely hanging on.

The everyday litany was long and grim: I fell all the time; I was covered with black and blue marks everywhere. I would come to from a seizure to find that I had bitten the inside of my mouth and was bleeding and had a shard of my broken front tooth sticking out of my bottom lip. Sometimes, I would put my finger in my eyes during a seizure, and the eye would be red and swollen for days. I hit my head. I broke my elbow. It did not seem safe for me to live alone.

I had lost my income when my film company closed after the accident, and I had lost my health insurance with it. Because of these factors, my only option would have been to go on welfare and go into a nursing home. My neurologist felt that if I did that, I would likely never come out. I think he had seen too many people become institutionalized. In other words, they had become helpless and had given up. I still had some small fight left in me; I had been a functional, successful adult. The 3 percent of me that was left was 3 percent of a fighter. We were all counting on the fact that I would keep fighting and I would get better. That somehow I would manage. I also knew I desperately needed someone to help me help myself.

Finally, more than two years after the accident, we found someone to help me. Sally had called a therapist friend who said that she did know someone who was a gifted occupational therapist and liked dogs. And who was kind. When Sally called the occupational therapist—Anna Deane Scott—she said that she knew very little about head injury. She was a professor at Boston University and the coauthor of a famous occupational therapy textbook, and, yes, she did like dogs. She agreed to come to my house to meet me.

When she first met me, Anna Deane told me later, I was sitting in the dark on a couch, crying. We talked; she admired my dogs and told me about her own dog. After she left, I called her to ask what she thought of the meeting. I was afraid that she might have felt I was beyond help. I asked her how she felt about meeting me. Anna

Deane said, "I felt sad." She told me the truth. I knew I could trust her.

Every time Anna Deane came over, we talked about things in the house that were a problem for me. I was afraid of falling in the shower when I was getting spacey from a seizure, so we got a shower chair and a metal bar on the wall and rubber rugs inside the tub and outside the tub. Each one of these areas we worked on took months to identify the problem and with trial and error find the solutions. But in the case of the shower, finally I was able to take a shower, and I was no longer afraid. I was also afraid of burning myself on the flames of my gas stove if I was feeling confused, so we got a large electric hot plate, and I could heat something up without being afraid of lighting myself or my clothes on fire.

I had lost the ability to do things; I knew there were steps to take to do any task, but I had no idea which step came first. I later learned that I had lost the ability to sequence, a loss that sometimes occurs when you have had an injury to the frontal lobe of the brain.

Anna Deane and I set out to discover how to teach me to do things again. She said that there was always another way to do something. First we had to find out how I was still able to learn. You will notice when I speak of Anna Deane and myself, I always say WE did this, WE decided that. Unlike many other health professionals, Anna Deane felt her role was not to tell me what to do, but to work with me, to empower me. She asked me constantly what was important to me. What did I think of something? What did I want to do? And she LISTENED to me. Extraordinary!

One problem in my life was how to unlock my front door. My house has two doors, an outside door and an inner door, and therefore I have two different keys. If someone would bring me home from the doctor's office, one of the few places that I went, I would often try to get the key in the lock and not be able to. I would try to unlock the door for what felt like hours, over and over again, desperately trying to get into my own house. I asked whoever dropped me off to see that I got into the house before they drove off. Often they would have to open the door for me. I felt stupid, unable to do the simplest thing.

Anna Deane watched me try to get into the house and said she understood what the problem was. She said when I couldn't get in the outside door with one key, that I should try the other key. It had not occurred to me to try the other key. I would stand endlessly with the wrong key doing it over and over again, but when I had this new strategy, it freed me to get into my own house, and each time I opened the door myself, it was such a victory. And I began to feel hope for myself.

Anna Deane and I discovered that it was impossible for me to just follow or understand verbal directions, but if I could also watch someone do a task, listen to the directions, even place my hands on the things at the same time, I could, after a number of tries, do it again myself.

Anna Deane said that we could not be sure which parts of my brain were still working, but we had the best chance for success if we used as many senses as possible, hoping that we could tap into the areas in my brain that still functioned. When Anna Deane first said this, it sounded like the most primitive kind of investigation into unknown territories, all of which were inside me. We were searching for the *me* that was still there. But she was right. With Anna Deane's help, I have learned to do everything (day-to-day self-maintenance activities) over again—absolutely everything. It is not too strong to say that she gave me my life back.

Another thing that Anna Deane and I worked on was a chart that monitored my daily activities. One of the problems was that I had lost any sense of time. With epilepsy, it is important that you take a certain amount of pills at a certain time every day. It's very simple—if you don't, the seizures come back. You also have to eat and rest regularly in relationship to taking the pills, and before I met Anna Deane, I could not remember whether I had taken a pill, had lunch, let the dogs out; I couldn't tell if it was afternoon or morning or what day it was.

Gradually, over a period of months and many failures, we worked out a chart on a magnetic blackboard that we divided into morning, afternoon, and evening. We used different colored magnets for different parts of the day, as we discovered that I could understand colors better than words. For every victory, such as the discovery that I still remembered colors, there were dozens of defeats. Anna Deane said over and over that there was always another way to do something. We just had to find the other way. And every time we failed, she learned that much more about my brain, what still worked and how it was working. She said there was no such thing as a "failure." She learned something each time we tried something new.

I, on the other hand, felt the failures very keenly. Because I had been quick and life had come easily to me, I was not used to trying and failing at something simple again and again and again. The things we were trying to do, such as a system to get me to remember to take my pills, were both very simple and very important. I was impatient with myself and judged myself by who I had been. For each failure, I shed many tears.

I tried not to cry in front of Anna Deane. My dogs, Desmond and Todd, listened to my crying. I would go to pet them, and their fur would be wet. I would be puzzled at first and then remembered I had been crying. And they had been sitting beside me on the couch, wet with my tears.

Anna Deane said that I was doing what I needed to do, grieving over my losses. I had lost a great deal. And that if one didn't grieve and let the past go, it was harder to do new things. That grief could stand in the way of progress (see Color Plate 9, "The Color of My Grief"). But on the other hand, I also needed to look at the balance of things. I needed

to find things that still made me happy, gave me pleasure. It became my job each day to do one thing that gave me pleasure (see Color Plate 10, "Goblin"). This sometimes was as hard to do as the task of grieving. It became obvious to me that the two were connected.

So we refined the magnetic board system further: colored magnets for each time of day, further divided into take pill, have lunch, feed dogs, and so on. When the activity had been completed, I moved the magnet from the not-done category to the done category. The chart is large and colorful, and I can look at it from across the room and tell what I have done and what I haven't done yet and how I'm doing. And so, eventually, time and memory seemed somewhat under my control again (see Color Plate 11, "Healing Brain").

Anna Deane came to my house every week for an hour, and we talked on the phone a number of times between the visits. In the year that I worked with her, I could see small changes in my life; and as I got greater control over the details of my life again, the person who I had been started to reemerge. I wasn't making films, but I could change the sheets on my bed. I wasn't writing poetry, but I could dress myself. These may seem like small things, but with each skill I regained, I could feel life flowing back into me again.

Another triumph that stands out was the ability to get into and out of buildings. There are many buildings in Boston where you have to buzz the company or office that you are going to, and then they buzz you back and the door opens. I was no more able to decipher this than the Rosetta Stone. It was impossibly complex for me and therefore overwhelming, and therefore tear-producing, and therefore one more thing that I couldn't do.

Anna Deane and I talked about every possible kind of solution and came up with one that worked. The solution was to stand and watch until someone else came along and pushed a button and got in the door, watch how they did it, and either go in with them or do the same thing they did. And it worked.

In large buildings, it's still a problem finding the correct office if I haven't been there before, because in the elevator, I am not able to understand whether 5 is the same as 7 is the same as 9 when the elevator opens. So I have been lost in the best hospitals in Boston. The people who had taken me went to park their car and against their better judgment let me out, me telling them not to worry about it, that I would meet them at the office. And then, 45 minutes later when I did not show up at the office, and it became clear that there was a problem, various people would be sent to find me. For my part, I would be asking people if this was the fourth floor, etc., etc.

Among the least helpful people to give this kind of simple direction are doctors, nurses, or anyone else from "the allied health professions." Among the most helpful, of course, are the other patients and all the cleaning and maintenance people. However, Anna Deane and I have not figured a way around this problem, a way to make me independent, to do it all on my own. It is still, sadly, something that makes me cry.

With Anna Deane's help, I listened to talking books for reading and used a calculator to add and subtract, told time with a digital clock, asked people to take me places and not just give me directions, and used the brightly colored arrows that told me which way to turn the thermostat to heat my house and to turn on the water faucets in the shower. In other words, many victories. And more to come.

Sometimes people ask me what kind of fee Anna Deane charged me for this amount of work and of devotion. The answer is—not one cent. She told me that she did not know enough about brain injury to charge for her services; it was a learning experience for her too. And she did not say it, but I knew she knew that I did not have a cent to my name.

MAY 1996: SEVENTEEN YEARS AFTER THE ACCIDENT

How am I now? I was told that if a function did not come back after a year, it would not come back. They were wrong about this in some cases. I have continued to regain things over a period of 16 years. I can discriminate between right and left again, I am much better at recognizing faces—not perfect, but better. I can understand poetry and most abstractions again. I regained my sense of smell. I can read a bit if the print is big. I can write again.

I still can't count. I still can't do multiplication tables or months of the year. I still see double out of one eye. I still have to sit and think a long time about what steps go into a task such as putting the laundry in the washing machine and what order those steps should take. I still have balance problems. I still have a lot of seizures—several a day most of the time. I have learned to live with these things—the things that are lost to me and the things that have come back but are different.

I had a battery of neuropsychological tests done on me recently, and I still do badly on a number of them. You are reading the writing of someone who now has an IQ still considerably under 100.

I was surprised how many strong feelings I had when I started to answer the simple sounding question—"How are you?" First of all, it is not until I started to get better that I realized how much I had lost. Before that, I was too sick or too overwhelmed to notice, to understand the breadth of the loss. In broad strokes, I lost 10 years of my life where I almost ceased to exist. And I still grieve over that loss; some days it feels like a very big loss, other days it doesn't (see Color Plate 12, "Broken Dreams").

So how am I now? I am doing better without having gotten better. In other words, I learned to do a lot of things in new ways just as Anna Deane Scott, the occupational

therapist who worked with me, said I would—tell time with a digital clock, read with talking books, write with a large-screen, large-print computer. I feel like myself again. I am happy most of the time—in fact I seem to be one of the more happy and contented people I know. I have become grateful for things large and small. I am more appreciative of other people. In fact, I think we should all gets stars and bluebirds for getting up in the morning. The head injury has forced me to look at myself. Look at all the sad, angry parts of me that I did not consider when I was a hotshot television producer. I was too busy working 18-hour days. Being very busy in a high-visibility job can be seductive. What you are doing seems so important that you can easily push everything else into a corner. But when you are sitting home, day after day, when the phone isn't ringing off the hook, it is less possible to ignore things.

Being brain injured has given me time to look at who I was, how I got there, and to ask myself what I want to do about my life. Counseling also helped me to survive many assaults on the spirit that can occur when you are forced to endlessly deal with health care providers. Being a patient can be a grueling life. I know that this will seem strange; it seems strange to me even as I write it down. There is a belief that if you have one sense such as sight taken away, your hearing becomes more acute to compensate. To understand my own suffering, I have come to better understand the suffering of others.

I also laugh more, am made happy more easily. I am much more at ease with myself. I feel quite literally that I walked and walked and walked through the valley of the shadow of death, stumbling, crying, falling, breaking bones, and finally came out on the other side. When asked about the brain injury, I tell people I would not wish it on my worst enemy. Yet strangely, I am also grateful for the journey.

JULY 2001: TWENTY-TWO YEARS AFTER THE ACCIDENT

I continue to live with the physical problems that came from the original injury. And there are still the problems I have because I am who I am. I was on the phone recently with a spit-and-polish person that I don't particularly like. At a point in the conversation, I was not able to understand what she was saying. And then I started perseverating—saying the same word over and over again, which she didn't notice. These signals told me that I was probably about to have a seizure.

I felt frustrated and ashamed. I could do nothing to stop the seizure. Worse still, I thought I might start crying, but I forced myself to be polite. I finally hung up when I began losing the ability to speak. And I felt terrible about myself. I could hear Anne Deane Scott's voice when I used to tell her about this kind of social situation: "Just hang up the phone. And if they don't like it, too bad

for them!" A life lesson I have yet to learn. Even after these 22 years, I still need to please others at my own expense.

I have had the best help in the world, so why don't I learn these lessons? I suppose that is because I am a human being and I still carry the same baggage I had before the accident.

And now I think it is time to tell you about good things.

About five years ago. a new antiseizure medicine came on the market that has made a large, positive difference in the quality of my life. At long last, I have fewer seizures and am more clear-headed. I am *me* more of the time. It's wonderful. I have a computer and like it for all the same reasons that everyone else does. Even though I am mostly house-bound, I have the world in front of me.

I have always loved animals, and now I am active with animal rescue and finding homes for abused, homeless animals (see Color Plate 13, "I Stand by While Good Dogs Die"). Since a large part of this can be done on the phone or the Internet, I can do this when I am feeling okay. I have become part of a network of people who care about animals as much as I do. They have no idea that I used to be a filmmaker or even that I was in a terrible accident, although I do tell them about the brain injury if there is a reason to. I never have to fear that anyone will feel sorry for me. I am just one more person who is dedicated to helping animals.

I love this part of my life.

In the 22 years since the accident, I have gone from not being able to read and write at all or to even turn the pages in a book to be able to write what you are reading right now. I write easily now.

Finally, there is something unexpected that I seldom hear discussed by brain-injured survivors or the people who work with them.

The car accident was a crushing, wrenching assault on me. For the first few years after the accident, the question that I asked over and over was this: How could God do this to me?

Before the accident, I had been a spiritual person. I believed in a compassionate, wise God who cared about each sparrow that fell and each lily of the field.

After, it seemed like God cared about everything but me. I was shocked and heart-broken that God let this happen. I thought about it constantly and talked to anyone who would listen. I felt twisted and damaged inside and out (see Color Plate 14, "When I Think of Dying")—and angry. Angry. Angry. You can see this in my paintings (see Color Plate 15, "Pain#2").

The years went by, and I never came to any understanding. After a time, my sorrow blew away like smoke (see Color Plate 16, "White Brain"),

I understand now that the greatest damage I experienced was the damage no one can see. It left me feeling afraid of things, not trusting in life, not being able to believe in a kind, loving God. I felt alone.

I have had the best occupational therapy and counseling and profited from them. I have learned to do many of the skills of daily living again. I have changed and grown.

And there is more.

My spirit has been the last to heal.

I am still healing.

JULY 2007: TWENTY-EIGHT YEARS AFTER THE ACCIDENT

When I first heard the term *occupational therapy,* it made me think of a black-and-white photograph from the turn of the century with dozens of sturdy young women working at looms. It was the word *occupational,* of course. As it turns out, occupational therapy deals with all the things that make us feel human—the delicate interchange between mind and body. I've heard brain-injured people say, "I don't feel like myself." And I've said the same. I had experienced a shocking, terrible interior change that took away my ability to be and do. Occupational therapy helps us to realign ourselves, cell by cell.

When Anna Deane Scott started working with me, she first had me tested. The doctors in 1982 were perplexed because I had been unconscious only for a few seconds. Usually, there is more lack of consciousness to have so much damage. Of the many problems that the tests pinpointed, my ability to *sequence* proved to be the most damaged. In other words, I knew there were steps to do things but had no idea what order they came in. Therefore, I literally couldn't count, couldn't say the months of the year, the days of the week. I couldn't tell time. I couldn't read. Unfortunately, the world is made of sequences.

Another problem was an inability at times to find a name for an object or even recognize it. To work with this, Anna Deane said that we should try all of my senses—touch, sound, and so on. One time she put a number of things—lipstick, comb, pencil, spoon—into a sack. I was not able to recognize them with my eyes. When I used my sense of touch, I was able to recognize them, to understand them, and to give them their names with my fingers. I told Anna Dean I felt like Helen Keller when she signed the word WATER for the first time. It was victory for me. It was hope. It was making the undamaged cells take up another function. And they did, even though it has taken years.

Experts in the field of brain injury in 1982 told me that young adult males were most likely to have head injury. And being young, they were quicker to heal. Women my age, on the other hand, statistically did not often suffer brain injury and, being older, did not heal as quickly. These young people hadn't lived very long and therefore did not have life experience and, because of this, did not have as many life skills as an adult does. I, on the other hand, an older woman—me—had developed a set of work skills. I knew how to do a lot of things. I had been a television producer and filmmaker. To be a successful television producer and filmmaker, you have to have tremendous drive, know how to make things happen, and be a hard worker. The accident had not crushed those parts of me. That and the creative part of me were still there, although at the time, I didn't know this. I was just trying to fill my days, which were also filled with seizures and confusion.

If you look at my paintings, you can see how simply they started. I used finger paint, water, and torn tissue paper. I painted at least 10 paintings a day. Make a painting, lie down, and rest. Make a painting, pet the dogs. Make a painting, cry. Make a painting, stare at the ceiling. And gradually, and with the grace of God, I began healing. There was another plus to my painting. When an artist friend and other friends came over, we often talked about paintings. I had something other than pain and suffering to talk about. Above all, I didn't want people to feel sorry for me.

I have thought so many times that I was lucky to have been born at this time and this place. I was lucky to have lived at a time when people were starting to understand head injury. Head injury—people call it brain injury now. One hundred years ago, if I had this kind of brain injury, I might not have lived through it. Or if I had lived, I would have been tied to a chair in some dreary institution.

On the other side, there were many dark times when I often thought it would have been easier to die. Because life had become an unendurable burden. I didn't feel like myself. I had lost myself. I felt that I would always be caught in this terrible web. It seemed that there was no way out of it. And how could God have done this to me? What did I do to deserve this? I thought of suicide constantly. I didn't talk about this. Not to my parents. Not to Sally. Early on, a man who was educated and sophisticated about the ins and outs of the head injury world visited me. He was kind and reassuring. He also had a brain injury and epilepsy. He told me not to tell anyone you feel suicidal—you would be pink-slipped "for your own good." Meaning you would be put in the insane asylum. Particularly do not tell any of the doctors, he said; and I believed him. You can bet I believed him. That was all I needed, to be in an asylum.

For a time I was in a discussion group of people with seizures and brain injury. I listened to far too much horrifying "for your own good" that had been done to people. But that is another book.

I am speaking in my own voice right now—not the voice of the overwhelmed, defeated person. In fact, at the time, I was still unable to do the simplest things. And Anna Deane Scott, bless her heart, sent out some of her occupational therapy students to my house to work with me for academic credit. They were wonderful. We all gained. They learned firsthand about brain injury and I learned to do things that I was not able to do on my own. I wanted to write a story about my Jack Russell terrier, Todd. The students wrote down the Todd stories that I was not able to read or write myself. I said the words one by one, and the students wrote them down one by one.

The story was named "Todd and the Stars." I was painting and the students went to the store to get yellow paint for me. And they helped me. They were like sunshine coming into a dark room. Anna Deane was so smart. I kept painting. I could see that my pictures were getting better. And though I didn't know it at the time, I was getting better.

I was healing. I lived and went on to tell this story. And I am glad to be alive.

It has been 28 years since the car accident. I had learned to live with my brain injury. For the most part I'm fine at home, with my friends, in familiar places. But I forget that I am not okay in the eyes of the world. I do not do well with new situations. Several years ago, I needed a knee replacement and went to a highly thought-of hospital and rehabilitation facility. After the surgery, I was brought back to my room, groggy, crying, confused, and in pain. The nurse on duty told me that there was a way of controlling my pain—I only had to push a button by my hand and I would receive the right amount of pain meds. She demonstrated it and left. The pain went on and on. My friend Sally could see that I did not understand the sequential steps to make the pain machine work. She called the nurse and told her that I couldn't understand how to use the pain button because I had a brain injury. Sally asked—could she push the pain button for me? The nurse said Sally most certainly could NOT touch the machine and that I had to do it for myself.

A frustrated Sally repeated about my inability to deal with sequences and because of that, I wasn't able to use the pain machine. The nurse told us that everyone is capable of using the pain device—even people 80 years old can do this and "so can you." The nurse left. The pain continued. Sally called for the nurse and again explained about my brain injury. This sequence went on a number of times. I am not sure how it resolved itself, but finally another nurse came in and started to give me shots for the pain. This was the first of many other such episodes. The staff seemed to think that if I was able to talk, I should be able to understand what they wanted me to do.

Next was getting out of bed. There are steps to learn to get out of a bed after knee replacement surgery. A nurse and a nurse's aide told me what to do over and over. I asked over and over and tried to understand what they were telling me. And, worse still, when I struggled to explain something my speech became garbled and confused. The nurse's aide turned to the nurse and asked what was wrong with me. The nurse looked right at me, put her finger making a circle around her ear—the sign that children use to mean "crazy."

This, even though Sally had told all the nursing staff about my brain injury, had put a sign over the bed to that effect, and had made sure the information was added to my medical file along with my own doctor's evaluation of my situation. Most of the nursing and medical staff were not interested in anything we had to say about my brain injury. They completely dismissed what Sally and I said. Further, alas, they were quick to criticize and say that I wasn't trying hard enough. They talked about me in front of me and others. They talked to me like I was a badly behaved child.

Some of the more frightening situations came up when the rehabilitation people were trying to teach me to do things on my own: go up stairs, get in and out of the bathtub, or walk with the walker. I was frightened because they didn't listen to a word I said. I know how dangerous this situation can be for me. At home, I have fallen and broken bones, broken teeth, bitten the inside of my mouth, and put my fingers in my eyes. These people didn't listen to me about my brain injury. I asked to speak to the supervisor and described the situation I was in. I talked to her about the rehabilitation staff not listening to me. The supervisor said that they must have been tired that day. I talked to my doctor about the same thing. He said to write to the president of the hospital and that no one listened to him either.

Finally, thank God, I got out of that place. It had been a nightmare. All too often this must be how some people—the old, the retarded, the insane, the poor, people who don't speak English—are treated. What they have to endure. And so did I.

Time passed, and I needed to go to a hospital for pneumonia. This new hospital was a far different experience. It is known for its innovative work with brain trauma. The staff took detailed information about my brain injury. They were as interested in it as the other place was not. I sighed with relief. I didn't have to struggle to communicate. When I said I had temporal lobe brain damage, they understood. It was like coming to a different country. And I no longer had to be in a defensive posture. Better than that—they believed me when I described the characteristics, albeit very strange even to me, of my brain injury.

And now on television, I see our men and woman soldiers, damaged, crushed, brought back to many armed services hospitals and rehabilitation facilities where there might be very little or no concept of brain injury or how to deal with it. I would guess that these people coming back from the war and their families are going to run into problems similar to the ones I had and that my friend Sally encountered on my behalf. A recent article in *DISCOVER* Magazine entitled "Dead Men Walking: What Sort of Future Do Brain-Injured Iraq Veterans Face?" by Michael Mason (2007) describes the situation faced by these veterans. When I read this article, it broke my heart because I know brain injury can be a lifelong tragedy.

> In a flash, the blast incinerates air, sprays metal, burns flesh. Milliseconds after an improvised explosive device (IED) detonates, a blink after a mortar shell blows, an overpressurization wave engulfs the human body, and just as quickly, an underpressure wave follows and vanishes. Eardrums burst, bubbles appear in the blood-

stream, the heart slows. A soldier or a civilian can survive the blast without a single penetrating wound and still receive the worst diagnosis: traumatic brain injury, or TBI, the signature injury of the Iraq War.

But in the same instant that the blast unleashes chaos, it also activates the most organized and sophisticated trauma care in history. Within a matter of hours, a soldier can be medevaced to a state-of-the-art field hospital, placed on a flying intensive care unit, and receive continuous critical care a sea away. (During Vietnam, it took an average of 15 days to receive that level of treatment. Today the military can deliver it in 13 hours.) Heroic measures may be yielding unprecedented survival rates, but they also carry a grim consequence: No other war has created so many seriously disabled veterans. Soldiers are surviving some brain injuries with only their brain stems unimpaired. (Mason, 2007, paragraphs 1–2).

Later in the article, Mason goes on to write about the rehabilitation possibilities for brain-injured soldiers. When I read this part, I thought about all the things occupational therapists could bring to their suffering. In an interview, Marilyn Price Spivack asserted that

Men and women in the military will receive excellent care for a time, but eventually, they are going back to their communities. "The military is doing an extraordinary job in saving young soldiers and treating them through the acute rehabilitation phase," says Spivack, who works with the brain-injured population at Spaulding Rehabilitation Hospital in Boston. In the early 1980s she founded the Brain Injury Association, today the foremost advocacy organization for TBI survivors. "Now the government must make a commitment to help them in their recovery, but where are the resources going to come from? As brain-injury professionals, we know that TBI services aren't available in many places across the country, and we are aware of huge holes in the system," she says. "Frankly, I'm frustrated and angry about the government's refusal to give the TBI population the support it desperately needs."

Spivack is not being glib; the giant holes are glaringly apparent. Many states do not have a single brain-injury rehabilitation center, and of the states that do offer some level of TBI treatment, few actually provide enough assistance to acquire even the most basic level of specialized care. At rates that can exceed a thousand dollars a day for postacute TBI rehabilitation, there aren't many American families that can afford a month's worth of treatment, much less the recommended minimum of 90 days.

As recently as mid-July 2006, the VA Office of the Inspector General admitted that patients and families were dealing with major inadequacies. The reality is that a fundamental level of care is simply absent in most states. (Mason, 2007, paragraphs 29–31)

I encourage you to read Mason's powerful article (see on the ON THE WEB, p. 115). I fear that these veterans will come up against the worst kind of ignorance—people who don't know that they don't know. This is an enormous situation that has no easy answers.

HOW AM I NOW?

I often wonder how things would have been if there hadn't been a car accident. As it is, I have lost many years of my life. Some of those years were complete dropouts, because there are not words for what I went through. I felt that I had fallen into a deep, deep pit. I was alive but not alive. Gradually I have gotten better in many ways.

I have four or five hours in a day—good hours when I can do things. If I go past that, my speech becomes garbled, my coordination is bad, and I have to worry if I will fall. I have to be SO careful about hanging onto things so I won't fall. I have handles and grab bars all over the house that help me walk. But if I am too exhausted, I have to stay in bed. If I do a small thing that's just too much, my brain becomes frozen, rigid, or like an old car, or a cranky baby. I never know when it will choose to give out. When this happens, I have to be quiet and let it rest.

There are things I wish I could do. I would like to go horseback riding. I'd love to go to movies. I'd like to go to Sweden and see the midnight sun again. I'd like to go to a symphony orchestra again. I'd like to see the cherry blossoms in Washington. And the redwood trees. And Animals in Africa. And sit through five days of a film festival. And go dancing with a good-looking man—a rascal.

The one movie that I tried to go to, I had to leave and sit in the accessible ladies room because of overload from the pictures and sound. I had to say to the people I was with that I had to go home. It was the *Pirates of the Caribbean,* and I enjoyed the 30 minutes tremendously.

FIGURE 11.1   Mary, Sally, and LaBeam chatting in the garden. (Photo courtesy of L. Nugent, Photographic Services, University of New Hampshire, Durham, NH.)

But all that said, I can watch television at home because I can put the sound down if necessary.

And if this fails, I listen to my Talking Books, which have all kinds of subjects. I can listen to poetry or essays or history with the lights off with my four dogs on the bed, and I am very, very happy.

I'm going to a meeting tomorrow in my wheelchair, and if I have to go to the bathroom, I have to have help, because most restrooms are not accessible for people who have disabilities. I don't talk about the ins and outs of this, but trust me, its true. People want to think that all of this has changed and the bathrooms are accessible and all of the sidewalks have curb cuts so you don't have to deal with a curb. NOT.

And I don't do as many things as I am able to do because of the complexity of managing the comings and goings.

I live alone and have people who help me. I have my groceries delivered. I have people help me with the housework. I have people who take me to the doctor, if I can make this happen—both coordinating and paying people to take me to the doctor. Many times I can't get someone to take me to the doctor for love or money.

So getting back to more interesting things. Many of my friends and I rescue animals, and we find good homes for them. When we see a dog that has been starved and beaten become a healthy, happy dog, it is a great experience. And I do gardening on my front porch. And like everyone else, I have a computer, and like everyone else, it is my link to the world.

I have most recently started working with people in the inner city. They have been giving Christmas parties for children for years. Last Christmas we got toys, books, tasty things to eat for 800 children. I was told that these presents might be the only ones the children would receive. This event was wonderful. I sat at a special Christmas gift table with books about animals and toys for the children's pets. I felt I was just exactly where I should be—with children who liked animals as much as I do. One little boy asked if I had any books about snakes, and luckily I did. He was delighted when he opened the present and said, "**SNAKES**!!!" There we were. The child. The snake book. And me. This was one of the happiest moments of my life.

I started to paint again, I laugh with my friends, I am lucky to have come this far.

I had the luck to meet Anna Deane Scott, who had the belief that there was always another way to do something. And indeed that was the case.

I met Maureen Neistadt, who asked me to speak to her OT students and show them my paintings.

I had my beloved trained seizure dog Timmy, who helped me to walk, stopped me from falling, made me feel safe. He was an incredible gift for me when I was frightened and lonely.

In the early years right after the accident, Dr. Thomas Glick, a neurologist, was important to me. He encouraged me, was kind to me, was generous with his time, and listened to my many, many tears. Dr. Glick was a remarkable man.

My Mother and Father in South Dakota kept me afloat financially and emotionally. They called me every day after day. I can't imagine what would have happened to me without their help, when I had next to nothing. They had been so proud of me—of my plays, my films—that had drawn honor and acclaim and added meaning to their lives. I knew what had happened to me had broken their hearts. I could hear it in their voices when they talked to me on the phone.

If I had lived 100 years ago or had been born in the third world, I would never have survived.

Instead here I am having the honor of talking to you.

And who am I now? I'm a human being. Just like everyone else.

POSTSCRIPT: THOUGHTS FOR OCCUPATIONAL THERAPY PRACTITIONERS

I have one final thought that I want to share with you. I have spent a lot of time thinking about what "helps" in the kind of situation I have been in with my brain injury. Why could some people get through to me and not others? Why did some people comfort and heal me and other seemingly well-meaning people shame or humiliate me? In other words: What works? What heals? What helps?

I discovered that power is at the heart of living with an injury, and power is at the heart of getting better. Many of us, particularly women, don't think of ourselves as having power. It is just a word, not something we own or think much about. Yet power is the ability to make things happen.

When I was at my most diminished, it felt as though everyone was more powerful than I was—from the secretary in the doctor's office who had to take the time to push the right elevator button for me to the cab driver I had to trust to give back the correct change because I could not count. The people who had to show me to the restroom when I was not capable of finding it. The doctors who filled out the insurance forms so that I would get disability payments to buy food and pay the rent. It was a very long list, and I was at the bottom. I had to depend on everyone.

Because of the power issues (who has it, who wants it, who needs it, who can share it), I think it is important to check why you are going into the healing professions. Ask yourself tough questions and keep asking them. Questions like "What do I get out of this work?" "How does this situation make me feel about myself?" "Do I need to have things in black and white or can I bear the

uncertainty of all the shades of gray that illness and sorrow present us with?" "Can I trust people, however damaged, to know what is best for themselves?"

So the question I am asking you is this: Can you give over power to another person? Can you honor their own wishes, dreams, abilities? Can you be as interested in their abilities as you are in their disabilities? Can you give them the tools to get their own lives back on track?

And do you listen to people? Do you *hear* what they are telling you? I believe that we are far wiser than we give ourselves or each other credit for. So I am telling you that the two most important things you can do as occupational therapy practitioners are to listen and to empower. The people who helped me the most did both of those things. I continue to bless them and to use what they have taught me every day.

Since I first started occupational therapy with Anna Deane in 1982, books have been written about brain injury, and classes have been given. There are whole hospitals for people with brain injury. Because of the war in Iraq, this is a new time for brain injury, and this is the time when you as occupational therapy practitioners are going to have to think new and think large—because there is such a desperate situation. I think it is a disgrace that every injured soldier might not receive occupational therapy. When I read that returning soldiers were not even evaluated for brain injury—it's like the Dark Ages. And so much suffering has been needless.

So then, dear friends who are reading this, I think your calling could be taking care of the soldiers who are coming back from the war. These are times to stand beside the soldiers and to advocate for them.

You have chosen a profession that helps, restores, teaches, and gives comfort. Some of the finest human beings I have ever met are occupational therapy practitioners. You speak for us, the people you serve. You are in our corner. You are needed. Each and every one of you is desperately needed. I am glad that you have chosen this profession. I am proud of you. Bless you. Bless you all.

ACKNOWLEDGMENT

Let me tell you about my friend Sally. Sally Schreiber-Cohn has helped me to make this chapter happen, from taking some of the original dictation when I was too sick to do it myself to bringing me art supplies for my painting. Sally and I were friends before the accident, and she has stayed my friend through these 28 years. Sally, an artist herself, stuck with me on a day-by-day basis, patient, kind, and worked to see that the artist in me did not die. She has always been in my corner.

Sally is a large part of why I came through all this.

He's Not Broken—He's Alex: Three Perspectives

12

ALEXANDER McINTOSH,
LAURIE McINTOSH, AND
LOU McINTOSH

In every lifetime, there are directions to take and choices to make. Each one of us carries a vision of our future. When something unexpected happens that takes us down an unfamiliar path, we have to adjust our vision and change our expectations while maintaining our self-identity. When parents discover that their child has a disability, they must adapt to this change and create a new vision for themselves and their child. This is the story of Alex, a person with cerebral palsy, told from three perspectives. Laurie, Alex's mother, begins the chapter. Then comes Lou, Alex's father. Alex has the last word, because it is his story that we want you to remember.

LAURIE

Before Alex was born, it had been easy to slip into fantasies of his future. I could picture him toddling around the deck of our sailboat. (I would have to remember to look into safety netting.) I would have to be careful to watch him around our home, which was also a boatyard. When he got old enough, we would get him his first toolbox and hand tools. He would bang his little toy hammer side by side with his dad while he worked on boats.

Alex was born twelve weeks before his due date. He weighed two pounds and needed all the medical support of the neonatal intensive care unit (NICU) to stay alive. Ten days after his birth, my husband Lou and I were ushered into the conference room near the nurses' station. I remember that the room was darkened. The shades had been drawn against the bright sunlight outside, and no one had turned on the lights. I was surprised to see that the social worker and the neonatologist were joining us—all the players. The neurologist was friendly but somber as he showed us pictures of Alex's latest brain ultrasound. As he used words like *periventricular leucomalacia,* I tried to swim to the surface by putting on my professional hat and being the

occupational therapist that I was trained to be. Yes, I knew all about spastic diplegia. He would have trouble moving his arms and legs. Of course, I could help explain this to my husband. Cognition would probably be undamaged. Well, that's something good. Of course, there is always the chance. . . . the brain does amazing things. I was in a fog as I left the room, trying to make sense of the news.

Lou and I walked back to Alex's isolette. We peered in at the uncomfortable little being who was still pulling at his feeding tube and now making a faint mewing sound. I put my hands through the portholes in the side of the box and stroked his arms down away from the tube. I couldn't get myself to talk to him. I stared at him but could not make sense of what I was seeing. Who was this new person? . . . "Spastic diplegia." Would he even walk? I couldn't picture anything. I left the hospital that day with an empty feeling. It was almost as if Alex had died.

However, Alex didn't die. He grew and changed. He developed a unique personality before he even left the NICU. When he finally came home, near the time of his due date, he seemed like a typical baby. I loved showing him off to people and telling them what a miracle baby he was. There were days when I completely forgot about the brain scan and pictured Alex as I had in my dreams before he was born. On other days I would panic over his inability to roll over or sit up. I would imagine him having to use a wheelchair or being unable to get a job. The part of Alex that was his future was completely cloudy to me. All I could do was focus on the Alex that was present.

Throughout Alex's youth, we repeatedly cycled through the stages of grieving. Once, when I was furious with a neurologist, I remembered reading about anger being one of the typical stages, along with denial, bargaining, guilt, and others. In my practice, I frequently heard health professionals scoffing about this parent being in denial or that parent "just going through the anger phase." They sounded so superior, as if they would never handle a situation like this in such an unhealthy manner. Had I been in denial about Alex? Sometimes. Was that a bad thing? Did that make me weak or neurotic? Absolutely not. Professionals who criticize parents for going through the stages of grieving should have a chance to try it themselves. Telling someone that she should not be in denial or not be angry is like trying to tell her to self-actualize. It is just not something that you can do on command.

Our best health professionals were those who listened carefully, recognized where we were coming from on any particular day, and accepted that that was the reality of the day. Some days I was optimistic, and on other days I didn't see how we could possibly manage. Some days I would be full of energy and ask for more exercises or suggestions for activities, and on other days I hid my head in shame because I had not done Alex's stretches faithfully. I was grateful to the professionals who could adapt to my changes and who were patient and knew when to push and when to rest.

As Alex developed into a little person, we began to be able to visualize his future. Our circle of friends began to include other families of children with disabilities. We attended support groups and special activities that were offered through our local agency. Lou began working on some national disabilities issues that brought him into contact with adults with disabilities who were making important changes in legislation. Lou and I were able to get advice from other parents and ask successful adults with disabilities what we should be doing to help Alex. It was this exposure to others in the disability community that allowed us to begin to picture Alex as a successful adult. My training and experience as an occupational therapist helped me to focus on creating a home environment with typical expectations. In my occupational therapy courses, I had learned how a person's habits, routines, attitudes, and values are rooted in the experiences of childhood. I wanted to make sure that Alex grew up with the habits, attitudes, and values that would make him a successful adult.

As Alex became a preschooler, I wanted to give him experiences that were as typical as possible. At this point, he was an incredibly verbal and imaginative child who used a tiny wheelchair. His left hand was nearly typical, but his right hand did not have skilled movements. He needed exercises to strengthen and stretch his legs and to improve his hand use. I found it much easier to embed therapeutic activities into our daily routines than to set aside special times to do "exercises." When I cooked meals, I would give Alex packages to open, mixtures to stir, and food to place in bowls. For example, I would chop green beans and put handfuls of chopped pieces on his tray so that he could place them in the pan. He helped me to fold and sort laundry. His specialty was matching socks. I gave him a radio-frequency remote control switch so that he could control electrical appliances such as the vacuum cleaner, the blender, the radio, or the Christmas tree lights. I supported him in standing at the kitchen sink so that he could "help" with the dishes. He loved washing the car with the hose. This kind of "work" was "play" for Alex. He often pretended to be an adult such as a chef, machine operator, or "car wash guy" as he performed these tasks.

I found out later, while doing research for my master's thesis, that preschoolers have a strong drive to imitate their caregivers. Not only are household chores motivating for young children, but they also help children to feel like part of the family. It is one of the first opportunities that children have to contribute and to feel gratified by helping others. By this point, Alex was in grade school, busy with homework and after-school activities and not as interested in helping me around the house. I wanted him to feel a sense of responsibility and to realize that he could be a person on whom other people depended.

Because of his physical limitations, it was difficult to find a task that he could do completely independently. I gave him the job of cleaning the bathroom sink. We soon discovered that he needed to wear an apron for this task to

keep the cleanser from getting all over his shirt. He became "Myrtle the Maid." It took several weeks to train him to do all the aspects of cleaning the sink. He had to learn to regulate the amount of cleaning powder that he poured out. He learned to hold the sponge at the correct angle to wipe the sink clean. He learned to work in an organized pattern so that he did not mess up an area that he had just cleaned. When he finished cleaning the sink, he would call me in for the "white glove" test to see whether I approved of his work. Alex was proud of his work, but that pride did not motivate him to clean the sink on his own. When I chose this task for him, I had to commit to never cleaning the sink myself. I needed him to understand that our family depended on him to do it. This was a challenge for me when we had company and I realized that the sink was not clean. I learned to warn Alex when company was coming so that he could clean it before they arrived. Lou and I put Post-it notes addressed to "Myrtle the Maid" on the mirror, asking her to please clean the sink. Alex took his responsibility seriously and, despite complaining, did his job well. After mastering sink cleaning, he moved on to toilet cleaning, dusting, and vacuuming.

Alex always managed to make household chores into something fun, but he did not like his daily living tasks, such as dressing himself. Alex started to realize that I was not really sure how much he could do on his own. He learned that if he had lots of difficulty with a task, I would probably finish it for him. Like any child, he would rather play than work, and putting on his clothes was work. I would watch him struggle with some part of dressing, trying over and over and getting more frustrated by the minute. We were always in a hurry, since everything took a long time for Alex. Inevitably, I would give up and rescue him. The next day, he would not have to struggle as hard to get me to help him because he was unconsciously training me to respond to his frustration and anger. All he had to do was get angry and frustrated sooner. Finally, I caught on to the pattern and decided to pick my battles carefully. On the weekends, when there was plenty of time, I would have him practice some aspect of dressing so that I knew that he could do it. Then, during the week, I would do all the parts of dressing that he had mastered and let him spend the time on the one skill that most needed practice. Some days, I would have him do only the parts of dressing that I knew he could do quickly. Only when there was plenty of time did I ask him to dress himself completely. Eventually, he put it all together and was able to dress himself, although it still took a long time and required lots of patience.

Lou and I knew the power of learned dependence, and we worked hard to create an environment in which Alex felt responsible for himself even when he needed help with some things. We tried to make sure that he felt the consequences of his choices. Behavior plans became part of our lives. For instance, in the mornings, Alex assumed that we would pack up all of his things, make his bed, put a coat on him, and send him out to the bus. At first, we had to help him with these things because they were physically difficult and time-consuming, but gradually, we tried to fade our assistance. Once we knew that he was capable of doing things on his own, we had to enforce that independence and make it part of his routine. For many years, he had to complete all the tasks on a checklist and get out to the bus on time in order to earn a reward. The reward for Alex was usually a book to read on the bus. Lou and I found that well-thought-out behavior plans worked for us as well as for Alex. We needed constant reminders to let him do things on his own and not jump in to help when things got a little tough.

As parents, we had a fairly good idea of what Alex's capabilities were at any particular time. It was much easier for Alex to take advantage of the well-meaning staff at school. People wanted to help him all the time, especially people in the cafeteria or the bus line. Every year, we had to meet with teachers and staff to explain to them how important it was for Alex to learn to think on his own. One late fall day when Alex was in middle school, I brought him back to school after a dentist appointment. After we checked in at the office, I told Alex to go to class and I would carry his backpack for him. I realized that Alex had no idea how to find his classroom. He had always had an aide or student carry his backpack, and he simply followed them. The next day, he came to school with a backpack on wheels so that he could pull it himself. However, he still had someone with him because there was a policy that a disabled student could not ride the elevator alone. It took a few phone calls to change the policy, and Alex was soon getting around the school completely independently.

Occupational therapy and physical therapy were available to Alex at school, but it was always difficult to balance therapies with academics. Alex was an extremely good student, and he wanted to be in the classroom as much as possible. In elementary school, he was seen outside the classroom for physical therapy, but occupational therapy was done on a consultation basis. Eventually, Alex's physical therapy was changed to a consultation model, which meant that he had to take more responsibility for his own stretching and exercises at home. By the time Alex was in high school, he was switched from an Individual Education Plan to a 504 plan because he did not require special education, merely modifications to regular education. Alex learned to advocate for himself by meeting with his teachers to adjust program requirements as needed. Assistive technology became a necessity in high school. Alex's handwriting and typing were slow, so he used a voice recognition program on the computer that converted his voice to text for taking notes and writing essays. He also found that a digital voice recorder was helpful for taking notes, recording assignments, and remembering tasks that needed to be done.

Recreation activities were another area that required thoughtful planning. My first instinct was to have Alex be

involved only in "typical" recreation activities for "typical" children. I did not want him to grow up feeling separate and different from other children. Alex took karate lessons and attended a karate day camp in the summer. He swam at the town pool and attended a theater/puppetry class. He even became a Cub Scout. All these activities were great for him, although they came at a cost. Even though the adults who were in charge of these activities had good intentions, they had difficulty planning the activities with Alex's skills in mind. I became his aide during many activities in order for him to be fully included. Field trips and special activities required special planning to make sure that accessibility was considered and that Alex would be able to stay with the group. We had a few disasters with trips to places that we thought would be accessible but were not or leaders who planned activities that were too physically demanding for him.

It was a great relief to relax my standards and allow Alex to try specialized recreation activities. He participated in adapted horseback riding, hand-cycling, wheelchair court sports, and adapted skiing (Figure 12.1). At these specialized programs, I did not have to worry about making modifications because everything was set up for children with disabilities. Volunteers and program leaders were trained to deal with everything from transfers to helping a child in the bathroom. At many of these programs, parents were able to drop their children off and pick them up two hours later. That was a new experience for me! When I did choose to stay, I loved being able to sit back and watch my child having a good time while I stayed on the sidelines and chatted with other parents. It felt so "normal." Alex enjoyed the camaraderie of being with other children who had similar challenges, and many of the friendships that began at these activities have lasted for years.

Preparing for Alex to go to college took a lot of planning and creativity. Alex decided that he wanted to be

within a three-hour drive of home, so we looked at colleges throughout the Northeast. Several of them were willing to accommodate students with disabilities but did not have much experience with this, and the campuses were not fully wheelchair accessible. Alex decided to attend a university near our home. This school had an access office, which coordinated accommodations for students with disabilities. He wanted to live on campus and have a typical college experience, including living on his own in a dorm. In the summer before he moved on campus, we checked out his dorm room, which had been carefully chosen to meet his needs. He spent several afternoons driving his new three-wheeled scooter around the campus and learning how to get through doors and operate elevators. Alex decided not to hire a personal care attendant even though it was still taking him over an hour to shower and dress in the morning. We carefully set up his room with a special stand for his reacher, sock-aide, and dressing stick. We bought a carpet for the room so that he could push his feet into his braces and shoes without having them slide. The dorm already had a fully equipped accessible shower. We purchased special shelves for the closet so that Alex could reach his supplies. We put up several plastic hooks to make it easier for him to hang his bathrobe and coat. A small folding shopping cart doubled as a hamper and a means of getting the laundry down to the laundry room. We practiced washing and folding laundry at a local laundromat during the summer.

The first few weeks of college were difficult for Lou and me as we waited at home to hear how things were going. Like many college students, Alex was enjoying being on his own and did not feel like calling home. When we finally heard from him, he was doing just fine. There had been a few problems with automatic doors not working, but Alex had contacted the right people to get things fixed. Crossing busy streets in his scooter had been a challenge at first, but he learned to use the crosswalks that were equipped with pedestrian signals. Lou and I were pleased to admit that we had passed the test. Alex was ready to be on his own. We had learned a lot as parents and made many mistakes along the way, but we knew that we had done some things right: Alex grew up feeling like a typical person who happened to have a physical disability. He knew that there were obstacles to overcome, but there were also people to help him when he asked for it. He knew that nothing is impossible and that there is always a way to modify and adapt things for success. He knew that he could help others and contribute to the world. Most of all, he learned that he was in charge of his own life.

LOU

When Alex was born, I suppose I was a typical new father in most respects. I didn't have a clear idea what fatherhood would be like. As far as I knew, dads were supposed to do

what they were told by moms, who somehow "just knew" all about babies and young children. I was sure I would be informed of my role when it was time for me to know. My pictures certainly didn't include the possibility that my own child might be born with special needs. I thought I would be playing catch with my six-year-old in a few years and arguing about access to the car in another few years. I hoped I would be an adequate dad and not let my child down.

So the news that Alex had an abnormal ultrasound scan and probable brain damage was completely outside my experience. I had no idea what to do. I had expected to be less important than Mom, but now I was irrelevant. Mom was an occupational therapist and had professional knowledge about disability. I didn't. There wasn't much that I could contribute to the family except for diaper changes and a paycheck.

I remember feeling utterly marginalized almost from the beginning. Doctors and nurses would talk to Mom, not to me. Mom got the pamphlets and lectures about how to care for Alex. When I went to an appointment with Alex, I was always asked gently whether Mom was planning to arrive later, or . . . ? After all, it was Mom's job to take care of this child, to know about disability, to learn about social services, to make appointments, and to make the decisions about Alex's care. So I began to act the part: I spent less time with my family, had a few too many beers in the evening, and began to hear everything that was said to me as a reproof or insult.

In the years since that time, I have learned that my experience was typical. New dads of children with special needs discover immediately that the world of children's services is focused on the moms. That's unfortunate, because for our own mental health, let alone our ability to support our families emotionally and financially, dads need recognition that their role extends beyond "making sure Mom is listened to" and "pinch hitting." We need recognition that a "dad" is not merely an inferior form of a "mom." (Of course, since so many of the physicians are male, so many of those males are patronizing and condescending, and so many of them seem to know almost nothing about the experience of disability except for the medical part, moms get marginalized in their children's care too and have their own horror stories to share. But I'm telling the dads' story.)

On the other hand, this marginalization can also be very important in allowing dads to think independently about their children's disabilities. One of my memories is about Alex's first pediatrician, who loved babies. When Alex first came home from the hospital, the doctor proudly carried him out and paraded him around the waiting room, exclaiming how perfect he was. But as Alex grew older and his legs and arms didn't work quite the same way as other children's, the doctor seemed to become more and more reluctant to deal with him. He assured Mom and me that our child was "going to be fine! He'll be just fine, you'll see!" When Alex was a year old and unable to roll over, let alone crawl, the doctor warned us that we needed to make sure every part of the house was childproofed. When Alex was three, still unable to stand up without assistance and able to walk only a few steps on crutches, the doctor lectured us about making sure to hold his hand so that he wouldn't dash out into traffic. The doctor even counseled me, "as one dad to another," that I must "not give up hope" about my son.

At last, during an office visit when Alex was four years old, I suddenly realized what was going on. This doctor loved *perfect* babies, but he regarded my "imperfect" son as a failure—a baby he hadn't managed to rescue completely from the results of prematurity, a child he needed to *fix.* I lost my temper and told the doctor that *despite* an inability to run out in traffic, my child was *already* fine, *and* he had cerebral palsy; and that I did not need *hope,* I needed *routine medical advice.* Since Alex wasn't *broken* and didn't need to be *fixed,* I felt that it was time the doctor stopped giving me warnings about dire possibilities that weren't possibilities at all for Alex.

After that experience, I began to notice that the medical and therapeutic worlds have a "broken/fixed" paradigm: "This limb *doesn't work* and we must *restore it to health."* That's fine for rehabilitation situations, but it doesn't fit the facts when we're talking about a child or adult who is *already just fine* and whose legs or arms don't work. As a Dad, I certainly want advice and support on how to make my child's movements more functional, but please don't waste my spirit or his self-esteem by trying to tell me he's *broken!* I know better: He is *absolutely fine,* just the way he is.

Families of children with disabilities often claim that our stress levels and divorce rates are higher than those of typical families. The data I have seen tend to suggest, surprisingly, that we're wrong about the divorce rates, but there's no doubt that we're right about the stress levels. The early years of parenting children with disabilities are a very lonely and challenging time for both parents, and dads have very few role models and not much support. It is especially difficult for dads to admit their own weakness. We don't always know how to seek support appropriately, and sometimes our ways of asking are not very clear. Sometimes they're abrupt, and sometimes they're scary. The result is that we antagonize the people from whom we need the most understanding and support. Like many other dads, I slipped into marginalization and irrelevance during Alex's first years of life, and I was very lucky to escape from the trap. The experiences that rescued me were the opportunities I had to contribute in a special way to Alex's life. Those experiences are the most important things I have to share with you, because they transformed my life.

One day when Alex was about three years old, his mom and I had our usual fight in which she accused me (correctly) of avoiding the family and spending hour after hour "playing" in the workshop instead of "doing a fair share." At the end, she said something like this:

I know you're going to just run away again and hide out in that shop; so while you're there, if you actually want to be useful, you could prove it by building something for Alex to sit on. It needs to be some kind of a chair, with a foot rest ten inches below the seat, and a seat depth of eleven inches, and a seat back with a couple of corner pieces to pull his scapulas forward and break up the hyperextension pattern. Oh, yes, and it needs a pommel so he can't arch out of it—and it needs a seat belt—and it would be *really nice* if you could make it light enough so that I could pick it up and move it—you always overbuild everything.

These were fightin' words, but Mom had grown up in a woodshop and was entitled to her opinion even if I didn't agree with it.

So I went out to the workshop, in a very sour mood, and sawed and fitted and fastened for a couple of hours and built a little portable seat with all the dimensions she had given me. It not only was portable, but also could actually be taken apart, and all the loose pieces could be stowed away underneath the chair. I was quite proud of my invention, although of course I was absolutely sure it wouldn't be appreciated.

I brought this creation into the house, and Mom carefully put Alex in the chair and positioned him at the kitchen table with some paper and a couple of crayons. To my utter astonishment, Alex picked up one of the crayons and began to color and draw on his paper independently—skills I had never seen him use before. There must be something good about this "proper positioning" I had been hearing about! Suddenly, I realized that I had actually done something that was directly, obviously related to making Alex successful in overcoming some of the effects of his disability. Perhaps I wasn't as utterly useless as I had thought (Figure 12.2).

Of course, there is a limit to how many chairs a dad can build before he runs out of baby butts to park in them, so if that was to be my only dad skill, I was still quite a useless fellow. But it was a good start, and I was lucky enough to be able to keep going. Within the next few years, I became an advocate not only for my own family, but also for others in the early intervention world. I developed an electronic network for families of special-needs children; I became part of a national committee to oversee early-intervention services for young children across the country; and eventually, I became a professional special education advocate. I know I would not have had any of these experiences if it weren't for that little chair and for the opportunity I was given, as a dad, to contribute to my child's life.

Today, as an advocate, I see moms and dads playing the same stereotyped roles that Alex's mom and I played when he was small. Mom keeps the records, Mom deals with the school folks and the doctors, and Mom goes to the meetings. There is often a feeling that if Dad goes to a meeting, there must be something wrong. Even today, most of
FIGURE 12.2   Alex sitting in his chair on the sailboat. (Photo courtesy of Laurie McIntosh.)

the people at educational team meetings are women, and Dad is not likely to feel welcome; in fact, he's often seen as a very scary person who doesn't understand how hard everyone is trying and who doesn't "know how to be reasonable." He is marginalized and excluded, sometimes kindly and sometimes out of fear and hostility, and Mom is left to deal with the child's disability without his assistance.

That is particularly unfortunate because we know from research that it is bad for the children. Longitudinal studies of children with disabilities have shown that family cohesion is one of the best predictors of good outcomes for children with disabilities (Hauser-Cram et al., 1999; Shonkoff & Philips, 2000). Any time we exclude dads from their children's lives or do anything to diminish dads' importance, we have a direct negative impact on those children's prospects for success in life.[1] If you care about the children, that is unacceptable.

---

[1]An excellent resource on father involvement is the Head Start Bureau's June 2004 Bulletin, *Father Involvement: Building Strong Programs for Strong Families,* available for download at http://www.headstartinfo.org/pdf/father_involvement.pdf.

At the same time, I have also learned to remember that Dad's job is to be a parent and Mom's job is also to be a parent. Neither Mom nor Dad needs to be a doctor, therapist, or teacher in order to have credibility. What we bring to the table as "mere parents" is sufficient, because we are the keepers of the dreams and visions for our children, and we will be their advocates and companions long after all their childhood caregivers and teachers have retired. Mom and Dad may *also* be professionals with titles and credentials and lots of education, but the most important hat we will ever wear is the Parent Hat.

ALEX

When I was about seven years old, I was firmly convinced that I was a werewolf. I had never actually undergone any physical transformation at the full of the moon, but seven-year-olds are not bothered by such trifles. The crowning touch was that my crutches acted as a second pair of legs, and although when wearing them I could never really manage a wolf-like lope, I made do instead with a sort of galloping skip. Nevertheless, it was fast enough (to me) to reinforce fantasies of running swiftly through the forest on silent paws, seeking unsuspecting prey.

The technical term for the condition of being a werewolf is *lycanthropy,* after the mythical Greek king Lycaon, whom the god Zeus transformed into a wolf as punishment for his tyranny. I knew the word at the age of seven, having read every book on werewolves that I could both find and understand. I was proud to declare myself a lycanthrope to everyone I met.

One day that year, my mother, my younger brother, and I attended a fund-raising boat race, the object of which was to allow wealthy yacht owners to raise money for the disabled. I was skipping around the lobby of the yacht club where the event was being held, giving long, mournful, ear-splitting howls, as a proper werewolf should. Mom was over in a corner with my brother, trying to pretend that I was someone else's child.

One of the yacht owners saw me, and she said, "Look at you, doing so well. What's your disability, honey?"

"I have lycanthropy!" I said, beaming.

A few minutes later, she was chatting with my mother and said, "I just met your son. What a nice boy. It's so sad that he has lycanthropy."

Mom smirked. "Um, I think there's something you should know . . ."

That is what happens to people who are lacking in disability awareness.

When I was about fifteen, I decided to try my hand at metalwork. My father has a workshop next to the house, and he found me the gloves, jacket, goggles, and apron necessary for working with heated metal. My primary objective during my first experiment was to make a three-inch-long model sword out of nails.

I learned how to manage a coal fire those first few days and, later, a propane blowtorch. I learned not to leave a nail in the fire for more than a minute or two for fear of burning the metal and that heat dissipates very quickly from a nail after it has been taken out of the fire. I also learned (the hard way) that just because a nail isn't glowing red anymore doesn't mean that it's not hot enough to burn flesh through a glove.

Because I had to strike the nail quickly while the heat was retained, there was a great deal of tension in my hands when I was hammering. My cerebral palsy kept the muscles in my hands rather tight to begin with. Try as I might, I couldn't strike the metal at the right angles to make an even, straight blade or hilt. The nails kept twisting into a corkscrew shape. What I ended up having to do was hammer out the rough shapes as best I could, quench them (dunk them in a bucket of water to cool them), take them out of the vice grips I held them in and clamp them in a vice, then use the vice grips to straighten the twisted parts (Figure 12.3).

Sometimes the twists were so subtle that I could barely see them. In these instances, I had to make very small, precise movements with my hands, which are difficult enough even for those who don't have cerebral palsy. I often didn't affect the metal at all, and I even more often overshot the mark and twisted it more than it had been originally. I am still learning this skill; I have a long way to go before I can correct subtle flaws in metal.

My father says that the minds of people who have learned to use tools and build things work in a fundamentally different way from other people's minds. Builders' minds have a better combination of practicality and creativity, and they are better able to analyze a problem and come up with a solution. As I become more involved in metalwork, I hope I begin to think this way as well (Figure 12.4).

I have been involved in the Maine Handicapped Skiing Program since I was six years old. During most of my

FIGURE 12.3 Alex engaged in metal working. (Photo courtesy of Laurie McIntosh.)

FIGURE 12.4 Alex and his dad doing metal work in the boatyard. (Photo courtesy of Laurie McIntosh.)

time there (twice-monthly lessons from January through March each year), I used normal skis combined with out-riggers, devices that resemble crutches with skis attached. I used the same ground for each lesson: the end of a trail right outside the Maine Handicapped Skiing lodge.

I learned very quickly that there is nothing so apt to make one acutely aware of one's own body as the fear of crashing into something. I have learned to use this aware-ness to judge turns and to move my legs, skis, and outrig-gers in just the right way to make myself stop. However, in eleven of my twelve years of skiing, my ability to turn came and went.

When I used the outriggers, I had to put a great deal of weight on my arms to hold myself upright on the snow. This did not leave me free to put as much weight on my skis as I needed to turn at will and in the direction I chose. Therefore, my ability to turn on any given day depended largely on how willing I was to take the weight off my arms and, to my mind, increase the risk of falling.

This past year, I tried a new method, using skis and a device called a slider, patterned on the walkers used by the elderly. The slider acts as a support system for my upper body, leaving me free to shift the weight on my legs as needed. I am also tethered to one of my ski instructors, who helps me slow down on especially steep slopes.

With the help of the slider-and-tether system, I am able to travel farther on ski trails than I did in all my eleven previous years of skiing. I can maneuver through rough terrain. In consequence, I believe I am even more in con-trol of my body.

In elementary school and high school, gym class was seldom a productive time for me. This fact hinged on my not being able to run. I used crutches rather than a wheel-chair at school. Although the instructor sensibly assigned me the position of flag keeper in games of capture-the-flag, the members of the opposing team who ran past me were always just a little too far away for me to reach out and tag them, which was extremely frustrating. I must admit that sometimes my inability to tag people had more to do with my attention span than my disability.

There were instances in which my teachers came up with creative modifications to such activities, but these were so few and far between that I cannot now clearly recall them. Most of the time, my participation in such games consisted chiefly of my hopping around on my crutches while everyone else ran and making the motions of what the other students were doing. I probably looked ridiculous.

The exception was baseball. I never learned the rules of the game quite as well as my peers, but I could bat as well as anyone in my class. When it came time to run the bases, either I had someone else represent me or my opponent was required to hop on one foot to even the odds.

On the whole, I am glad I no longer have to take physical education courses.

I have recently enrolled at a state university, which is ten minutes away from my hometown. The process of moving in began with evaluating the accessibility of my dorm: the ease or difficulty of entering and moving around the rooms in an electric scooter and on foot and the acces-sibility of the bathrooms, laundry room, and lounge areas. Even though we went to the dorm in the summer to see how everything would work, it still took me a while to get used to the new routines once school actually started. I had to remember to grab my little bucket of bathroom sup-plies before heading down the hall to the bathroom. My schedule now had to include time to get to the dining hall for meals and time to do laundry on the weekends. In short, I had to plan ahead for almost everything.

One of the biggest challenges for me was learning to find my way around the campus. I think that my lack of mobility as a child kept me from learning some fundamen-tal lessons about directions. When I was a young child, I was pushed long distances in a wheelchair, and the dis-tances I walked were very short. I was never left on my own to find my way around because of safety issues. As a teenager, I would go for walks in my neighborhood, but it was a familiar area, and I usually just walked around the block.

The summer before I went to high school, my mother took me to the empty building to practice my routes at least three times before I felt secure. When I arrived on the uni-versity campus, I realized that I had a very poor aptitude for map reading. I had no idea how to get from one place to another by looking at a map. Even when I asked people for directions, I would often have to ask several other peo-ple along the way before I found my destination. Since I got my new three-wheeled electric scooter right before school started, I had not had much opportunity to practice driving it. I was not a car driver and had never had a power vehi-cle. Most of the time, I managed to get places without ruin-ing too much sheetrock or crushing too many toes. Small elevators were a challenge, as was maneuvering in the

crowded dining hall without knocking over piles of dishes and spilling drinks. The automatic doors for the buildings on campus usually worked, but there were always a few that were out of commission. Sometimes I would be lucky enough to find someone to hold the door for me, but I soon learned to hold the door open with one hand while driving the scooter through with the other. Since my door-holding hand is weak, I fear that I may have left some scratches on a few doors. The most difficult problem was parking on the shuttle buses. They were accessible and had lovely ramps, but once inside, I found myself required to parallel park in a specific and confined spot in order for my scooter to be properly tied down. I wished I had had scooter-driving lessons in high school.

My dorm is set up with automatic doors that have remote controls. Students with mobility problems are given small remote control units to attach to our key rings. It gives me such a great sense of power to approach the dorm door at full speed, push the little button and cruise right in without even stopping. Of course, I do this only when there is no one around to run over. Other students stand at the door and fumble for their identification cards in order to run them through the door-opening machine. Most of the other students don't know that I have this remote control device, so I can "magically" open the doors for attractive girls when I'm twenty feet away.

Given that I am late for class more often than I would like (because my morning routine always takes longer than I plan for), I often have to drive my scooter very quickly across the campus. This sometimes proves to be unsafe. At one point, I was racing toward the building in which my class was taking place, and my overfull backpack, hanging on the back of my scooter, caused the scooter to tip sideways. I crashed onto the concrete path, swearing inaudibly but profusely. Fortunately, the noise attracted the attention of two kindhearted passersby, who helped me to my feet and also laboriously got the scooter right side up again. Since that time, I have been more careful to carry less weight in my backpack and take the corners more slowly (Figure 12.5).

The university has been good about making sure that my classes are all held in wheelchair-accessible rooms. There is an access office that coordinates all the services and modifications for students with disabilities. They move classes to accessible rooms for specific students. The access office also coordinates student note takers so that students with disabilities can have other students take notes for them. The note takers never know which student in their class is receiving their notes. The note takers deliver the notes to the access office, and the notes are distributed to the students who need them. At this university, the accommodations that are listed on the student's high school Individual Education Plans or 504 plans are respected. For instance, in high school, I was allowed to have extra time to take tests, and I have the same accommodation at the university.

FIGURE 12.5   Alex going to classes on campus. (Photo courtesy of Lisa Nugent, Photographic Services, University of New Hampshire.)

As buildings on campus are renovated, they are made accessible. Unfortunately, the English Department building has not been renovated yet, and since I am majoring in English, this has presented some problems. The department offices, including my advisor's office, are up a flight of stairs. If I need to pick up forms or drop things off, I call on my cell phone, and someone comes downstairs. If I want to see my advisor I have to e-mail her to set up a specific appointment because I can't just show up during her office hours or drop by to see whether she's in. So far this system seems to work, although it is just one more way in which my life requires more planning.

The teachers and students on campus treat me just like any other student. It is obvious that this school is used to students with disabilities because the community is very accepting. I don't feel patronized or disrespected at all. My teachers expect the same work from me that they would get from someone else except that they are nice enough to give me more time to do it. There are a number of students with various disabilities on the campus, and we all just seem to fit in like anyone else.

CONCLUSION

Many people, including many new parents of children with disabilities, assume that a disability is like a shadow that hangs over a child's life, forever reminding him or her of things that cannot be done or achieved. As my behavior during the Lycanthropy Incident proved, I couldn't have cared less, as a child, about my disability in terms of what it prevented me from doing. I was just having fun and living my own life. I was able to do this freely because of what my parents learned, and taught to me, when I was growing up: *I am not broken; I don't need to be fixed.* Knowing this, I was, and am, able to choose who and what to be: werewolf, blacksmith, skier, college student, writer. The list is still being added to.

QUESTIONS FROM ALEX

1. What did you expect to find in this chapter? How did it meet, or differ from, your expectations?
2. Can you recall any instance in which the actions of someone with a disability contradicted your assumptions about how that person was going to behave?
3. List some common stereotypes about people with disabilities, and identify information in this chapter that negates those stereotypes.
4. Imagine for a moment that you have been in a horrible accident and your legs have had to be amputated. Brainstorm some modifications to your favorite (physical) recreational activity that will enable you to keep doing it.
5. Research currently available examples of what you came up with in Question 4. What are the similarities and differences between these and your own ideas? Have you come up with something that you think is innovative? If so, why are you still doing this exercise instead of promoting your idea?

QUESTIONS FROM LOU

1. To have a successful and fulfilling role in the life of a child with a disability, each family member needs to have the opportunity to contribute to that child's quality of life. Assigning "homework" is not the same thing and can be very damaging to the family. What is the difference? How can the occupational therapist's intervention support the creation of opportunities instead of the mere assignment of tasks?
2. What can an occupational therapist do to support family cohesion, and why is it important to the child?

3. In this chapter, Alex's father says that "Alex wasn't *broken* and didn't need to be *fixed*." How would you reconcile this perspective with the rehabilitation model of service? Can you reconcile it with the model of human occupation or another occupational therapy model? Why or why not?
4. Parents and siblings of a child with a disability often have no knowledge of occupational therapy and no understanding of why therapeutic interventions are necessary. Yet these "mere parents" bring a vital perspective to the planning process. What is that perspective, and how should the occupational therapist integrate that perspective into the child's treatment plan?

QUESTIONS FROM LAURIE

1. Learned dependence can be a more serious disability than cerebral palsy. People who never learn to be responsible for themselves might need assistance for the rest of their lives. How can occupational therapists prevent situations that lead to learned dependence?
2. We used household chores to give Alex a sense of responsibility and an important role in the family. What can occupational therapists do to help parents find useful roles for their children with disabilities?
3. We made sure that all the necessary modifications were in place for Alex to live in a dorm and attend classes at the university. Should some of this have been the responsibility of the high school occupational therapist as part of Alex's transition plan? Why or why not?
4. What was the difference in how Alex felt about himself in physical education classes versus handicapped skiing? How could his physical education classes been set up differently so that he felt better about himself?

QUESTIONS FROM THE EDITOR

1. This chapter presents three perspectives of Alex's life. How do these perspectives differ, and why is it important to have an appreciation of each perspective?

While Focusing on Recovery I Forgot to Get a Life

GLORIA DICKERSON

13

Hello! My name is Gloria. I am a fifty-four year old Black woman living in Boston. Most of my life, I have meandered along within the bubble of mental health treatment under a variety of designated attributes of being ill. To date, my sole primary and trusted relationships have been with providers of health services. At age 15, I was introduced to the mental health system as a patient. Now I look back and revisit my journey through a life of treatment in the light of today. From this vantage point, my life seems to have been an initiation into the land of never good enough, never quite arrived, filled with cyclical pain-filled struggles and some rays of sun. My birth seems to have hurled me into a predesignated life sentence of less than and a never-ending journey of repetitive bouts of trying to rise.

I have endured a life of injustice and mistreatment that was made bearable by my religious upbringing and years of therapy. My religious upbringing was both extremely painful and exquisitely inspiring. The deep, profound hope that is imbedded in the words and concepts of the Black Church and Bible gave me a foundation of hope that serves as a compass and, although sorely tested, has never been destroyed. The idea that we are all connected, obligated, and encompassed in a mission greater than each of us gives my life purpose and meaning. I have tried to turn away from my faith and connectedness many times, but life always brought me back to center.

In addition to religion, therapy is a primary source for hope in the goodness of people, for staying alive, and for trying to find a way to live well. The expert help of my therapist has helped to reduce the effects of parental mistreatment, torture, and sexual and physical abuse. Effective therapy is only as good as the quality of the relationship between the therapist and the consumer, paired with a "goodness of fit" between the need of the consumer and the specific therapeutic tools utilized. My therapy was effective or "good" only when there was collaboration between my therapist and myself. My most effective therapist knew the difference between her intention to help and my perception of being helped. She understood that my perception of being helped is a subjective state of feeling helped that can be discerned only by me.

My therapist is extremely respectful. She knows that any attempts to help me must be based on my stated wishes, desires, and needs. She allows me to choose, to take risks, and sometimes even to fail. The intention to "help," "being helpful," or "giving help" is only one part of the helping process. The "end" of the helping process is achieved when the person being helped feels "helped." The ability to make choices has been critical to my relearning skills of self-reliance and safety when engaging with others. Engagement and building trust have always been elusive concepts. For me, trusting a therapist begins for me with warm greetings, kindness, and acknowledgment of my rights as an adult. I can endure conflicts, misgivings, errors, hurts, and slights if I feel connected and valued as an adult.

There are some basic and essential qualities of all effective therapists regardless of theoretical orientation. Therapists must like people, access the ability to personally censor, be curious, respect difference, create a repertoire of skills, and have the ability to maintain commitment over time. Therapists must learn to acknowledge personal biases, avoid harm, and use their personal self knowledge to educate for change. Skilled therapists use all of their knowledge, skills, and personal gifts and deficits gleaned from their own life journey and operate from the position of being a change agent and healer. It is not enough to be correct theoretically. Therapists must be skilled human beings who care about and like others. The therapists I love have all these qualities. My therapy, though freeing, was very concentrated and focused. Unfortunately for me, all of us forgot one little thing: a therapeutic relationship is an assist to learning to establish other relationships that become a source of primary sustenance. Therapeutic relationships should never become a substitute for intimate, loving family and friends.

Life is bigger than the therapy relationship. Stabilization and maintenance are great goals to awaken hurt souls. However, once an individual grasps and mourns the losses and pain that brought her or him into therapy, then what? We need to remember that the primary pain associated with having severe mental illness and trauma often comes out of failed and abusive relationships. My primary "disconnect" emerged over time. Like a stealth bomber, silent at first, it soared in the night and then swooped down, blowing my insides into shards, simply changing the course of my life forever

My first years in the South as a young girl were riddled with incidents of trauma. I consider myself to be a Southerner because, up to the age of 5, my ancestral roots, my psyche and consciousness spring from events that occurred within a small town in Alabama. The family relationships and life in this small town caused essential disconnections within myself, with others, and with the world. My experiences include parental abuse resulting in the birth of my daughter, long inpatient stays in mental hospitals, graduation from college, more hospital-izations, suicide attempts, five different postcollege graduate programs, work throughout the human services field, and 39 years of therapy. These are only a few of the most influential and important experiences that dot the course of my life.

In this writing, I am going to tell you about who I am and where I have been. I will attempt to explain how I learned who I was and how this has affected every aspect of my being, from my excess weight to my choices of occupations and even to my dress. My present gifts and my abilities, my pain and my hope, as well as my deficits and despair, can be traced back to events during the first few years of my life. As with everyone on the planet, every event and experience, good or bad, has shaped me and culminated in making me the person that I am. After learning the facts of my life, people who have come to know me are surprised and astonished that I have survived with my intellect and hope intact. After hearing what I have lived through, most people react with jaw-dropping awareness and awe and silence. As people get to know me, they recognize that my life has been filled with extreme horror and that my endurance and survival are amazing.

I begin with accounts of memories about my family of origin and my early years. For years, I was the only girl child of my parents. My daddy (James) was born in 1925. My ma (Stella) was born in 1927. My brother Andrew is one year older and was born in 1949. I was the oldest girl and was born in 1951. My brother Roger was born 11 months later, in 1952. We often joked that this close proximity in our birth made us almost twins. We have always felt closest to each other. My brother Junior was born in July 1953, and he was the baby for many years. My brother Donnie was born in 1955. He died tragically and suddenly, and his existence has been erased from all family accounts. My sister Daisy was born in 1958. Her birth was my dream come true. I always thought she was a personal gift from God. Her choice to become and to remain estranged from me has been one of the greatest losses of my life. My brother George was born in 1962. Amazingly, he still fails to be recognized as a valued and independent person by my family system. My brother David was born in 1967. Although he is nearly 40, his life continues to affirm his status as my mom's "baby." As a Black man with untreated dyslexia, he makes do and escapes all aspects of being an adult, except procreation, and he lives without income on his relationships with others.

As for most of our neighbors, Black and White, life in the South meant Sundays in church, life as a sharecropper, and extremes of joy, violence, calmness, and pain. The residues of lives touched by violent, chaotic nights and the hard-fought-for appearance of calm, peaceful days set the stage for a culture of fear. The minister was pivotal in helping individuals caught in the maze of violence find meaning and maintain hope necessary for endurance. There are at least two types of ministers. Some ministers believe in, are motivated by, and love

"God" and all the things that a good "God" stands for. A minister operating from powerful needs to nurture "a loving and hopeful life-affirming world" will make mistakes, but her or his intention is to promote relationships between people that rest on ideals of love and hope. The conscious actions of a good minister start from deep-seated basic beliefs such as "Love your neighbor as you would yourself" and "Do no intentional harm." Other ministers beam out their fears of confronting feelings and thoughts that they deem evil and project negative intentions and motivations onto others. My grandfather was the second type: a fire-and-brimstone type minister. He could not have designed a better-suited context (the ministry) in which he could hide and insinuate his personal brand of fear and pain. Under the cover of the prevailing myths of goodness, high praise, and quality attributes of a "Minister," he operated unquestioned. He could do no wrong. His motives were never questioned. His actions were revered. His destruction is immeasurable.

My mother's and my father's children can be understood by looking at my parents' life context. Knowing how we learned to be the people we are is not an excuse for our failures and our deficits. It teaches us how to make meaning and find understanding. The meanings we make tell us how to understand our "self," others, and our relationships in the world. This is the foundation from which we begin to act or not act, choose or not choose, know or not know. We learn what it is to be a human being early. We learn about relationships from those around us. We learn what is important, what our value is, and what is right and what is wrong from our early relationships. They form the lens through which we see and know everything. What follows are some of the experiences that make up my lens. This is my beginning.

My mother was 23 years old and my father 25 years old when I was born. My mother tells a story about my birth and early days of life that has been critical to forming my vision of myself, my character, and my strength that has at different times both supported and diminished my assessment of my worth in my own eyes. I have heard this story since . . . well . . . the beginning. She said,

> When you were born, you weighed 4 pounds and 10 ounces. Your father came to see you. He said you were so small that he was scared to hold you. When he first saw you he looked at you and said, "God, she's so hairy and looks just like a little rat." And while you were in the hospital you lost down to three pounds. Everyone thought you were going to die. You stayed in the hospital for one month in a makeshift incubator. Dr. Everage was so good. He made an incubator from odds and ends and pumped oxygen into it to keep you alive. But you were not gaining weight so they sent you home. I think they thought you were going to die. I was so scared and I put you in a dresser drawer with a hot water bottle. I had to stay up all night with you and

> I kept pinching you to make you cry because I was so afraid you were going to die. I had to struggle and work so hard to keep you alive. You put me through so much.

My mother has reminded me of this story periodically and with precision throughout my life, reiterating the fact that my father thought I looked like a rat and keeping the wounds of this image alive and potent. Her pronouncements of her great sacrifice and the extreme imposition and burden of my birth have weighed heavily and occasionally tipped the scales in favor of trying to secure my early demise through serious suicide attempts. Often, to make a point during times I "got too big for my britches" or became "too full of myself" by thinking that I was smart or worthy of high praise or love, she would remind me of my botched entrance into the world, reducing me to the reality of her perception that I was "filthy and less than dirt." Her spiel often concluded with pronouncements that the debt I owed her could never be repaid and I was lucky to be alive. The picture my mother painted about how she and my father greeted me and her feelings about me combine with the full weight of subsequent events leave me with profound feelings of guilt and terror and periods of dissociated pain and thoughts that plunged me into depths of despair and my own personal brand of hell all my life.

My mother's family worked as sharecroppers on a farm in Alabama in 1954. My grandfathers on both sides of the family were ministers. As a minister's family, we had some social status among other poor Black families in the area. Yet my grandmother's predicament seemed to be no different from that of other Black women in the area. Most of the women of the South lived as silent subjects in the land of domineering husbands. But Black women that I grew up with had the additional burden of being alternately longed for, sexually desired, while at the same time their essence as beings was despised, sometimes by their husbands and most of the time by all men and women within this slice of society. I learned at a very early age that a woman's safety depended on the repertoire of defensive maneuvers of women and on the emotional state, whims, and actions of men. Unfortunately for my mom, she grew up with men who became enraged and physically abusive to any woman who dared think and act as if she was as intelligent and entitled to rights as any other human being, particularly a man. My mom tells stories that show her radical insistence on saying what she wanted, when she wanted, relentlessly voicing her opinions and naming what was unacceptable. To my great despair, her tales of bravery often concluded with epic depictions of her getting "beat down to the ground." Yet to my amazement, she took great delight in the struggle— in the standing up. The defeat seemed to be incidental. The pride she beamed out every time she tossed her head back and recounted her defiance, blow after blow, left its mark on my heart and mind. I resonate with her physical

strength and resilience but mostly with her pride of being defiant. This defying of "the beat down" reminds me that I come from a long line of survivors. The need to fight injustice has often thrilled me, motivated me. Overall, my mother's life taught her that she was inferior. She learned that her pain and terror were caused because she was Black and a female. Depending on the context, her Blackness or her womanhood or both got her mercilessly victimized. She had to endure, cajole her way out of, and fight against rape and verbal and physical assault from early childhood by her father, brother, and other male relatives. Later, as a woman, she entered the world of having to fight off White men in the households where she worked. These are the things that infiltrated my mother's heart, made my mother who she was, and caused her to hate that which came from her: her first-born girl.

It is as if every time my mother looked at me, she saw a girl with all the qualities and characteristics that she imagined that every person saw that led them to hurt and hate her. My face was a mirror. She looked into my face at one week, at one year, and for the rest of my life, and she could only see the vile, filthy little girl that got her beat and brutalized and kept her from the life she wanted. I have always felt hated by my mother. I could see that when she looked at me, she felt tremendous hatred and rage. There was no escaping the consequence of my meaning for her. I was everything that she thought others saw that made them hurt her. And I was gonna pay!

The life context in which my family lived overwhelmed their human potential and capacity for being hopeful. In this context, their actions can be understood, though it can never be a justification. The context shows how I learned to make meanings that sustain my life throughout recovery from devastating and unimaginably hurtful events in my life.

The phrase *keeping time in chaos* adequately describes my life during and for years after the emergence of my mental illness. My first five years of daily life in the South contained moments of exquisite pleasure, of running through the fields, pulling up peanuts when I wanted, and finding buried treasure by digging deep in the ground and pulling up unsuspecting sweet potatoes or carrots. Sitting by the water at one of the only swimming and fishing areas near our house, I often watched ants. My eyes went back and forth as I followed them as they went scurrying. I remembered wondering what could they possibly be thinking about.

I have always settled for the basic tenets of life, making lemonade out of lemons. Knowing that I missed out on love from a family and from friends, I lacked a viable self that is based on knowing that one is safe and loved. I am left knowing that I substituted therapy for a life and therapeutic relationships for love. My having a mental illness, PTSD and depression, could not have been avoided. Life circumstances and early relationships made this inevitable. I was lucky and unlucky—lucky because I got mental

health treatment. I was unlucky because my disorders are PTSD and dissociative identity disorder (DID). The emergence of DID was a lifesaving technique. I learned that I could live through overwhelming experiences by "turning around inside myself," and soon I had a host of friends and loved ones of my own creations. Having DID allowed me to compartmentalize my life—the tasks, developmental stages, reactions, feelings, thoughts, and reality. I learned to put away what I could not deal with so that I could get through the day and keep functioning with a modicum of sanity. DID, my prize possession, was a great skill. I could, in my mind, change myself to fit any situation, provide for other people's needs, avoid threats, and as for the chameleon, change was a great tool for functioning.

This survival technique, like all maneuvers to change reality, became a doubled-edged sword. The downside of dissociation, like all actions to change internal states by various techniques of avoidance, was that it took on a life of its own. My "functioning" was based on "magical thinking" and the appearance of functioning well. Changing my state by magical thinking replaces my adult consciousness with a child's-eye view, a child's reactions and a child's feelings, which are out of place. Yesterday's solution is a barrier now. Along with magical shifts in my consciousness come the pain and horror images, thoughts and feelings, and my deep immersion in "memory hell." Being in memory hell is like being locked in a closet full of feelings and thought patterns from the most torturous times in my life. Themes of abandonment, terrors, humiliations, pain-filled body states, and loss fill my vision and cloud my judgment. I walk through life in a 54-year-old body pretending— pretending so well that even I am not aware of the incongruence between being 54 and acting like I am 5 years old.

As a young adult, I had only a few vague recollections about my past. I never knew when or how my dissociation began. Even a month ago, I did not understand the implication of my trauma reaction and how it affected my perceptions, thoughts, feelings, and daily life. I have great shame and humiliation about being in a 54-year-old body with no ability to monitor elapses in time and no way to place things in chronological order. When asked to remember when an event occurred, confusion and embarrassment erupt, and I usually respond by saying, "Well, I believe it was a couple of weeks ago." Often, I wake up to find that I have been able to justify using an abusive tone and questioning of my allies' commitment, integrity, and moral stance because I was triggered.

The ability to divide my consciousness and convince myself that the shift is real began early in my life. I remember witnessing my brother getting shot by my mother. Later, I saw the rape and brutal murder of my best friend. I experienced sexual abuse and torture at the hands of my mother and father. I witnessed the lynching of my uncle. This all occurred before I turned 6 years old. After my baby brother was killed, before my friend died, and before my uncle was killed, my family left our home in Birmingham.

We went to live in my grandfather's home in Alabama. I believe my family was running away from questions about the death of my baby brother.

Life had started over. My brothers, my parents, and I never mentioned the name or existence of my brother again. I became best friends with a little white girl, named Paula. We both knew that we could never be seen together. One day, we were playing in the barn, and Paula, my best friend in the world, was killed. Her slaying was brutal, and today my mother's words still haunt me: "See what happens to your friends." I have come to believe that her death occurred because she was White and a needed target for sexual abuse. After Paula was killed, one night while sleeping, I was awakened by yelling and loud bangs on the door. My family was hauled out into the dark and beaten. I was raped before my family. My uncle was tortured and lynched and eviscerated. My heart was broken as a child. As an adult, I get to relive every gut-wrenching episode, try to metabolize that pain, and free myself from the memory by knowing what it was like through the repetition compulsion and then the frantic attempts to undo that come with hypervigilance.

I believe that the level of trauma my parents experienced and their demoralization are directly responsible for the abuse they heaped on my siblings, on me, and on others in their world. My father and mother gave words to high spiritual values and had a core work ethic that informed them. My father worked in construction, and my mother worked as a presser in a laundry and, in her later life, as a home health aide. My mother demonstrated that maintaining your life is the prime task of life. I am a survivor, and I come from a long line of survivors. We survived physically—some of us with hope and love intact but most often not. Like other victims of racism and genocide, I believed that traumatic and abusive relationships were the only model of how to live. Racism and postslavery oppression created a caustic environment, showing my parents that hope for a better future and rights of Americans to full citizenship seemed bound to remain a theoretical illusion simply because of the color of their skin. The illusion of freedom and acceptance of all within society made the reality all the harder to bear. Like a knife twisting and distorting their soul, words of freedom, equality, and acceptance remained great high-sounding values that never seemed to make their way into their lives.

I came to Boston when I was approaching my sixth birthday, leaving behind my maternal stepgrandmother. On arriving in Boston, I became more immersed in living in my head, because I believed that my stepgrandmother was all that stood between my death and me. When I entered school, I lost all hope of being safe in the world. School was terrifying because I was never allowed to be around White people in the South, especially after the murder of my best friend on the farm where my grandfather was a sharecropper. Terror interfered with my functioning as I entered school and I saw my teachers and met the principal. They were all White people, and all the kids were Black.

I was basically nonverbal but had a great imagination. Living in my head created an oasis from chaos, terror, and pain created by adults who were sexually abusive and often enraged for reasons that I could not understand. During September of that year, I heard my birth name, "Gloria," for the first time when my mother took me to kindergarten. On entering kindergarten, I already knew how to write my name. My older brother taught me how to make letters and write my name. He was teaching me that the letters meant something. He would say, "Now Fay," because they all called me "Fay," "make a straight line down, like a pole. Now, make a line on the top of the pole like a hat. That is how you make a 'T.' " I learned to hate messing up because my brother was good at everything. My mother loved everything he did. My father liked what he did. My grandparents thought he was so smart. He was everything to all of them. After all, he was lucky. He was a boy. The difference between how my mother looked at him and how she looked at me made me work harder to overcome my primordial defect of being a girl. So I learned I would have to work extra hard to be liked, to become, to finally deserve to be alive. My prized secrets were that I really was better than my brother and that I could do anything as well as my older brother and any boy or man. This notion that I was deemed inferior by all those I loved was critical to my development. I have lived a life of striving and overcoming. I was going to show everyone that I was as good as a boy. Anyone who stated or indicated in any way that I was inferior to a boy because of my gender could count on my angry protestation. Any authority figure making such accusations could count on my secret retribution for what I felt was a most heinous assault against my very being. I tried to do everything that a boy could do. I rebelled against my lot in life because of the unalterable fact that I happened to be a girl.

As the teacher discovered my skills, she made a decision, and I was placed in first grade. Then the tide turned. The teacher's enthrallment with my gifts was short-lived, and I was demoted and returned to kindergarten. This event precipitated seeds of doubt about my intelligence that has followed me all my life. It is not every child who can say she or he was demoted in first grade. My teacher's explanation was that I was extremely "immature." My persistent hysterical crying, flailing about, and screams for my mother led them to conclude that I was very babyish. This first entry into school began to show that my sorrow and pain were deeply entrenched.

When I was 15, my mother and father fought over money, accusations of extramarital affairs, infidelity, and alcohol-related distress. They also fought over my father's excessive attention and sexual abuse of me. I had been an A student, and up until age 15, I had found school to be a sanctuary. At 15, I became terrified of school. I slept little. During the night, I would literally run out of my house to

Boston City Hospital. I would sit in the lounge area with sick people who were waiting to see a doctor. I only went to the hospital because I was aware that as a young girl on the streets of Boston, I was still unprotected prey. Every night for months, I ran away after becoming frightened while trying to sleep. Each night, I envisioned that as soon as I fell asleep, a man would come and stand over me. He would wait until my sleep was deep, and when terror peaked and fear of surprise imminent, I knew he would spring upon me. I knew as sure as I can see the words on this page that he would end my life in torturous ways. It became safer to stay up all night in the emergency room. I slept during the day. I missed a lot of school. I was able to forge notes from my mom and escaped consequences of unexcused absences for almost a year. My physical and emotional state became unmanageable and my distress apparent. I cried for days. I felt so alone, trapped, and abandoned. There was no one I could tell without getting into trouble. I went to school one day and collapsed on the gym floor. I had a miscarriage. My friend Wanda recently told me that I was curled up in a ball on the floor. I was whispering to her, "Wanda, please don't let them come and get me . . . please . . . please!" She cites this as my introduction to the mental health system. All I know is that in 1966, at age 15, I had my first visit with a psychiatrist.

The psychiatrist was a woman who came from another country. She had a heavy accent. I was too shy to tell her that often I did not understand a word she was saying. I wanted to trust her. I immediately acted as if she loved and cared about me even though I did not really know. I was starved for affection and love. I was so lonely I could die. I wanted someone to trust and love so much that any semblance of trustworthiness and any inquiry into what I wanted passed for love and caring. Simple courtesy and proximity with another human being who asked me questions were soothing. These simple acts of kindness and professionalism were the salve and balm that soothed my wounds emanating from torture, abandonment, and neglect. I learned to glean hope and security from her gestures, pseudo-trust, and questions that I thought were enough for me to prove that she loved me. The professionals became surrogate family with all the attending loyalties and conflicts, and later therapeutic relationships were enough.

At age 16, I entered a public psychiatric institution and started on my path of receiving professional services in lieu of mutual loving nurturing relationships, with the goal of reducing pain and fear. I was terrified on entering Boston State Hospital, but from the first moment that adults asked me what I thought, what had hurt me, and what I needed, I was hooked on treatment. The focus was on me, and people said they wanted to help me feel better. I have stayed in mental health treatment for 39 years because I settled for the promise of caring. Professional caring was, and still is, the only caring that has felt safe enough for me to allow in my life. This is the only caring that I felt I could get.

My treatment for symptoms of mental illness has been successful in that it allowed me to go to Tufts University and learn from five graduate programs, even though I have not completed a master's degree. I have been able to work and live on the periphery of life, settling for the love of my therapist and an apartment, and substituting work and getting well for getting a life. If appearance was the test of having fully recovered, I often passed with flying colors. As for most of us with a mental illness, recovery is full of relapses and recurrences of illness. The journey of recovery is full of moratoriums and plateaus in between mountains and valleys. The journey becomes less tumultuous for most, but eruptions of symptoms can never be ruled out. Life with mental illness is precarious and a terrible predicament in which to find oneself.

Think of what I have told you about my early life: the accounts of witnessing the death of my brother before age 6, the murder and rape of my best friend, the sexual abuse and torture I experienced, and the lynching of my uncle. Some doctors find my statements unbelievable and preposterous. One doctor even chided me saying, "Now Gloria, think about what you are saying. Don't you believe that the police would have intervened?" I would laugh except I know that his thinking is caused by the fact that most people have forgotten what life was like for Black people in 1955. This lack of historical knowledge, paired with a pervasive need to "not know" the pain of racism and family dysfunction, is extremely prevalent in our society. It always feels like a personal affront when helpers replace my real-life experiences with their theories of what "really" went on. This not being believed simply because what happened to me is out of the experience of my professional friends continually causes me the most pain in my life. The questioning of the truth of my experience occurs because my professional friends believe in the severity of the impact of my trauma and because their training requires them to dissect every statement I make in an attempt to find the errors in my thinking and judgment. This sophisticated way of "nulling and voiding" my experience and replacing it with theoretical guessing is really based only on the fantasy in their heads. These interactions always leave me feeling isolated, discriminated against, and demoralized, leaving me hopeless to ever gain credibility when my life experience is diminished because it is so radically different from that of most people.

I realize that once I entered into the contract of therapy and treatment, like a binding contract with the devil—it is perpetual, and its course is certain. It is rare that anyone who enters mental health treatment will ever escape or ever lose the devastating moniker and attributes associated with the status of being a "mental patient." After years of faithful immersion in and commitment to therapeutic treatment, I find myself left feeling tricked, deceived, and abandoned. I believe these feelings are primarily the result of my feelings of being hurt by powerful administrators within the mental health system and worsened

when my brother Junior, at age 46, died unnecessarily because of the negligence of staff within a vendor agency of the mental health system.

My interface with medical health providers has added an additional burden to my recovery. I am older and require medical care from doctors who stigmatize and humiliate me because I have been diagnosed as "mentally ill," then react with anger, hostility, and retribution to my complaints about their hurtful behavior. My other professional helpers have not responded to my pleas to help me access basic rights to humane and decent treatment in medical settings. All these factors culminate in leaving me with profound feelings of despair. I missed out on structuring a life that supports and sustains me after the nine-to-five professional friends go home. My previous therapists all said that my past traumas were too devastating for me ever to marry. Therapy and the psychiatric hospitals have created a cocoon that kept me in isolation, with a fear of living. The stigma of being an older mental patient now fills me with sadness.

My lot in America meant that my life was going to be difficult. The additional burden of abuse, 39 years of mental health treatment, and an active, curious, and generally very fine mind left me disillusioned. With the awareness of what could have been, my losses test my resilience, hope, and faith. I now exist without my many disguises, my alternate selves, and without the benefit of a loving support system. This life of having to make lemonade out of lemons created habitual responses of resilience that now keep me on the planet, however unhappy and striving for better. My personal existential crisis is how do I endure, do no harm, and wait—after all I have been through? I still have hope in the goodness of people.

At Boston University Center for Psychiatric Rehabilitation Center, I met people who happened to be professionals. They were outrageously radical professionals. Their theories of how to help were not based on seeking out what is wrong with me. They did not think that it was impossible that I was their equal. They did not label me defective or tell me how was sick I was. They spoke of my having options and a valued role in life. They told me that my inability to succeed was caused by barriers. They had requirements and expectations. They made plans based on my needs, wants, and preferences, requiring me to make choices. They believed that I would achieve and grow. They inspired me and sided with my resilience, leaving me feeling energized, ready to act in my own behalf, and hopeful for a better outcome. Dr. Spaniol mentored me and gave me a valued role facilitating recovery groups and cofacilitating statewide workshops. He provided knowledge and

skills to increase my competence, and pairing this with doable expectations, he increased my overall life functioning and satisfaction exponentially. I now have a newly found identity of educator. This was a dream of mine when as a little girl, I played school with my childhood friends. These experiences allowed me a glimpse into the land of being accepted and well respected. And now, I am forever changed, and giving up is simply harder because of them. Their use of the universal concept that difficulties are caused by barriers took me out of the land of a defective human being failing to function and placed me squarely back in the land of human beings striving to overcome environmental obstacles without judgments about my intellect, character, or motivation. I was on an equal playing field with all others. I was a person who needed help, knowledge, skills, and support. I am not an inferior being treated by superiors. Many of the conflicts and power struggles embedded in traditional therapy are no longer an issue. This subtle and exquisite shift in perspective allows practitioners to have a better chance of greeting a real live person rather than a collection of symptoms.

I am an equal partner with responsibilities to participate to ensure a good outcome. As a partner with the practitioner, I do not sit passively by, awaiting my rescue. The knowledge that my counselors at Boston University cared created a feeling in me that their theories about me, their interventions, and the specific treatment outcomes were never as healing as their personhood, their stated desire and intention. Without their genuine curiosity that allowed them to listen, their respect that kept them from judging, and the high regard for my individualism that allowed them to tolerate me being me, I could not have withstood facing my woundedness and despair. The words "I don't always know how to help but I really want to help you" feel like balm on an open sore and soothe me in ways that I can only approximate by saying, "It healed my soul." This is one of the many supreme gifts of human connection that I have found only in my relationship with my therapist and my counselors at Boston University.

I have had a lot of experiences that showed me how to "make meaning" and transform injury and devastation into hopeful scenarios. Routinely affirming hopefulness and habitually responding to devastation with resilience are skills that helped me to transform evil and rise from the ashes. "The phoenix rising" is my life metaphor. As life plunges me into the depths of despair, I look inside and find a light of hope to try and live well. I have repeatedly risen from the ashes, and with my faith intact, I can envision no other response.

The Privilege of Giving Care

14

DONALD M. MURRAY

"**I** don't know who he is, but every morning and afternoon, a man comes to see me and he is awfully nice." The woman who said those words was Minnie Mae, my wife of 54 years, and I have lived by those words in the months ever since she broke through her dementia on a Friday afternoon and told the hospice nurse, "No more water. No food. No pills."

Fourteen years earlier, when she was 72, she was given her annual physical. There seemed to be none of the surprises during this exam that had tested Minnie Mae's courage, sense of humor, and ability to survive pain in the past. The doctor's calm and professional "hum's, uh-huh's, mmm's" during the exam reassured us. The doctor studied the lab reports—another comforting "mmm"—and, smiling, our doctor went to the examining room door, turned and told my wife, "You have Parkinson's," stepped out into the corridor, and shut the door behind him.

This not a story of "the elderly" and the global difficulties and pleasures of old age. I have no theories. No statistics. I have not read books, studies, or journal articles on aging. This is simply an account of the final intimacy and love of one couple facing the challenge of Parkinson's, a long-lasting fatal disease for which there is no cure. Like so many of us in our eighties, Minnie Mae was an experienced patient. Before this last illness, she had suffered life-threatening toxemia with our first child, an appendix attack with three separate infections, an emergency hysterectomy, nine—I believe—eye operations, and skin and breast cancer.

We didn't really know what Parkinson's was, but we knew that it wasn't good. There seem to be two types of elderly patients: those who worry and predict and research about what might happen and those like us who simply face each "surprise" with as much acceptance, courage, and toughness as we can summon. We take life a step at a time. Now we had a new challenge: Parkinson's.

We drove immediately to my cardiologist, who referred us to a neurologist. That didn't help as much as we hoped. We wanted to learn how to treat Parkinson's, how it might evolve, how it would affect our daily lives and our future. Instead of answers, we ran into the sort of professional terminology debate that interests doctors but not us.

Our neurologist carried on a debate with himself in front of us. Minnie Mae might have "Parkinsonism," or she might have Parkinson's itself. It was never clear what the difference was and how it might affect Minnie Mae's life. Would Parkinson's or Parkinsonism move toward death at a different speed? We were never able to understand the difference, except we were told that a blood pressure drug Minnie Mae had previously used was associated with "Parkinsonism" or "Parkinson's" in about 25% of the patient's who

were prescribed that medication. Minnie Mae (a direct person who like direct answers) asked, "What caused my Parkinsonism or Parkinson's, or whatever it is?" The doctor answered, "I'll know when I slice your brain."

Looking back, we seemed remarkably innocent and calm. The unspoken medical message was that aging is tough, but so were we (Figure 14.1).

Wet your pants?

"I have many older patients who have that problem."

Tremor getting worse?

"As you age, you'll have doctors' penmanship."

Stagger?

"That happens. My father was a minister, but when he grew old, he walked like he had two too many."

Bent neck?

"Arthritis. It comes with age."

The neurologist prescribed Sinemet. Minnie Mae took it at lunch and felt better within the hour. The specialist may have been a cold fish, but there was a pill for whatever she had. Our personalities, our genes, and our personal experience with death and illness had taught us not to seek problems. Trouble would come in its time, and we would face it head on. I think this pragmatic stoicism is typical of our Depression and World War II generation, but I also believe that many of my generation develop a passive fatalism together with the belief that the more challenges they face and survive, the stronger they become. There may be something to this. We were stoics, steeling ourselves to confront medical problems and do what was necessary to deal with them. We were not happy with our neurologist's personality, but the pills worked. He must know something even if he didn't know how to relate to his patients. Then he planned, since Minnie Mae was doing so well, to prescribe a new, more powerful drug.

At that moment, we experienced a fortunate coincidence. I was invited to speak at Beth Israel Hospital in Boston because of my *Boston Globe* column on aging. After I spoke, a reader talked to me about the column and mentioned that she was a neurologist. I asked what doctor she would recommend to a member of her family with Parkinson's, and she referred us to a kind doctor who has been called the best neurologist in Boston. He was a listener and an explainer who told us they had tested the new drug our neurologist planned to give Minnie Mae and that it would have irrevocably damaged her brain. We remained his patient until Minnie Mae could no longer make the trip from New Hampshire to Beth Israel.

When we asked him about the future—we prided ourselves on being realists—he explained that each case was so different that there was no way to predict the future. Furthermore, he told us that there was only "treatment." We did not shy away from his diagnosis, ask God why me, search the Internet for miracles, or join one of the therapy groups that help so many. We just did what had to be done hour by hour. I learned new skills, knowing that new demands would be made on those skills in the years ahead.

We learned that the most efficient way to help Minnie Mae up after a fall was to have me plant my size 15 feet on hers to keep her feet from skidding away, then, taking her hands in mine, lift trying to keep the pressure on each equal. Sometimes it took many attempts to get Minnie Mae on her feet. She used her favorite curse, "Shit fire and save matches," and many times we sat on the floor laughing at our clumsy failures. And when we couldn't get her up, we called for help from a young neighbor.

We survived by our own black humor. "You used to struggle getting my bra off, now you have trouble getting it on." We continued to go out to eat as long as it was possible. We liked The Olive Garden with its sliding chairs. One day, driving to the restaurant, Minnie Mae said, "We should bring a bottle of wine." As she traveled further and further into the confusion of dementia, she kept her humor and I kept mine. She was never a "patient" but the woman I loved.

As the disease inevitably grew worse, we realized that our geography had changed. We avoided stairs without railings, sloping sidewalks, uneven surfaces of grass and sand, and wind that could push Minnie Mae sideways. I still tell people I am with to watch the curb.

The days passed, as a poet said, like a giant water wheel that tumbled slowly, one bucket after another. I never questioned my obligation, and it did not feel like duty. It was another stage in our lives. The most difficult tasks—bladder and bowel accidents, tumbles, falls, getting Minnie Mae to take her pills—became further intimacies in our long life together.

I tried to keep Minnie Mae's life as normal as possible. A friend of mine with good intentions took over all the cooking, shopping, and cleaning. He was caring—too caring. Minnie Mae lost all purpose in her life. She was unneeded, and her mental health suffered.

FIGURE 14.1 Don and Minnie Mae Murray in their home. (Courtesy of Donald M. Murray.)

I helped Minnie Mae with the shopping, but she was in charge. For years, she scooted between the supermarket aisles at full speed with the help of a grocery cart. She had been a great cook, but her meals became ordinary or worse. She knew it, but it was important that she was still in charge of the kitchen. Eating out allowed her to see different people and the beautiful New Hampshire countryside. For a long time, Minnie Mae could still shop for groceries and attend UNH hockey games, loudly coaching from the stands far longer than I thought possible. And she would stagger across the lawn with a cane, trying to work in her beloved garden (Figure 14.2).

All the time, I continued to write my column, books, and poetry. I needed to lose myself in the exercise of my craft and its deep concentration. Novelist Bernard Malamud explained, "If it is winter in the book, spring surprises me, when I look up."

It was tragic to see Minnie Mae's world grow small, but neither of us focused on the past. We focused on what could we do now—this morning, this afternoon, this evening. My daughters and I tried to treat Minnie Mae as the acerbic woman with the biting dry humor she had always been.

Many elderly people refuse to allow help to come into their home when they need it. That is a mistake. We were fortunate in having Dot Benson, who came in two or three times a week. She continued to be our cleaning woman, but as the Parkinson's increased, so did Dot's contributions to the quality of our life. She became more friend than employee. She took over the tasks that Minnie Mae could no longer do and I did not have the time to do if I was to continue to be a publishing writer. She also was a therapist, bringing the world to Minnie Mae, whose horizon grew closer and closer. She gave each of us the physical and emotional support we needed. When a couple she was caring for passed away, my psychiatric social worker daughter said, "Grab her. Right now. Get those hours." I resisted, I now recognize, because I didn't want to admit that Minnie Mae was in the early stages of dying. We needed Dot, and I am grateful for my daughter's command.

As Minnie Mae needed more and more care, a daughter, with the best of intentions, hired a team of additional caretakers. That didn't work. They didn't arrive on time or arrived ahead of time, they brought food we didn't need or like, they asked for advances on their pay that they didn't return, and worst of all, they talked to Minnie Mae in baby talk. Dot Benson was just the opposite in every way, and we increased her hours when they became available and then placed her on salary. I was 80 years old when Minnie Mae died. Dot stayed on to help me by taking over my bookkeeping and by providing computer assistance. She makes an offering of good humor each time she shows up. No cheeriness, no baby talk, just a down-to-earth model in how to live a life with acceptance while making the most of each day. I can't imagine my life before and after Minnie Mae's death without her help.
FIGURE 14.2   Don and Minnie Mae Murray in their garden. (Courtesy of Donald M. Murray.)

The years of care became normal and accelerated at the same time. I was uncomfortable with the term *demands.* There were no demands, just the increasing need for closeness and sharing. In my case, the time I had in combat as a paratrooper helped. At the front, you do what needs to be done, no question, no evasion, no excuses. The compliments of friends and neighbors who said how wonderful I was embarrassed and puzzled me. I was not wonderful. I loved Minnie Mae, simple as that. We had enjoyed better, and with the death of our daughter in 1977, we had survived worse. Who else should take care of her but the man who met her when she was a substitute blind date 54 years before?

I was fortunate to be retired from the University and had the time to care for her as I continued to write at home. Caring for someone with Parkinson's and so many other chronic diseases is a matter of small tasks—delivering pills on time, changing clothes, getting to the doctor—that accumulate so slowly that you hardly notice their increase. We had to develop our own tricks for this unplanned new trade of caregiver: how we could brace our feet against each other's so I could lift her efficiently and painlessly after inevitable falls, how a gentle hand under the armpit (developed from a not so gentle hold I learned as a military policeman) could tell Minnie Mae I was there, ready to help if she needed it, how I could wake in the night and watch her blanket so I could tell if she was still breathing.

We were, of course, both patients. She had to learn to protect her feisty, aggressive approach of life. I had to tune my Type A personality to a C while caring for someone who was living in slow motion. I had to learn not to invade her territory and, for example, take over the cooking early on. It became gradually more difficult for her, but cooking was her pride. I could not take it away from her. We had to discover how to calm or sustain each other at moments of terror or despair. When humor or yet another "Law & Order" rerun didn't work, a trip to get a dish of ice cream did. Ginger ice cream was the most therapeutic. Minnie Mae refused to worry about how her more obvious handicaps might disturb people, and we ate out a lot. I should add that everyone, wait staff and fellow customers alike, offered her respect, kindness, good humor, and help when necessary.

I suffered more stress than I felt or admitted. I did what needed to be done, but when my daughters, close friends, and doctors urged me to take care of myself, I shrugged off their counsel. I had had a cardiac bypass years before, and when I felt some heart symptoms, I went to my cardiologist, who examined me and said he would see me in three months. The symptoms continued, so a few days later I arranged for Dot to be with Minnie Mae and called 911 at three in the morning. Hours after I arrived with flashing lights at the hospital, I had a new cardiologist, and the next day I had six stents placed in the arteries near my heart. There must have been more stress than I realized.

I am surprised to find I miss the caregiving, now it is over, while enjoying the freedom to browse in a bookstore or play my music at top volume. In some way I cannot yet understand, the erotic intimacy of our first years seemed to flow into the intimacy of helping Minnie Mae dress and undress. There was nothing we did not know about each other and no moment when we were not available to the other. My job was to keep Minnie Mae from feeling shame or embarrassment as her body betrayed her. It is what she would have done for me.

The grand landscape of Parkinson's was fearful. But the day-to-day tasks that became essential as we traveled this landscape became intimate and appropriate. These were not years of hope. There are pills that can slow Parkinson's, but there is no cure. We had to accept the reality, but that did not make them dark years. When Minnie Mae started to call her cane a ladder, we laughed. No bother. I didn't correct her but simply brought the cane. Now I realize that dementia had arrived a long time before we admitted it. This was not denial but simply that we kept adapting to the language as we had adjusted to our daughters' first efforts to speak, which only we could understand. I would have expected an incapacitating horror to see the brain of such a smart, quick, opinionated woman change. Of course, it was what we had both feared the most, but it wasn't like that at all.

There are many marriages within a long marriage: no children, three children, moves to new cities and states, promotions and firing, manuscript acceptance and rejection, the children leaving, retirement, and now Parkinson's. Eventually, Minnie Mae's neurologist suggested that she be examined at a psychiatric and geriatric facility at a nearby hospital. As soon as we arrived and I saw Minnie Mae with the nine other patients, I knew we had entered a new territory some time before. Minutes after the chief psychiatrist began what would be a long examination, he turned to me and said I must activate my power of attorney. It was a chilling moment. After days of tests, it was clear that she would not come home. The fear we all have of ending our days filed away in a nursing home had come true for her. They sent her to a nursing home connected with the hospital that was as bad as any I have seen. I was beside Minnie Mae the first day when she was strapped in a chair while two nurses had a fistfight in front of us. She said, "Get me out of here." I answered, "We certainly will."

Dot and I raced from one facility to another in a day and half. Obviously, we should have visited more of them early on, but our "one step at a time" policy kept us from looking too far ahead. Perhaps we were right. Parkinson's varies radically between patients, and neither the doctors nor we could predict the care she would need. Luckily, we found a small assisted living facility—32 patients maximum—seven miles from our home. Minnie Mae had said she would kill herself before she would go to a nursing home, but she moved in without complaint. She

seemed, despite the dementia, to know she needed this level of care.

When Minnie Mae was admitted to Kirkwood Corners, an outstanding assisted living facility, a nurse told me that my wife's dementia produced fascinating fantasies. She said Minnie Mae had told the nurse that she had been one of the first people to work in the Pentagon, that she had relayed messages from Secretary of War George Marshall to General Walter Bedell Smith in London, who then told General Dwight D. Eisenhower what to do. My wife added that she was a professional mezzo-soprano who had soloed in Washington, D.C., and Boston. She said she had Q Clearance, the highest possible security status. She added that she might lose that status, since she was, according to the Associated Press, the first person in the country to get people on the sidewalk to sign a petition calling for President Richard Nixon's impeachment.

I told the nurse it was all true, not the product of dementia. The staff got to know her as a woman of accomplishment and not just another patient. "I don't know why these people treat me so well," said my wife, who had promised to kill herself if she had to go to a nursing home. The staff at Kirkwood Corners treated all their patients with respect, but Minnie Mae felt she got special attention.

Understandably, many dedicated doctors, nurses, therapists, aides, and the blessed people from hospice focus on the patient. The care is intense and continual. They are patients, men and woman, who have chronic and terminal illnesses that demand care and love. The Kirkwood Corners staff realized that the patients see themselves not so much as they are but what they were: cabinetmakers, soldiers, parents and grandparents, lawyers, bakers, secretaries, corporate executives, gardeners, researchers, gamblers, teachers, salespeople.

If those who treat the elderly get to know the worlds in which they have been productive, then respect is easy, and all the treatments are given in the context of their entire lives. During my bypass surgery, I was seen as a combat paratrooper who was familiar with pain. It helped me to return, with the staff, to another life.

Minnie Mae's father had been a baker, and when she opened an imaginary bakery in the basement of Kirkwood Corners, the cook discussed recipes as if the business really existed. Staff members took care of Minnie Mae's imaginary pack of strawberry dogs. Office staff helped with flight schedules when she had to fly to London on a secret mission for the CIA. They treated her as if she has Q Clearance. Minnie Mae was obviously happier than at home. She had better care than we could provide, and she was not isolated, as she had become at home. She would watch the daily parade of staff, residents, and visitors with some understanding and a great deal of amusement.

And how did I feel visiting her twice a day? I put aside the larger picture, as I had in combat, and focused entirely on the woman I loved. She recognized me less and less, but when I held her hand, she would give a sudden, tight squeeze, and I knew that somewhere in her clotted brain was an "I love you."

What did I learn from the years of increasing caregiving? There is as much intimacy, caring, and love at the end of a lifetime together as when we first discovered each other and grew our lives together, perhaps more. An elderly couple facing a long struggle without a terminal illness needs a calm, detailed explanation of illness. They do not need evasions. They have lived a long life together and are usually tougher than they—or you—think. Truth is better, no matter how hard it is, than the imagination of the patient and gossip about the disease related by friends. What else did I learn?

◆ Don't yank. Minnie Mae was tugged and painfully hauled up from her falls by many caring passers-by. I learned to allow her to do all she could and then be nearby to help if she needed it: hand barely touching her armpit tells her that help is at hand—if SHE needs it.

◆ Share some of yourself. Minnie Mae was delighted to hear stories about children, grandchildren, and dogs.

◆ Do not correct someone with dementia, saying, "That didn't happen in Atlanta but Utica." They can't understand, and what difference does it make anyway?

Those of us who find ourselves as caregivers will discover that we have strengths and skills of which we were not aware. What I did and every other caregiver does is done not out of duty, responsibility, and obligation but, above all, love.

Suddenly one Friday afternoon, Minnie Mae's dementia lifted, and she gave the staff clear orders: "No pills. No food. No water." It is what she had wanted, documented in writing, and my daughters and I felt she had the right to die her way, in command to the end. Hospice and the Kirkwood Corner staff were experienced, loving, and professional. Minnie Mae's daughters and I were with her most of the 11 days it took her to sleep away her life. She was treated with dignity, and she suffered no pain. I was holding her hand when she gave one last quick puff of air and was gone.

AFTERWORD

On January 2, 2007 shortly after completing this chapter, Donald M. Murray died while visiting friends. He was an Emeritus Professor of English at the University of New Hampshire. He won the Pulitzer Prize for editorial writing in 1954, and wrote the weekly column "Now and Then" for the *Boston Globe,* which explored his reactions to the process of aging. He also published memoirs, novels, short stories, poetry, and textbooks on the writing process. I asked him to write this chapter because he was a well-known faculty member at the University of New Hampshire. I was acquainted with his work because I had attended several of his writing workshops and knew a
NOW AND THEN

Friends Caring and Sharing Show the Way

Donald M. Murray

For those of us who are introspective, life is a continuous exploration into the self, where we hope to find the person we are and the person we may become. Of course, the apple does not fall far from the tree, and we discover we have become a mixed breed of our parents, grandparents, uncles, and aunts. I found this discouraging. I had thought I had made my escape.

Now I accept my genes but imagine I have a tuning dial so that I can adjust their instincts and standards to the life, far different than theirs, I have constructed. This new life has been created by friends who have seen me as I have not yet been able to see myself. With Yankee respect they have mostly kept their distance, but when they have spoken, or touched a shoulder, or given a smile of encouragement, it has been important to me.

When we lost our daughter Lee at 20, it was the subtle but sturdy support of friends that got us through those first years. They saw us as strong when we felt weak. They said we had done more than enough, when we felt we had done far too little. They gave us a future when we thought there was none.

And then came the years of Minnie Mae's Parkinson's. We attended to the hour-by-hour physical demands of living, and then the dementia arrived, and again it was friends who supported and guided me. I often felt like a huge ship being nudged into port by friendly tugs.

These friends and neighbors, too many to name, were there when I began a new life alone. First they eliminated much of the alone with invitations and visits. They approved future relationships before I had imagined them. They suggested small steps of independence and supported me when I took them.

And what have I learned? To pass friendship on. To speak out, to touch, to be there when others need me.

Donald M. Murray, "Now and Then: Friends Caring and Sharing Show the Way." The Boston Globe, December 29, 2006, reprinted with permission.

number of his former students who revered his contribution to their education and careers. Over the years, I purchased several of his books on writing and his memoirs. Every Tuesday morning I looked for his column, "Now and Then," in the *Boston Globe.*

It was only after his death that I realized how many people he influenced through his teaching, mentorship, and writing. Many of the letters to the editor detailed the personal connection people felt to Don and Minnie Mae from his columns. Many of his former students are newspaper editors, writers, and teachers. He submitted his last column to the *Boston Globe* on December 29th, just a few days before his death. We have reprinted it here as it represents much of his grace and character.

—Elizabeth Crepeau

Voices Talk, Hands Write

NICK POLLARD WITH THE VOICES TALK, HANDS WRITE WRITING GROUP

BRIAN HAUGHIE

I was born in Dumfries 42 years ago. When I was a little boy I went to Carnforth School and I was happy there. My favourite lesson was maths, 'cos I learned to add things up. I made loads and loads of friends, I had lots.

I live in a flat by myself now. I like reading the *Telegraph* every night at home to find out the news and like reading adverts. I write letters about problems like how it is difficult for disabled people to use the buses and sometimes they are printed. I sit in my favourite chair to watch television and find out what's going on.

Where I live the neighbours are sometimes nice to me and some of them are not very nice to me, they call me names. They tell me to do things when I can't do them. When I've got some shopping in my hands they tell me to use the stairs when I can't. I say, I have to use the lift for my safety, to stop me from falling.

I like going to the pub to have a drink of Coke on my own and going to the cinema to see films. I like going shopping for food in Asda and Kwik Save and going to town to look at the shops (Figure 15.1). I like going ten pin bowling at Cleethorpes Bowling Alley. I win sometimes.

Life of Wearing My Suit *by* Brian Haughie*

The first time I wore a suit I was one of two Best Men at my brother Scott's wedding and the other Best Man was my twin brother Alan.

The *Telegraph* came to my brother's wedding and took pictures. My brother Scott's wedding took place on 22nd December 1990 and the picture appeared in the Telegraph on 27th December, the last day me and my brother Alan were 26 years old. I wore a tie with the suit.

The second time I wore the suit was for my Grandma's funeral on 13th June 1994 in Bolton which wasn't a nice day for my cousin Jacqueline because it was her birthday then, but I was pleased when my cousin Jacqueline put her hand on my shoulder when she saw me crying my eyes out when I came out of the church. I wore a tie with the suit.

The third time I wore the suit was when I went to one of my annual Christmas parties. The Christmas party I wore the suit for was the Christmas party I have been going to for years since I was a little boy and that

---

*From Haughie, Brian. (2005). *Stories.* Grimsby, UK: Voices Talk and Hands Write.

FIGURE 15.1 Brian Haughie. (Courtesy of N. Pollard.)

christmas party is the Spastics' Society christmas party. The christmas party was held on 10th December 1994 at Heneage Road Youth Service Centre. It was my Mum's idea for me to wear the suit for the christmas party in 1994 and because my brother Alan came to visit and Alan put the tie on me before I went to the party.

The fourth time I wore the suit was over eight years ago for my Mum's funeral. My Mum's funeral took place at Grimsby Crematorium on April 23rd 1996 which was on a Tuesday. I was once again crying at my Mum's funeral. I started crying when I saw the hoist with my Mum's coffin on it. My Mum liked the *Sound of Music*. At the funeral they played "My Favourite Things" at the beginning of the funeral and "So Long, Farewell" at the end of the funeral.

I have been to Steels Corner House Restaurant wearing the suit. I wore a tie with the suit. And finally I wore the suit again this year on 16th July when I was told to write this story about me wearing my suit. The *Telegraph* came to take a picture and the picture appeared in the paper on 29th July which is one of my Auntie's birthday. I was very surprised to find myself in the paper on one of my Auntie's birthdays.

And that's the story of me wearing the suit.

ERICKA TURNER

I live with three men, all three come to this centre at Queen's Road. We are tenants in our own home.

I like watching *Black Beauty* on the video and *Mary Poppins.* I watch *Dirty Dancing* as well. I watch these videos at weekends. I like my breakfasts on a Saturday mornings, my favourite food is shepherd's pie, potatoes and carrots.

I like watching "Neighbours," "EastEnders," "Emmerdale Farm," and "Coronation Street" on telly. My favourite programme is "Coronation Street," all my favourite stars are there.

I type on a computer at home. I like doing gardening, I like to go out at night time. I go to the pub with Keith and Paul, I drink coke and I play pool. My favourite place to go is the youth club.

Walking Talking Doll *by* Ericka Turner*

My Mam and Dad bought me a doll with long black hair. They brought it to me when I was in bed. I wasn't very well. The doll walked and talked. It said, "tell them to find me when I run off." When I went upstairs to the toilet, it ran out!

I called it Susan. I bought some clothes for her, some dresses and some trousers. I played with her on my own. When I put her back in my bedroom and went to lie down she was downstairs, my Mam said, "she's down here."

If she had batteries in she would do it, but if you didn't put batteries in she wouldn't work. She walked downstairs and out of the house.

I went and found her in the back garden on her own, pulling flowers up. I thought "what are you doing in our back garden?" She said, "I'm picking flowers." I tried to take her with me when I went out, but she wanted to stay with my Mam. "I want to stay with your Mam and your Dad, I don't want to go out," she said. I went to the shop to buy her some shoes.

I wanted to tie them on but she wouldn't let me tie them on her. I said, "if you don't want to have them on then I'll have them off you." She said, "if you want them you can have them."

My brother broke her. He pulled all her hair off because he didn't like the colour. It was nice, it wasn't dirty because I had washed it. Then my Mam told him off about it. I had to carry on playing with her with no hair. "All my hair's gone, so I'll have to buy a wig," she said. So I bought her one.

IRIS GARRITY

I am 66, 67 next birthday, and live in Cleethorpes (Figure 15.2). There is lots of shops down our street. Our house is a big one, it is a council place. Mine has three rooms, one big and two small. I live with my friend Jayne, the two of us, but we do have a little help.

---

*From *Voices Talk Hands Write.* (2004). Stoke on Trent, UK: The Federation of Worker Writers and Community Publishers.

FIGURE 15.2 Iris Garrity. (Courtesy of N. Pollard.)

I like sewing and cooking. Tuesday afternoons, we go to Fort School. I do table cloths and tapestries and do my computers and games. I go shopping to Sainsbury's and go to the market to buy some fruit. I like oranges, peaches and strawberries and cream. I like doing cooking, scones to eat but I can't eat them because I am a diabetic. I eat baked potatoes with cheese and meat pie with vegetables. I like housework, doing cleaning especially my bedroom.

What I'd Do, What I'd Really, Really Do *by* Iris Garrity*

I'd like to be Tony Blair for a week, to go and meet people and helping people as he says, and to the Houses of Parliament to talk about meetings and other things, about the war and when people get hurt and go to hospitals to get better, and to see how they are getting on. Talking about the news how they've been getting on.

Lots of people are talking about that car bomb last night and that debris, there's a good few people what died last night.

Then there's Michael Jackson, the story about him and his baby.

I would change other things, like change staffing in the hospital so there's more staff, and it's more safer.

───────────

*From Voices Talk Hands Write. (2004). Stoke on Trent, UK: The Federation of Worker Writers and Community Publishers.

The doctors there I would change. I would take the old ones out because they're not very good and put more younger male doctors and nurses in. I'd change the beds to be better and the floors better than what they are.

More cleaners and better hoovers and better dinners than what they are now.

Better receptionist at the hospitals, and the Houses of Parliament because they're not much good when you see them on the telly.

And Tony, he goes round talking to people and shaking hands to other people. I would change that because he's always showing off.

He's always showing off to other people.

He does, yes.

And better cars to what they are now.

I would take the old ones out and put the new ones in to make more cars safer than what they are now.

I would change the police and put more and better ones in because they're not much good they're never around when you want them.

And about them lollipop ladies as well, I'd change everything around. I'd make it safer because it's not very good, as they get knocked down, two of them did.

I would change the hairdressers. I'd put new ones in and old ones out because, they're alright, but not as good as they used to be and different hair styles and different kinds of hair dryers would be good.

I would change the Farnhurst staff upstairs. I'd put new ones in and olds ones out, but not Mandy Ives. I'd get rid of all the old ones from upstairs and new ones in, because they're not much good them upstairs, because I can't go up there. I can't always get up the stairs and this makes me feel that I'm not welcome.

DISCUSSION

It is often assumed that people with learning difficulties cannot really express themselves. This chapter demonstrates how occupational therapists can provide a client-centered program that enables people with learning difficulties this opportunity. Voice Talk, Hands Write was negotiated as a community arts and education initiative with social services—in other words, outside a health context. The project involved complex input from the Federation of Worker Writers and Community Publishers (or Fed) and some of its member groups: Pecket Well College (a cooperative adult and basic education facility), the Grimsby Writers group, and local support workers. It secured funding for a twelve-session writing group with a day center and other local clients with learning difficulties who chose to come. The project focused on the development of creative, expressive, and social abilities. Its principal aims were:

◆ To form a writing group for people with learning difficulties

- ◆ To produce community publications of the participants writing
- ◆ To publish the project in professional media with the participants' agreement.

What Are Community Publishing Practices?

Creative writing is often used in occupational therapy (Pollard, 2004a), but writing and community publishing involve a complex range of other occupations. The purpose and meaning of the writing activity described here are a vehicle for addressing multiple occupational goals, which are contained in the Fed's own purpose of "making writing and publishing accessible to all" (FWWCP, 2005). This international association of people who write about life in their communities includes many writers with experiences of disabling conditions. This project came about because the Fed wanted to enable more people to experience the benefits of community publishing.

A key aim of the project was to enable the group and its supporters to develop skills for sustainability. Community publishing originated in the politically radical counterculture of the 1970s, through alliances with marginalized sections of the population on the basis of inequalities of gender, race, class, or low literacy (Courtman, 2000; Mace, 1995). Because marginalized people have often not known how to approach arts funders, activities have depended on volunteer commitment and the ability to publish cheaply by learning to do it yourself. Until it decides to publish, a writing group needs only pens and paper, which people generally provide themselves. The greatest cost is the meeting space and the input of support workers. This is important in working among people with disabilities, who often have contact only with paid workers and therefore are excluded from building "real relationships within their own communities" (Mason, 2002, p. 56), an essential element to being an active community publisher.

Grimsby offered potential for these essential connections. The Fed's then chairperson worked in the Grimsby Social Services Department and proposed working with a local day center for people with learning difficulties. She convened the large and strong local writers' workshop, with people who were interested in developing new activities around writing (Figure 15.3). The Fed's magazine editor is an occupational therapist who was then working as a part-time research development worker in the mental health trust that served Grimsby.

As a consequence of its origins, community publishing is a very open activity. Two principles are that writing can include oral composition that is not necessarily transmitted to paper and that community publication includes any means of reaching an audience, including performance. Cassette tapes and, increasingly, CD-ROM formats (with both sound and text) can be cost-effective and more accessible than print (Pollard, 2003, 2004b, 2004c). This range of media combined with the participative and

FIGURE 15.3 The group works on their writing during the meetings, but many members also write at home. (Courtesy of N. Pollard.)

diverse nature of making community publishing accessible offers many extensions of the writing process and links to new occupational roles (Pollard, 2004a; Pollard, Smart & Voices Talk and Hands Write, 2005).

Not Therapy but Empowerment: Why Take Writing Seriously?

Writing is a private activity that makes truths clear only to the writer, but publishing makes these truths available to others. In mental health contexts, therapeutic writing projects have been used to assist in the promotion of community and trust (Philips, Linington & Penman, 1999), even after war, particularly among children (Simo Algado & Burgman, 2005). Some (e.g., Foster, 1988) have included a subsequent community publication (Cox & Duffin, 1988), while the mental health survivors movement (see web addresses at end of the chapter) have encouraged publications that aim at a broad audience. Those produced with and for people with learning difficulties have mostly been intended for their own local groups rather than wider communities, partly through apprehension about exposing these indi-

viduals to public prurience. Often, these publications are difficult to obtain; consequently, they remain hidden. There are exceptions: *Our Lives, Our Group* (The Thursday Club, 2002), produced by adult women with learning difficulties, was an inspiration for this project.

For community publishers, writing is a socially inclusive political act that promotes the artistic expression and exploration of feelings for the appreciation of others through writing and dissemination. The word is treated "as if it counted in the world" (Willinsky, 1990, p. 187), the writer with learning difficulties is taken at face value as a *writer* (Sampson & Hunt, 1998). The connection of community publication with therapeutic activities can be controversial and problematic. The responsibilities associated with this stance should be carefully negotiated:

◆ Collaboration on publication projects raises professional and ethical concerns about publishing "the unsifted contents of a troubled mind" (Bolton, 1999, p. 225).
◆ Publication may create an intense local prominence, which individuals are sometimes ill-equipped to deal with (Pollard 2004c). This may lead to libel action and even physical retaliation if community members feel that they have been maligned.
◆ The cathartic and therapeutic aspects of writing activities have been used to dismiss the value and content of "worker writing" (Morley & Worpole, 1982), especially when the writer has disabilities or is an adult learner.
◆ Publication of their work means publicly acknowledging a stigmatizing illness or that they are literacy learners; consequently, some people have not participated in the celebration of their publications (Fitzpatrick, 1995).

Us in Our Town *by* VTHW Group

We like to live in our community
With our friends we have real unity
We choose to live in Grimsby, Cleethorpes and about
We live in houses. From high rise flats we have to shout
We don't let vandals get us down
We can move to other parts of town
In community gardens there are flowers and trees
We can be as quiet as we please
This is why we live in our town.

Voices Talk, Hands Write are a group who directly raise local awareness of the real needs and lives of people with learning difficulties through the publication and performance of writing (Figure 15.4). Once established and with local volunteers to support them, the group then decided to continue meeting, although funding has been difficult to obtain. The group could not have been sustained without committed volunteer input. Writing is usually produced in group sessions in response to a topic that is chosen and negotiated between the members. The finished pieces are immediately read back to other members, but some members also write at home about subjects of their own choice. All the members have taken part in public performances at venues ranging from the town hall to the local pub and even local radio. In December 2005, one of the group members, Brian Haughie, was awarded a laptop computer and printer by a local charity in recognition of his achievements, while a second anthology was about to go to print. This continuity is a significant indication of the group's sustained interest, commitment, and sense of achievement.

FIGURE 15.4 Voices Talk, Hands Write Group in their local pub, the Tap and Spile, Grimsby. Writing groups are also about socializing, and Voices Talk, Hands Write often go out together, just for a change. (Courtesy of N. Pollard.)

CASE STUDY: *Mark Wainwright: A Writer with Learning Difficulties*

Mark Wainwright is a 35-year-old man with learning difficulties who lives with his parents. He has a part-time job at the local market, where he works in a greengrocer's stall. Sometimes he goes to the pub after work with the other people from the market.

Two days a week, Mark attends a day center for people with learning difficulties, where he meets his girlfriend and attends a writing group that is led by an occupational therapist. The group has given performances at the center and at residential units and has now published a collection of poems. Mark and his fellow workshop members have been told that their collection will be ready to coincide with the town's literature festival. They are so excited about having their work in print and organize a launch party. The occupational therapist is very proud of the group's achievements and can't wait to begin distributing the poetry collection, which her managers are very pleased with.

The following day the occupational therapist receives a phone call from Mark's mother. She objects to his poem about getting drunk with his mates from the market. She says that she should have had advance warning that his work would be published. Had she known, she would have stopped him participating. She asks for an apology.

1. Does the right of people with learning difficulties to write and publish compromise their carers' or relatives' right to confidentiality? How does an occupational therapist determine whether community publication is an appropriate occupational activity?

The occupational therapist takes the group and some support workers to a reading event at the library. The group members are in their best clothes and have carefully rehearsed their performances. The receptive audience give enthusiastic applause, even though some readings are difficult to understand. However, Mark becomes upset when he overhears the remark "I came to hear some literature, not a bunch of clowns from a therapy group."

2. What are the barriers for people with learning difficulties who want to participate in artistic and creative activities in the wider community and how would an occupational therapist empower individuals and groups to overcome these barriers?

Several months later, the group reviews its achievements. They recall the things they have written about and the events in which they have participated. Many of the anthologies are still unsold. They decide to have a "press conference" with the social services press officer to celebrate one year since the group started and to promote the remaining anthologies through a day center magazine. Their interview is also reported in the local paper, but they find that the articles have concentrated on the occupational therapist rather than the group. Many of the responses articulated by group members have been ignored. "They've made us look stupid," Mark says.

3. If they are community based, arts projects that involve people with disabilities can have unpredictable outcomes. How can an occupational therapist structure the experience to enable everyone to get the most benefit from participation?

Mobilizing the Collective Action of Disabled Women in Developing Contexts to Tackle Poverty and Development

THERESA LORENZO

Learning Objectives

After reading this chapter, you will be able to:

1. Share narratives of South African women with disabilities who participated in a series of narrative action reflection workshops
2. Describe a human rights approach to equalizing opportunities for disabled women, with particular focus on women who live in developing contexts
3. Illustrate the shift from individual focus in rehabilitation to a population approach in addressing disability issues

This chapter shares the human development narratives of disabled women who live in wooden shacks in the periurban areas of Khayelitsha and Greater Nyanga, in Cape Town in the Western Cape Province of South Africa. Human development is

> a process of change that enables people to take charge of their own destinies and realise their full potential. It requires building up in the people the confidence, skills, assets and freedoms necessary to achieve this goal. (Taylor, 2000, p. 49)

An important aspect of this definition of human development is the access citizens of a country have to an environment in which they are able to obtain opportunities and resources and makes choices to live decent lives. Taylor (2000) adds that human development recognizes that people need economic, social, cultural, political, and human rights in order to develop to their fullest potential and to live meaningful lives. She identified access to water, knowledge, health care, employment, and other productive resources as basic ingredients for human development. In South Africa, human development has been impaired because these rights have been denied to the majority of the people. South Africa's rate of poverty is 45%, which means that more than 18 million citizens (or 3,126,000 households) live below the poverty line, which is pegged at an income of R353 [approximately US$59] per adult per month (Taylor, 2000). In rural areas, the poverty rate rises above 50%. Besides experiencing simultaneous oppression related to race, gender, and disability, poverty creates a fourth form of oppression.

Over a period of two and a half years, many disabled women participated in narrative action reflection (NAR) workshops led by the author (an occupational therapist herself), another occupational therapist, and a disabled woman. We planned these workshops to combine action learning (Taylor, Marais & Kaplan, 1997) and storytelling (Slim and Thompson, 1993) with narrative inquiry to enable participants to describe the meaning of human actions and link them to larger social concerns (Clandinin and Connelly, 2000). We facilitated the workshops in a way that enabled the women to tell their stories and to analyze the stories to raise their awareness of the root causes of their oppression. This cycle of action and reflection occurs within a single workshop, as well as between and across workshops (Hope and Timmel, 1995). In this way, the process aims to enable each woman to feel heard in a way that mobilizes her to take action toward social change (Figure 16.1).

The women who participated in these workshops are mostly single mothers who look after more than just their own children. They are also responsible for members of their extended families. Many have migrated from the rural areas of the Eastern Cape in the hope of finding better medical care and economic opportunities to alleviate their poverty.

FIGURE 16.1   Women in workshops learn to listen to each other's stories with Marjorie as facilitator.

BULELWA: I SEE MYSELF AS A LIGHT FOR OTHER DISABLED PEOPLE

Bulelwa is a vibrant entrepreneur, very hard-working while being very concerned for the well-being and growth of the other women in the workshops. She shares her story:

> After the first workshop where I told my story, I felt much stronger. I realized these workshops could really help other women in the same situation as me. Our rehabilitation did not help us return and settle back with

our families or communities. Here I made a clay sculpture of a plate and two women to share how I changed from gaining knowledge of disability rights and advocacy skills. The workshops helped us to find knowledge and information for each other. We felt happier. We recognized the gains we've made in changing our living conditions. These skills have led to a better life together. I made myself using clay. I want to show you that before I became disabled, my body was thin. I was small before and you can now see how big I am. So I want to share the good news so that others can be big like me. I must be the light, even in the community and preach about disability and how they can treat disabled people. I talk about disability. I became more confident and gained skills in being able to change things. I was used to speaking in church and sharing my testimony. Now I speak about disability. I also loved to sing and dance.

I see myself as a light for other disabled people and I'm not afraid. I know I'm able to talk. I'm usually shy, but since I've been here I am free. I used to worry a lot at home, but since I've been here I'm much better. When I see my neighbours quarrelling, I say to them "Call your family and sort this out." Later they say to me "Really we called them and we solved it." So that is why I'm saying I'm a lamp. I see that even with the women, there is change. I'm able to see how they were before and how they are now. Ever since they have been meeting in the groups, the load was taken away and everything has been lighter.

So I was not the only one who wanted to shine a light to change attitudes to disability ourselves, amongst our families and our neighbours. The workshops also helped us see how we could heal each other. The workshops gave us courage to be visible in our families and community again. I told a story from the Bible: "I identify myself with the person who was next to the dam and people were coming and going not helping him. So Jesus asked him, 'do you want to be well?' 'I want to, but I don't have a person who will help me and put me in this dam.' Jesus said 'take your mat and go and by those words you are healed.' " So now I'm well, but it's sad when you see others having problems.

THANDISWA: NOW I FEEL I CAN DO ANYTHING

After her discharge from a general hospital where she received physical rehabilitation following a stroke, Thandiswa stayed at home and felt quite isolated from her community. She told the group how much her participation in the workshops had helped her at personal, family, and community levels:

I experienced deep changes about how I feel. I used to cry a lot, but since I met other women, I got new ideas.

I joined the Nobantu group.[1] When Bulelwa introduced me to the group, I was happy and I became one of them. I understand more about this impairment now. When I became disabled, I always undermined myself when I was with my friends. I always sat in one place. But when I met with the other women I became stronger and that thing of always feeling sorry for myself is gone. My in-laws did not love me but today my house is always full. I'm strong. Today I'm not crying. Now no one can believe that I used crutches before. No one can say I'm disabled now. I identify myself with the sun because before it was dark and I didn't want to accept my disability. I couldn't even sit in the sun. Now I can do things with my hands and I got a certificate in business skills. After that I could do things for myself. Now I'm like a mother in the house even when the children are not there. I never used to be like that. I used to wait for them to come back from school. Now I feel that I can do anything.

GLORIA: THEY SEE A MOTHER WHO IS A ROLE MODEL

Gloria had been disabled by polio as a child. She told how her children had found support from the workshops as well as they also felt the pressure to change the stigma of disability. Gloria said:

I'm receiving a lot of support from my family. My two children always show interest in what I'm doing. At school they used to be laughed at by other children because of my disability. But they told them that with their mother, they can't see any disability, but they see a mother who is a role model and who can afford everything unlike nondisabled mothers who can't afford the basics. You see nondisabled mothers who can't even afford buying their children shoes. As mothers we learnt to teach our children respect and good social skills. Your child has a right to ask for things from you, but you need to teach them to talk nicely when they are asking for something. They mustn't go and ask for something from other people because they think you can't do things since you are disabled.

NONTSIDISO: A PILLAR OF STRENGTH

Nontsidiso had a tubercular spinal deformity as a child, leaving her with a hunchback. However, it was not her impairment that made her feel different from other children, but rather the poverty and the loneliness she expe-

---

[1]A small business group that was initiated in Khayelitsha in 1996 that started with some of the disabled men with the support of the community rehabilitation workers.

rienced after the death of her parents as a young child. Nontsidiso was unable to complete her schooling because of poverty. As an adult and single parent, she also faced the absence of spousal support. Her abbreviated story follows.

> I am Nontsidiso. I am *intsika,* a pillar of strength, because now there is nothing that I cannot do. I cried a lot when I told my story in the beginning, as I had never shared my story with other women before. I didn't feel I was different from other children when I grew up with a hunchback. We lived in the Transkei.[2] I came to Cape Town with my mother because she was sick. My mother died leaving me alone with her youngest child. Now I felt lonely and powerless because I had no mother, no father, not even an older brother who could help me. I don't have a sister. I had no money and used to ask for food from the neighbours. Now I saw that I was not like other children. Other children were not hungry; I was hungry. I dropped out of school because of money problems. Then I had two children of my own, but their father didn't help me. He is a drunkard and drug addict and he beats me. I called the police one day and they beat him. I have also reported my problem of being beaten in the community, but no one does anything. I was suffering and my children were suffering. Sometimes, friends and neighbours help me with food. I couldn't get a disability grant. Then I heard from the social worker about the women's group. I came because I wanted advice to help my children.
>
> I was also in the group that went to the catering workshops as part of skills development in business (Figure 16.2). I didn't know that so much would come up with so little popcorn. I got a certificate now so that I can get a job in catering and do something with my hands. I didn't know that I could be taught and become educated. I see how I was able to change inside from believing that I could not manage to work. Now I am able to make mats that I learnt about at Philani Nutrition Centre.[3] I work on my own. Another man has promised to take me to a place to get material. Even with the beads, I don't ask anyone. I make them on my own.
>
> My confidence increased, so did my hope and belief that the feelings and beliefs of my family and neighbours towards me would change. I wanted to change being called names. Even if I'm walking, people say "shame, that cripple." I wanted to change the way they say when I'm talking "Don't listen to her, she's handicapped." I wanted to be seen on TV or to take a flight and then my family would say, "oh her, we were looking down on her." The opportunity came for me to go with Marjorie to the national Disabled People South Africa (DPSA)

FIGURE 16.2   Women participate in catering workshops to develop skills in entrepreneurship.

> Women Achiever Award ceremony. The group was excited with me, clapping and rejoicing. Now it was my first time to go to Johannesburg. I was really excited about taking a flight. Now I'm not scared of disability. I'll be someone one day. My family began to see me participating in national DPSA conferences. Before I could not go to occasions in the community because I was shy. Now I'm used to sharing with people from different areas. I forgot totally that I don't have parents. I really appreciate what I get from other people. So if people are laughing at me now, I don't cry, so up with Marjorie.
>
> As disabled women, we didn't know what to do after being disabled. The job of women in the community is to make the traditional African beer that is drunk by the men at special ceremonies. We were very excited when one of the women made a clay sculpture of the pot from which the men drink different African brews. The pot reminded other women of what they could do. When we sat down and thought about our future, we realized we could make *mqombothi* [African beer] and sell it. We realized that in this group we would succeed. We could make *marewu* [sour milk] in this calabash whilst we're still alive so that we can succeed. So this pot (group) gave us life and a name in our community.'

SELF-DEVELOPMENT, CREATIVITY, AND ADVOCACY

The women found that the workshops were a good space where they felt nurtured. One woman made a clay sculpture of a tree to symbolize the potential among them. The tree's roots represented the women growing as different people from different areas. They made friends as they have been together in the workshops. The passion and energy for advocacy and spreading the message revealed an evangelical zeal. The women grew in confidence to speak about disability to other disabled and nondisabled women as well

---

[2]A rural area in the Eastern Cape.
[3]An NGO in Khayelitsha that provide nutrition programs for children and skills development in income generation for mothers and women.

as the wider community organizations (Figure 16.3). It inspired their self-development. They mobilized each other to rethink their images of disability and challenge public stereotypes. They acted collectively to raise awareness and advocate for change in attitudes towards disability.

These stories portray some of the tensions of personal and social change, which disabled women have to negotiate in pursuit of freedom, inclusion, and equal participation. Disability and innate potential, realism and anticipation, fact and faith, permanence and transience are juxtaposed throughout a poem, "Waiting to Succeed," which was composed from the women's responses to a question, "What are you waiting for?" that was posed by the facilitators. The poem is an edited extract from a published correction of their stories about living with a disability in Khayelitsha (Lorenzo et al., 2002).

Waiting to Succeed

I am waiting for success in my life,
whereby God will give me power to succeed in my struggles
so that one day I can help other people who are struggling
and teach them that they must take what they have,
even if it's small,
and know that success lies within themselves.
I am waiting for success in my heart;
As a disabled person, even if I'm sitting,
I have hope inside.
I am waiting for success in my problems;
Since I became disabled, things are slow,
now I must first think
about how I'm going to get something,
then wait until I get it . . .
I am waiting for God
to give me freedom
to get a job, to get money
so that I can buy small things to sell . . .
so that I can have a perm
and be beautiful more than this.
I am waiting for happiness,
for hope that God will add more years to my life . . .
I am waiting to be helped with my disability,
for a walking stick to help me walk,
because my legs are too lame to walk on my own . . .
Some hardships in this world come and go.
I am waiting for Jesus to come and free me
from my ties and problems.
The devil is waiting for big things from me
but he will never get them
because I don't belong to him.
I pray and worship the One above who helps me.
I am waiting to succeed
in all that I wish and hope and pray for.
And I will see the results of all these things
in my disability and in my children.[4]

---

[4]"Waiting to Succeed," from a creative activity with women in a NAR workshop. The poem is an edited extract from a published collection of their stories about living with a disability in Khayelitsha (Lorenzo et al., 2002).

FIGURE 16.3   Disabled women and men are trained in drama for disability awareness and advocacy by the Community Arts Project.

FIGURE 16.4   Disabled women participate in a skills development workshop to demonstrate sewing and machine knitting skills as a means for small business development.

REFLECTIVE SUMMARY

The workshops created a space for the women to make their voices heard. Their stories reveal that disability is a human rights issue in the struggle of disabled people for opportunities to participate as equal citizens of their community and country. The complexity and multidimensional nature of poverty require a collective approach of individuals, families, communities, organizations, and institutions to sustain change initiatives. The stories in this chapter show that it is feasible for occupational therapists, as professionals and academics, to engage with disabled people in partnerships for research and development that leads to social action and change.

Fifteen women who had participated regularly in the monthly NAR workshops published their stories about the changes that happened in a book titled *On the Road of Hope: Stories of Disabled Women in Khayelitsha* (Lorenzo, Saunders, January, & Mdlokolo, 2002).[5] The women were excited and proud when they received copies of the book, which raised their morale and self-esteem. Profits from the book go back into the Disabled Women's Development Project of DPSA for other development initiatives.

This chapter suggests that there is not much about these stories that would distinguish these women from other nondisabled women. Such evidence supports the fact that their impairments do not make the women unable to learn and achieve. The potential for responding to rebuilding the social fabric of our communities would be applicable to any other disadvantaged groups as well. The power of the collective to foster change through engagement in occupations at individual and societal levels was evident, as it facilitates an inward journey that leads to outward actions. The spirituality of the women reinforced their resilience to address the obstacles they encountered. Occupational therapists should move from the comfortable zone of individual rehabilitation to embrace the sociopolitical and economic challenges that face many of the people with whom we work. Such shifts to a population approach will foster optimal human development and engagement in occupations that will contribute to the promotion of healthy lifestyles and an inclusive, just society.

III

OCCUPATION AND HEALTH IN SOCIETY

"Occupational therapy is a profession concerned with promoting health and well being through occupation. The primary goal of occupational therapy is to enable people to participate in the activities of everyday life. Occupational therapists achieve this outcome by enabling people to do things that will enhance their ability to participate or by modifying the environment to better support participation."

World Federation of Occupational Therapy

Social and Health Policies in the United States

JAN NISBET

Learning Objectives

After reading this chapter, you will be able to:

1. Understand social and health policies and the major U.S. agencies responsible for people with health conditions and/or disabilities and their families.
2. Understand the role of advocacy in the development of public policies and associated regulatory processes.
3. Distinguish between general health care and long-term care.
4. Understand public entitlement programs and how they affect the lives of people with health conditions and/or disabilities and their families.
5. Articulate legislative initiatives that created programs and services for people with health conditions and/or disabilities and their families.

PUBLIC POLICY

Put simply, "public policy is anything a government chooses to do or not to do" (Dye, 1972, p. 2.) The public or social policy decisions take form in laws, regulations, funding decisions, and other actions that serve to communicate to the citizens or constituents. Public policymaking requires choices about the role of government in the lives of people and the responsibility engendered by citizens, states, and/or the federal government. The policies reflect attitudes, opinions, interests, and ideologies (Howlett & Ramesh, 2003). Theories suggest that policymakers as well as citizens are guided by self-interest and make choices according to "best advantage." For example, the Americans with Disabilities Act (1990) was passed after people with disabilities organized to gained access to public and private facilities and services. Many businesses opposed the ADA because they feared that ensuring access and providing accommodations was too costly. Policymakers made a decision to support the law with caveats such as "to the maximum extent possible," thereby appeasing businesses and individuals with disabilities and assuring constituent satisfaction. Clearly, private

and public organizations and groups influence public policies, but they do not enact laws. Elected officials in the legislature have that responsibility. However, understanding how to influence public policy is critical. Equally important is understanding the nature of influence and the role that organized groups with organized resources can have.

Silverstein (2000) identified five categories of laws affecting people with disabilities:

◆ Civil rights statutes (e.g., ADA, Fair Housing Act of 1968)
◆ Entitlement programs (e.g., Medicaid, vocational rehabilitation)
◆ Discretionary grant programs (e.g., Individuals with Disabilities Education Act, Centers for Independent Living)
◆ Regulatory statutes (e.g., Voter Registration Act of 1973, Family Leave Act)
◆ Miscellaneous provisions (e.g., Targeted Jobs Credit, Disabled Access Tax Credit).

He also summarized the core underlying principles that provide the framework for disability policy in the United States. These include (1) equality of opportunity; (2) full participation, empowering individuals and families; (3) independent living; and (4) economic self-sufficiency. These core principles have been articulated by advocates and legislators in many legislative actions and efforts, and they continue to be reframed and reemphasized in emerging policy initiatives.

ADVOCATING FOR CHANGE

Numerous advocates of community organizing to influence public policy (Alinsky, 1989; Biklen, 1982) make clear the role of powerful corporations and interests in the development of policies and practices that are not congruent with community welfare. Our inability, as a nation, to move toward universal health care can be blamed in part on powerful private markets, including health insurance, private medicine, and pharmaceutical companies (Johnson & Broder, 1996). Advocacy groups, such as ADAPT, represent individuals with disabilities who want affordable and accessible transportation and the removal of the **institutional bias** in the Medicaid program. Institutional bias refers to the fact that dollars can be expended on institutional care, nursing home care, or other segregated settings but cannot be expended in community-based settings. Advocacy groups have used effective strategies that require organized efforts to confront powerful interest groups. Each year, members of ADAPT protest at the annual meeting of the American Hospital Association, another group that has opposed removing the institutional bias in the Medicaid program. Federal legislation designed to support and more fully fund community-based services has been opposed by the powerful nursing

home industry and, as a result, has not been passed and implemented. ADAPT is an example of one kind of advocacy group. Others exist to represent the interests of organizations such as community health care clinics, and service providers (e.g., American Occupational Therapy Association) as well as specific populations, such as children, retirees, people with Alzheimer's, and people with amyotrophic lateral sclerosis, multiple sclerosis, Down syndrome, autism, and others.

Organized protests are one form of advocacy. Christopher Kush (2004) in his book *The One-Hour Activist* recommends 20 strategies that anyone can use to influence policies:

1. Learn how grassroots advocacy works.
2. Pick your issues and your angle.
3. Identify and meet with your senators and representatives.
4. Join an interest group.
5. Create a legislative agenda.
6. Analyze a bill.
7. Conduct opposition research.
8. Write an effective letter.
9. Send a powerful e-mail.
10. Make a compelling phone call.
11. Persuade others to act.
12. Get out the vote.
13. Contribute money to candidates who support your cause.
14. Start a press clippings file.
15. Write a letter to the editor.
16. Have a face-to-face meeting with your representative.
17. Testify at a public hearing.
18. Participate in a protest.
19. Volunteer for a political campaign.
20. Pitch a news story or give an interview (p. viii).

Each of these strategies, alone or combined, can move a public policy agenda forward. Although individuals can make a difference acting alone, organized groups have proved more effective in influencing the outcomes of elections and public policy reforms.

PUBLIC HEALTH: THE FEDERAL ROLE

The World Health Organization (1946) defines health as a state of complete physical, mental, and social well-being, not merely the absence of disease or infirmity. Public health emphasizes population-based interventions and measures as well as prevention of both primary and secondary conditions and disabilities. Public health can be viewed broadly and interpreted to encompass prevention, both acute and long-term care, and overall community infrastructure and is focused on the health of the population rather than on that of any specific individual. According to the Institute of

Medicine (1988, 2002), the mission of public health is defined as "fulfilling society's interest in assuring conditions in which people can be healthy." Gordon (1997) defines *pubic health* as the art and science of preventing disease and injury and promoting health and efficiency through organized community effort. In contrast, *health care* involves the diagnosis, treatment, or rehabilitation of a patient who is under care, accomplished on a one-to-one basis (as cited in Patel & Rushefsky, 2005, p. xii) Only 2–3% of all health care expenditures in the United States are directed at public health (McFarlane, 2005). The vast majority of dollars are spent on curative health rather than preventive health (Patel & Rushefsky, 2005). Despite this disparity in funding, Americans' life expectancy has increased by 30 years in the last century. Twenty-five of these years are attributable to public health campaigns to increase seatbelt use and to reduce coronary artery disease, more family planning, improved oral health, fluoridation of drinking water, decline in smoking, better sanitation, improved safety in the workplace, vaccines, and improved pregnancy practices (Patel & Rushefsky, 2005).

Medicaid, for example, is a federal and state program that many people consider to be a public health program and that is targeted to people who have lower incomes and those with disabilities. Yet one could argue that it focuses primarily on health care but funds many things that are considered to be in the realm of public health, such as screening and vaccinations. It supports parents, children, seniors, and people with disabilities. Administered by the **Centers for Medicaid and Medicare Services (CMS)** in the U.S. Department of Health and Human Services, Medicaid provides a useful lens through which to understand public health and health care policies involving people who are poor, are elderly, and/or have disabilities. Medicare, the federally funded insurance program for individuals over the age of 65 years and for younger individuals with specific disabilities, is also considered a public health program by some yet funds primarily treatment-related activities. Because there are so many definitions of public health, it is sometimes difficult to describe exactly what it is and why it needs to be supported (Patel & Rushefsky, 2005).

The **Centers for Disease Control (CDC)** "is the principal agency in the United States government for protecting the health and safety of all Americans and for providing essential human services, especially for those people who are least able to help themselves" (CDC, 2006). Founded in 1948 to help the United States combat the threat of malaria, the CDC today has far-reaching goals (see Box 17.1). The CDC addresses these goals through public awareness, dissemination of evidence-based practices, research, and working with other public and private entities to advance prevention and wellness (Lang, Moore, Harris, & Anderson, 2005). It makes the public aware of "threats" to their health such as tobacco use, overconsumption of alcohol, risky sexual behavior, poor

nutrition, inactivity, obesity, and environmental toxins. The CDC also serves as an important source to inform and alert policymakers about impending public health threats. For example, the CDC has focused on improving the health infrastructure necessary to respond to the avian flu virus, bioterrorism, and natural disasters such as hurricanes.

The **Health Resources and Services Administration (HRSA)** in the U.S. Department of Health and Human Services is the primary federal agency for improving access to health care services for people who are uninsured, isolated or medically vulnerable (HRSA, 2007). It has seven goals (see Box 17.2). It accomplishes these goals by funding numerous programs such as community health centers, the national health service corps, training for diversity and disparities in health care, public health workforce development, nursing programs, the maternal and child health block grant, programs for people with traumatic brain injuries, Healthy Start, universal newborn hearing screening, genetic services, and emergency services for children's rural health programs. The HRSA works closely with other agencies such as the CDC, the Food and Drug Administration, the Environmental Protection Agency, the Indian Health Service, the Occupational Safety and Health Administration, and the National Institutes of Health to advance its goals.

BOX 17.1

CDC GOALS

1. Healthy people at every stage of life
2. Healthy people in healthy places
3. People prepared for emerging health threats
4. Healthy people in a healthy world

BOX 17.2

HRSA GOALS

1. Improve access to health care.
2. Improve health outcomes.
3. Improve the quality of health care.
4. Eliminate health disparities.
5. Improve the public health and health care systems.
6. Enhance the ability of the health care system to respond to public health emergencies.
7. Achieve excellence in management practices.

PUBLIC HEALTH INITIATIVES

There are numerous public health initiatives and programs, many of them underfunded. For example, in 1988, the Institute on Medicine (IOM), which has as a mission "to serve as an unbiased and objective advisor to the nation to improve health," undertook a study of our nation's public health system. Many members believed that the U.S. system was in disarray and that the United States was ignoring such issues as HIV-AIDS, exposure to toxic chemicals, the aging of America, chronic illness, and disability. The IOM reported that millions of Americans (over 25%) do not have a regular source of health care or have difficulty obtaining it. The Kaiser Commission on Medicaid and the Uninsured (2006) reported that 17% of people with moderate incomes, 36% of the poor, and 30% of the near-poor were uninsured in 2003, an increase of 1.4 million from 2002. This amounts to a total of 44.7 million non-elderly (under age 65 years) who are uninsured in the United States. The uninsured have poorer health outcomes, more unnecessary hospitalizations, and higher rates of emergency room utilization; get diagnosed later with significant illnesses; and have higher mortality rates than those with insurance. (Bodenheimer & Grumbach, 2002).

The IOM followed up on the earlier study conducted in 1988 and made a number of recommendations regarding the public health system that address the multiple factors that affect the population. Each of these recommendations has implications for public policy refinement and development (Institute of Medicine, 2002, p. 4):

1. Adopting a population health approach that considers the multiple determinants of health
2. Strengthening the governmental public health infrastructure, which forms the backbone of the public health system
3. Building a new generation of intersectoral partnerships that also draw on the perspectives and resources of diverse communities and actively engage them in health action
4. Developing systems of accountability to ensure the quality and availability of public health services
5. Making evidence the foundation of decision making and the measure of success
6. Enhancing and facilitating communication within the public health system (e.g., among all levels of the governmental public health infrastructure and between public health professionals and community members)

THE HEALTH CARE WORKFORCE

Clearly, one of the factors necessary to improve public health is the workforce. Unlike clinical health workers, public health professionals are educated specifically to have a population versus a patient or individualized focus. Gebbie, Rosenstock, and Herandez (2003) report that these professionals are taught by using an ecological model of health that emphasizes the interaction among multiple determinants of health and emphasizes the core disciplines of biostatistics, epidemiology, environmental health, health services administration, and social and behavioral science. New disciplines are emerging and are increasingly part of public health curricula. Areas such as informatics, genomics, communication, cultural competence, community-based participatory research, policy and law, global health, and ethics are considered essential tools to track population trends, identify population and regionally specific health issues, and understand the impact of new technologies on health outcomes. Schools and programs in public health are and will have to continue to adapt to the global forces and emergent threats and issues such as avian flu, drug resistant tuberculosis, AIDS, and environmentally induced illnesses. Public policymakers, primarily through the HRSA, have targeted public dollars for the purposes of training health professionals. These policy responses, however, have not met the need expressed by both the IOM and the American Public Health Association.

PUBLIC HEALTH PRIORITIES

The **Office of the Surgeon General** (2006) has identified seven public health priorities (see Box 17.3). Each of these priorities will require policies, regulations, and funding by the U.S. government, state governments, and, increasingly, private foundations such as the Robert Wood Johnson Foundation, the Kaiser Family Foundation, and the numerous health conversion foundations that resulted from the sale of not-for-profit entities such as Blue Cross/Blue Shield and/or hospitals to for-profit entities.

INVOLVEMENT OF THE PRIVATE SECTOR

Access to employment-based health insurance has decreased over the past 10 years. The U.S. economy has transitioned to a lower-wage, increasingly part-time, and nonunionized workforce. As a result, there are increasing numbers of Americans without health insurance. Yet the United States relies heavily on the private sector to fund and support health care. Our pluralistic health care system is the result of numerous policy decisions without a comprehensive restructuring of the system composed of public health, private providers including physicians and hospitals, and the public and private insurance markets. Rosenbaum (2003) argues that our public health is threatened by the overreliance on the private insurance market. Medicare Part D, the prescription drug benefit program

<div style="border: 2px solid navy;">

BOX 17.3

PRIORITIES OF THE OFFICE OF THE SURGEON GENERAL

1. Disease prevention (HIV-AIDS, tobacco use, birth defects, preventing injury, obesity, and increasing physical activity)
2. Eliminating health disparities (eliminating the greater burden of death and disease from breast cancer, prostate cancer, cervical cancer, cardiovascular disease, diabetes, and other illnesses in minority communities)
3. Public health preparedness (terrorism, emerging infections, natural disasters, mental health, and resilience)
4. Improving health literacy (the ability of an individual to access, understand, and use health-related information and services to make appropriate health decisions)
5. Organ donation
6. Encouraging children and adolescents to make healthy choices
7. Bone health and osteoporosis (10 million Americans over the age of 50 years have osteoporosis, the most common bone disease, while another 34 million are at risk for developing osteoporosis, and each year, roughly 1.5 million people suffer a bone fracture related to osteoporosis)

</div>

for individuals over the age of 65 years, is an example of a public policy that relies on private markets—in this case, the pharmaceutical industry to provide health care. Health maintenance organizations (HMOs) have attempted to reduce health care costs by focusing on prevention and managing care. Bodenheimer and Grumbach (2002) argue that HMOs currently see themselves as responsible for individual enrollees but should also have the responsibility for offering comprehensive preventive health care to the entire enrolled population.

CASE STUDY: *Living with Amyotrophic Lateral Sclerosis*

This case study is designed to illustrate the variety of public health issues and public policies that a person and his or her family can confront during an illness or the onset of a disability.

Toby is a 57-year-old man who was recently diagnosed with amyotrophic lateral sclerosis (ALS). Before his diagnosis, he was working as a restaurant manager without health care benefits. He is able to work but fatigues easily. His physicians say that the course of his illness is unpredictable and that he might need to be in a wheelchair by the end of the year. He did not have medical insurance through his job and was unable to pay the premiums for an individual plan. His two adolescent children qualified for the State Children's Health Insurance Plan and receive routine medical care. His wife, who also works full-time, has a limited health insurance plan through her employer. When Toby first noticed his symptoms, growing weakness and clumsiness, he went to the emergency room, where a number of tests were administered. He was sent home with no diagnosis. He returned several times, each time complaining that he was getting worse. After his third visit, he was diagnosed with ALS, a neurodegenerative disease that usually attacks both upper and lower motor neurons and causes degeneration throughout the brain and spinal cord. A common first symptom is a painless weakness in a hand, foot, arm, or leg, which occurs in more than half of all cases. Other early symptoms include difficulty in speech, swallowing, or walking. Most commonly, the disease strikes people between the ages of 40 and 70, and as many as 30,000 Americans have the disease at any given time. ALS is progressive and generally fatal (Amyotrophic Lateral Sclerosis Association, 2004). The emergency room physician recommended that Toby apply for Social Security Disability Insurance (SSDI) and Medicaid. Toby did not know about these programs and went to the Social Security Office to ask for an application. This is what he learned about SSDI, Medicaid, and Medicare.

Entitlement Programs: Social Security Disability Insurance, Supplemental Security Income, Medicaid, and Medicare

Social Security Disability Insurance (SSDI) is a public program for people who meet the medical definition of "disability" and who have worked at least 10 years and paid FICA taxes for 5 of the past 10 years of employment. To be considered disabled, a person must prove that he or she is unable to engage in substantial gainful activity for a period that has lasted 12 months or is expected to last 12 months. Once an authorized physician has made the determination that the person is disabled, a benefit based on wages earned over time is calculated. The amount is approximately 85% of the highest wages earned during the past several years. This program is different from Supplemental

CASE STUDY: *Living with Amyotrophic Lateral Sclerosis*   *Continued*

Security Income (SSI). Supplemental Security Income is available to people who meet the statutory definition of disability, are also unable to engage in substantial gainful activity, and are "indigent." This means that they have less than $2,000 in assets and do not have a history of earning substantial wages. The State Children's Health Insurance Program (P.L. 105-33), Title XXI of the Social Security Act, allows states to expand Medicaid eligibility to uninsured low-income children. As a result of the act, states have expanded eligibility to larger numbers of children. For the adult with a disability, the income cap is around $690 per month, depending on the source of income (unearned or earned). Above that cap, the person can be eligible for Medicaid but is responsible for a certain amount of costs per month (called a *spend down*). For example, an adult who receives $1,800 from SSDI would have to spend down about $1,300 each month to qualify for Medicaid. Each of his children would be allocated an exemption, and states have options to exempt various types of incomes and medically necessary expenses.

If the person is eligible for a waiver, the income caps are higher to qualify for Medicaid, but the person must pay a monthly fee (called *cost of care*). Medicaid waivers are authorized under Section 1915(c) of the Social Security Act and allow the Secretary of the U.S. Department of Health and Human Services to waive certain Medicaid statutory requirements. As a result, states can pay for home and community-based services (HCBS) for specific populations. Under the Deficit Reduction Act of 2006, services that once required a waiver may be offered as an optional benefit. However, if states choose to implement this provision, they may also cap the number of people receiving services, which many believe undermines the Medicaid entitlement to services. In many families, as a result, children have health insurance while their parents do not. For example, in New Hampshire, the children can receive "Healthy Kids" Medicaid if the family's income is under 300% of the federal poverty level (based on number of people in the household). For a family of two parents with two children, this is approximately $28,000 per year of income. The adults will not receive Medicaid unless the family is low-income and the adults have a disability.

Individuals are eligible for Medicare if they or their spouses worked at least 10 years and paid payroll taxes and are 65 years of age or in a special disability category. People who have ALS also qualify for Medicare even though they are not 65 years of age. There is a special provision for this population. In these situations, they are eligible for both Medicaid and Medicare. Medicare is a federal public health insurance program provided to every American over the age of 65 and to some other groups, including those who have received SSDI for two years, those with renal failure, and those with

ALS prior to that age. There are other specific groups, as described in regulation, that also qualify. Medicare pays for hospitalizations and medical expenses and, most recently through Part D, prescription drug coverage. It is funded through employee and employer payroll taxes and monthly premiums deducted from Social Security checks. It does not pay for many expenses associated with long-term care.

Toby qualifies for SSDI, according to his physician and the Social Security Office. He is told that the disability determination process will likely take 60 to 90 days, and from that date he will have a six-month waiting period from the time he is deemed eligible to receive his first SSDI check. In the meantime, Toby needs ongoing medical care, including adaptive equipment to help him with daily tasks. He will need a walker and eventually a wheelchair, and he will need physical and occupational therapy in the future. There are also several drugs that were recommended that are very expensive. Toby will have to rely on his wife's wages and their savings until he begins to receive the monthly SSDI check. Toby is eligible for Medicare because he has ALS. He might be able to qualify for Medicaid because he meets the definition of disability. But he must also qualify on the basis of his income (income under $13,330 for a family of three). To qualify, he might have to spend down some of his income, and he must have $2,500 or less in liquidatable assets.

Medicaid

Medicaid, or Title XIX of the Social Security Act, is a state-administered program for people who meet certain eligibility categories and have limited incomes. These categories include children, pregnant women, and individuals with disabilities and/or over the age of 65 years. The federal government matches the state allocation, using a complicated formula based on the state's demographic characteristics. The Medicaid program was not designed for people who are simply poor. They must also be in one of the eligible categories. The Kaiser Commission (2006) reported that in 2005, Medicaid provided insurance coverage to 52 million individuals. Its budget has grown by one third since 2001. The growth is related to an increase in the number of people in poverty and those without private health insurance. The following are categorically needy groups (Centers for Medicaid and Medicare Services, 2006):

- Individuals who meet the Aid to Families with Dependent Children (AFDC) program that were in effect in their state on July 16, 1996
- Children under age 6 years whose family income is at or below 133% of the federal poverty level (FPL)
- Pregnant women whose family income is below 133% of the FPL (Services to these women are limited to

Continued

CASE STUDY: *Living with Amyotrophic Lateral Sclerosis*   *Continued*

those related to pregnancy, complications of pregnancy, delivery, and postpartum care.)

◆ Supplemental Security Income (SSI) recipients in most states (Some states use more restrictive Medicaid eligibility requirements that predate SSI.)

◆ Recipients of adoption or foster care assistance under Title IV of the Social Security Act

◆ Special protected groups (typically individuals who lose their cash assistance due to earnings from work or from increased Social Security benefits but who may keep Medicaid for a period of time)

◆ All children born after September 30, 1983, who are under age 19 years and are in families with incomes at or below the FPL

◆ Certain Medicare beneficiaries

There are also optional groups (CMS, 2006) to which states can elect to provide Medicaid coverage. They include the following:

◆ Infants up to age 1 and pregnant women not covered under the mandatory rules whose family income is no more than 185% of the FPL (the percentage amount is set by each state)

◆ Children under age 21 who meet criteria more liberal than the AFDC income and resources requirements that were in effect in their state on July 16, 1996

◆ Institutionalized individuals eligible under a "special income level" (the amount is set by each state—up to 300% of the SSI federal benefit rate)

◆ Individuals who would be eligible if institutionalized but who are receiving care under HCBS waivers

◆ Certain aged, blind, or disabled adults who have incomes above those requiring mandatory coverage but below the FPL

◆ Recipients of state supplementary income payments

◆ Certain working and disabled individuals with family income less than 250% of the FPL who would qualify for SSI if they did not work

◆ TB-infected individuals who would be financially eligible for Medicaid at the SSI income level if they were within a Medicaid-covered category (However, coverage is limited to TB-related ambulatory services and TB drugs.)

◆ Certain uninsured or low-income women who are screened for breast or cervical cancer through a program administered by the CDC. The Breast and Cervical Cancer Prevention and Treatment Act of 2000 (P.L. 106-354) provides these women with medical assistance and follow-up diagnostic services through Medicaid

◆ "Optional targeted low-income children" included within the State Children's Health Insurance Program established by the Balanced Budget Act of 1997 (P.L. 105-33)

◆ "Medically needy" individuals

Because each state designs and administers it own programs, eligibility and benefits vary. A person could be eligible in one state and found to be ineligible in another. In addition, a person could receive one set of services in one state and a different set in another. Medicaid pays for medical services, both acute and long-term care. This includes the following:

◆ Inpatient hospital services
◆ Outpatient hospital services
◆ Prenatal care
◆ Vaccines for children
◆ Physician services
◆ Nursing facility services for persons aged 21 years or older
◆ Family-planning services and supplies
◆ Rural health clinic services
◆ Home health care for individuals who are eligible for skilled nursing services
◆ Laboratory and X-ray services
◆ Pediatric and family nurse-practitioner services
◆ Nurse-midwife services.
◆ Federally qualified health center services
◆ Early and periodic screening, diagnostic, and treatment services for children under age 21 years

States may also choose to receive federal Medicaid matching dollars for optional services. These include diagnostic services, clinic services, intermediate care facilities for the mentally retarded, prescribed drugs and prosthetic devices, optometrist services and eyeglasses, nursing facility services for children under age 21, transportation services, occupational and physical therapy services, home and community-based care to certain individuals with chronic impairments, and others (CMS, 2006). The level of reimbursement for these services varies. In some cases, private physicians will refuse to see Medicaid recipients because the reimbursement for their care is less that 25% of the cost of providing the services. This is a huge barrier to accessing good-quality health care, including dental care.

Currently, Toby is not able to qualify for Medicaid services based on the state plan. He has too many assets and has been saving for his children's education. His wife's income is also deemed to be available to him. To receive Medicaid services, he will have to spend down his savings. His house and vehicle do not count against his assets. His anticipated monthly SSDI check will not be more than approximately $1,800 per month. He will quickly become indigent as his nonreimbursable medical costs increase with his illness. At that point, he will qualify financially for Medicaid. Toby's doctors told him that he could end up in a nursing home. He does not want this. He wants to remain at home with his family and receive care there. A state Medicaid program designed through an option called the Elderly and Chronically Ill (ECI) Waiver pays for

CASE STUDY: *Living with Amyotrophic Lateral Sclerosis*   *Continued*

long-term care expenses and could help him. Toby calls the Medicaid Office to inquire about getting waiver services. He has been told that in his state, the limit for home and community-based care under the ECI Waiver is that the cost of services has to be less than 50% of what it costs for a nursing home. This means that if his services exceed the 50% limit, he will have to go to a nursing home to receive the necessary care, even if it can be provided at home. Some critics refer to this as the institutional bias in the Medicaid program. Because Toby has a disability, he can receive Medicaid but will have to spend down his assets over time to remain qualified.

Community-Based Care

The fields of disabilities, chronic illness, and aging have seen numerous changes over the past decade. This ideological and legislative trend away from institutionalization toward home and community-based services has been only partially supported by fiscal policies with major incentives in Title XIX (Grants to States for Medical Assistance) and Title XVIII (Health Insurance for the Aged and Disabled) of the Social Security Act programs and fiscal structures that support institutional care. Resource allocation has varied extensively with groups and across states not necessarily favoring community supports. The imbalance has produced an institutionalized population of people with developmental disabilities as well as numerous elders in nursing homes. It has also established a divided set of interests within the professionals and direct care staff employed in this arena. There is a powerful nursing home lobby in this country that has rejected removing the institutional bias in the Medicaid program. People in need of long-term services and supports desperately need some alternative in order to overcome the current institutional funding biases. Under the Deficit Reduction Act (2005), states can provide home and community-based services as part of their state plan without seeking a specific waiver to do so. This has the potential to improve the availability of home and community-based care and remove the institutional bias in Medicaid services. However, there are ongoing efforts to restrict the entitlement to Medicaid because of its rapid growth.

Toby realizes that he and his family face significant challenges. He has sought assistance from an ALS support group, which meets monthly. He feels as though he is learning more about the disease and his disability. One of the group members suggested that he contact the Independent Living Center to help with benefits counseling and personal assistance services. These services consist of formal and informal help provided to people with disabilities to assist them in activities of daily living. The Independent Living Center provides personal assistance services. The group also suggested that Toby contact the Assistive Technology Center to learn about devices

that might help him. He contacts both and is provided with numerous ideas and supports for the present and the future.

Contemporary Disability Policy: Independent Living, Inclusion, and Choice

The core values of contemporary disability policy are based on independent living, equal opportunity, self-determination, community inclusion, and participation. Statutes at the federal and state levels widely embody principles of nondiscrimination; least restrictive environment; access to education, employment, and housing; and consumer direction and control. The Americans with Disabilities Act (1990) promotes access to public and private facilities and programs while prohibiting discrimination against people with disabilities. Many states have already included statutory language in legislation affecting people with disabilities and those who are aging that ensure consumer choice, control, and planning. In 1999, the U.S. Supreme Court ruled in *Olmstead v. L. C. & E. W.* (1999). Writing for the majority, Justice Ruth Bader Ginsburg said that under Title II of the federal Americans with Disabilities Act, "states are required to place persons with mental disabilities in community settings rather than in institutions when the State's treatment professionals have determined that community placement is appropriate, the transfer from institutional care to a less restrictive setting is not opposed by the affected individual, and the placement can be reasonably accommodated, taking into account the resources available to the State and the needs of others with mental disabilities."

This court ruling as well as other state legal cases provided the needed impetus to motivate states to develop "Olmstead Plans" that identified barriers to living independently in the community. These barriers, attitudinal, fiscal, and policy-related, are being addressed in a systematic fashion in many states. More and more people are rejecting nursing home care and other forms of institutionalized care in favor of home and community-based options. Furthermore, they seek more control over the services and supports that they do receive. New solutions such as personal assistance services, cash and counseling, and self-directed services and supports are being developed throughout the United States. Cash and Counseling, for example, is a program that provides dollars in the form of vouchers to individuals who want to purchase their own services outside of the service system that exists.

Other laws and policies support the principles of inclusion and self-determination. The Individuals with Disabilities Education Improvement Act (2006) promotes access to general education curricula for students with disabilities. The Rehabilitation Act of 1973 prohibits discrimination by entities that receive federal assistance from discriminating on the basis of disability. Title VII of the Act authorized the creation

Continued

CASE STUDY: *Living with Amyotrophic Lateral Sclerosis*   *Continued*

of Independent Living Centers: nonresidential, community-based not-for-profit agencies run by and for people with disabilities that provide peer support, advocacy, independent living skill training, and information and referral. The development of these centers empowered members of the disability community to identify and help to develop policy solutions to existing policy barriers and gaps in services. Many centers provide assistive technology, equipment repair, personal assistance services, and housing assistance, including home modification. This ability was enhanced by the Technology-Related Assistance for Individuals with Disabilities Act of 1988, which "provides financial assistance to States to undertake activities that assist each State in maintaining and strengthening a permanent comprehensive statewide program of technology-related assistance, for individuals with disabilities of all ages, that is designed to increase the availability of, funding for, access to, and provision of, assistive technology devices and assistive technology services." Access to assistive technology enables many individuals to participate more fully in education, employment, and the community. Yet it does not necessarily address issues related to universal design. Mace, Hardie, and Place (1991) defined *universal design* as the design of products and environments to be usable by all people, to the greatest extent possible without the need for adaptation or specialized design. One area in which universal design has been applied is housing. Houses are being designed so that people who use wheelchairs or need mobility support can get in the front doors and use the bathrooms and kitchens. The visitability movement acknowledges that our houses should be able to accommodate our aging relatives and friends who have disabilities. (See Chapters 19 and 61 for more on visitability.)

It is three years since Toby was diagnosed with ALS. He is now using a wheelchair and needs assistance in dressing and eating. His disease seems to have slowed in the last three months. Because of excessive medical expenses, over a year ago Toby qualified for Medicaid and was able to qualify for the HCBS waiver under the ECI Waiver offered by the state. He continues to receive Medicare, which does not adequately cover all of his medical expense, and even with the new Medicaid prescription drug option (Part D), he must pay out of pocket for many of the prescriptions and generic drugs he needs. Under the waiver, he is receiving nursing and home health services in his home. However, under the waiver, he can receive only a maximum of $16,000 per year for all of his services. The home health agency bills the state for services at $30.00 per hour. This means that Toby can receive only 533 hours of services per year, or 44 hours of service each month. Toby's wife and children are helping out as well, but the amount of service is insufficient for his needs. His wife has to keep her full-time paid employment to pay expenses.

Additionally, there have been many times when a nurse has not been available. There are frequent changes in personnel, and on several occasions, Toby's wife has had to be late or miss work to care for Toby. His extended family provides some help, but they are unable to fill in all of the gaps. Toby and his wife, with support from the Independent Living Center, are directing their own services and have decided that the nursing level of care is not necessary. They are arranging to have a personal care assistant under the Consumer Directed Care Option provide the support at half the cost of home health services. This means that Toby and his family will receive approximately twice as much service, or 88 hours each month. They wonder how long they can get by with only 22 hours of service each week.

Transportation is also a problem. Although the family has a van, it is the only vehicle. When Toby has a medical appointment, his wife must take a day off from work, or Toby must use specialized transportation services. Going out simply to get out of the house when his wife is working is almost impossible because of lack or either fixed route or para-transit accessible transportation. Toby is essentially homebound.

Self-Direction and Consumer Directed Care

Control over one's life has been positively correlated with good health and self-esteem. Wagner, Nadash, Friedman, Litvak, and Eckels (1996) articulated principles of consumer-directed home and community-based services for elders and people with disabilities. Wehmeyer and Schwartz (1997) found in a follow-up study that young adults with mental retardation who exhibited more self-determined behaviors were more effective problem solvers; were more assertive and self-aware; and held significantly more adaptive perceptions of control, self-efficacy, outcome expectancy, and self-esteem. These findings have been supported by others studying empowerment and general health status. Therefore, the design of any public health system should reduce people's dependency on formal medical structures and integrate principles of consumer control and self-determination. Cash and Counseling is a nationally recognized approach that provides Medicaid participants the ability to directly pay for their own supports and services through a voucher-like system with support from service coordinators or case managers. In an evaluation of three state Cash and Counseling demonstration projects (Dale, Brown, & Shapiro, 2005), participants cited the following reasons for participation: more control over the hiring of caregivers, hiring family and friends, receiving care at more convenient times, and more and better-quality care. Cash and Counseling has been implemented in three states and is now being replicated with support from the Robert Wood Johnson Foundation in an additional 12 states. The approach to service delivery is supported by the CMS through the Independence Plus Waiver. This waiver was specifically informed

CASE STUDY: *Living with Amyotrophic Lateral Sclerosis*   *Continued*

by the Cash and Counseling Demonstrations as well as the Self-Determination demonstrations that were implemented in 12 states. CMS reports that: "these programs afforded service recipients or their families the option to direct the design and delivery of services and supports, avoid unnecessary institutionalization, experience higher levels of satisfaction, and maximize the efficient use of community services and supports" (CMS, 2006). For states to receive an Independence Plus Waiver, they must include the following components in their Medicaid Plan:

- ◆ **Person-centered planning:** A process, directed by the participant, intended to identify the strengths, capacities, preferences, needs, and desired outcomes of the participant.
- ◆ **Individual budgeting:** The total dollar value of the services and supports, as specified in the plan of care, under the control and direction of the program participant.
- ◆ **Self-directed services and supports:** A system of activities that help the participant to develop, implement, and manage the support services identified in his or her individual budget.
- ◆ **Quality assurance and quality improvement (QA/QI):** The QA/QI model will build on the existing foundation, formally introduced under the CMS Quality Framework, of discovery, remediation, and continuous improvement (CMS, 2006).

Toby is requiring more and more care. He has made clear that he does not want to go to a nursing home. He is having difficulty swallowing, and he is using some alternative feeding methods. He has for several years used nighttime breathing support. His doctors believe that he will not survive for more than three more months. His children, now in college, visit frequently. His wife continues to work. Medicare is paying for his in-home medical care. Medicaid is paying for personal assistance services. Toby remains in control of his life and the decisions about his care.

Conclusion

Toby and his family have had to traverse the complicated health care and social service systems. The lack of coordination of care by human service agencies and the lack of access within the community have challenged the family's intellectual, physical, and financial resources. However, new models that emphasize self-direction, community engagement, and coordinated care can provide new opportunities for professionals and people with disabilities to work together to achieve better public policies that result in better health outcomes for all people. These models are part of a larger public health system that remains fragmented, difficult to traverse, and focused on treatment rather than prevention. Changes to these systems will be made only through organized advocacy efforts on behalf of and with people who lack health insurance and need community-based personal assistance services and income support programs. There are powerful interests that must be organized before there is any fundamental shift in our nation's health care system.

Health Promotion

18

LORI LETTS

Learning Objectives

After reading this chapter, you will be able to:

1. Understand definitions and approaches to health.
2. Become familiar with common terminology used in relation to health and health promotion.
3. Understand the principles and process of health promotion.
4. Understand how occupational therapists can be involved in promoting health.

INTRODUCTION

Health promotion seems like something that occupational therapists should be able to do quite easily. The goal of the profession is to promote health through engagement in meaningful occupations. This goal applies equally to people who are experiencing challenges in occupational performance, people with disabilities, and those who are healthy and independent. Because occupational therapy is premised on the importance of health through occupation, it seems natural for occupational therapists to be involved in health promotion; to promote health through meaningful engagement in occupation for all. However, health promotion is understood in many different ways, as is health itself. The purpose of this chapter is to provide definitions of health, health promotion, and related terms and to share ideas on how occupational therapists can apply the principles of health promotion in practice.

DEFINITIONS OF HEALTH

Health can be defined in many ways, although the definition from the World Health Organization (WHO) is probably the most frequently cited: "health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (WHO, 1948).

Although frequently cited by many involved in health care and health promotion, the WHO definition of health has also been criticized. Seedhouse (2001) notes numerous problems with this definition. It implies that people cannot be healthy if they have a disease or infirmity; the definitions of physical, mental, and social well-being are unclear; and the definition of health is so ideal that it is impossible to achieve. Callahan (as cited in

Raeburn & Rootman, 1998) has suggested that the WHO definition of health has threatened the direction and costs of health services by suggesting that anything can be related to health. Nursing and academic definitions of health tend to be multidimensional, with emphasis on biopsychosocial components (Raeburn & Rootman, 1996). Evans and Stoddart (1990) suggest that definitions of health can be placed on a continuum with the WHO definition at one end and the traditional absence of disease definition at the other.

APPROACHES TO HEALTH

Depending on how health is understood, and even if the WHO definition is accepted, there are varying ways to approach health. Labonte (1993) provides a framework to describe how different understandings of health lead to different actions or approaches to address health problems. These include medical, behavioral, and socioenvironmental approaches to health. Labonte notes that the distinctions between these approaches are not always clear; nor do health professionals subscribe to one approach only. Rather, they represent global approaches that shed light on the various ways in which health problems are understood and addressed. These are summarized in Table 18.1.

The Medical Approach to Health

In the medical approach, health problems are understood primarily in relation to disease states, including common health problems such as cancer, cardiovascular disease, diabetes, mental illnesses, hypertension, and AIDS, as well as injuries that need to be treated in emergency departments. The medical approach to health promotion identifies risk factors for these disease states and works to prevent the diseases by decreasing the risk factors. This is done through interventions such as medications, illness care in hospitals, physician-supervised smoking reduction or diet regimens, and screening for other risk factors such as cholesterol or blood pressure levels. In terms of **prevention**, the focus of the medical approach is on preventing a person from becoming more ill or dying, which is sometimes referred to as *tertiary prevention.* The medical approach focuses on outcomes such as morbidity rates, mortality rates, and decreased prevalence of risk factors for disease (Labonte, 1993).

Occupational therapists working with people with posttraumatic hand injury or rehabilitation centers for people who have had strokes often adopt a medical approach to health. In many situations, this is very appropriate, since clients come to therapists with an acute or recent injury that is amenable to intervention; to assist them to return to their preinjury state. Splints, work conditioning, and constraint-induced movement therapy may all be interventions that are adopted by occupational therapists working from a medical approach to health.

The Behavioral Approach to Health

A behavioral approach to health focuses on individual lifestyle choices, health often being closely linked to wellness. Health problems are primarily related to behavioral risk factors, and this approach addresses behaviors such as smoking, poor fitness, drug and alcohol abuse, or limited abilities to cope with stress. The behavioral approach

TABLE 18.1   APPROACHES TO HEALTH

Approach	Medical	Behavioral	Socioenvironmental
Health definition	Biomedical; absence of disease or disability	Individualized; physical functional ability, physical well-being	Positive state; ability to do things that are important and have meaning
Targets for health initiatives and health problems	Individuals with health problems or at high risk for health problems such as cancer, diabetes, obesity	Individuals at high risk for health problems and children, to deal with health problems such as smoking, lack of fitness, limited life skills	High-risk conditions or environment with health problems such as poverty, unemployment, pollution, hazardous working conditions.
Strategies to improve health	Treating health problems through: surgery, drugs, illness care, medically managed behavior changes	Improving lifestyles or creating healthy lifestyles through health education, social marketing, advocacy for public policies supporting lifestyle choices	Creating healthy environments and creating healthy lifestyles through: personal empowerment, community organization, small group development, political action, coalition advocacy

involves health education, stress management or coping skills training, social marketing to help people make healthier lifestyle choices that will in turn improve their health, and encouraging children to adopt healthy lifestyles from early stages of life. Strategies are often implemented at the level of communities, although most frequently, health concerns are identified and strategies are developed by professionals. If the focus of the intervention is on preventing disease or injury by changing unhealthy behaviors, this is referred to as *secondary prevention.* If the focus is on developing and maintaining healthy behaviors, this is *primary prevention.* Success is benchmarked on the basis of behavioral changes and reducing behavioral risk factors (Labonte, 1993).

The American Occupational Therapy Association (AOTA) (2001) provides numerous examples that illustrate strategies to address health through a behavioral approach, including (to name only a few) educating and training to prevent secondary disabilities through such strategies as regular blood sugar checks and foot inspections for people with diabetes, educating caregivers about proper body mechanics for lifting a family member with a disability, teaching self-management to people with chronic conditions, and leading falls prevention sessions with older adults.

The Socioenvironmental Approach to Health

The socioenvironmental approach to health focuses on health as a positive state that has as a major priority social connections to family, friends, and communities. Health problems are understood as being tied to environmental risk conditions and psychosocial risk factors. Examples of risk conditions include poverty, limited education, unemployment, and hazardous living or working conditions. Psychosocial risk factors include such things as isolation, stress, and limited social networks. Labonte (1993) discusses five strategies to address health problems from the socioenvironmental perspective: personal care, small group development, community organization, coalition building and advocacy, and political action. These will be discussed later in this chapter specifically related to health promotion. The socioenvironmental approach is focused on primary prevention (creating healthy lifestyles) and health promotion (creating healthy living conditions). Success from a socioenvironmental perspective is based on indicators such as environmentally sustainable practices at personal and public levels, improved social networks, and more equitable social distribution of power and resources (Labonte, 1993).

Many occupational therapists who work with community organizations have adopted a socioenvironmental approach to health. For example, the Canadian Association of Occupational Therapists (CAOT) Seniors' Health Promotion Project (Letts, Fraser, Finlayson, & Walls, 1993) included initiatives such as an oral history program in which senior volunteers, trained by the occupational therapist, visited and collected oral histories from homebound seniors in Newfoundland. The aims of the oral history program were to address social isolation for homebound seniors and to foster skill development for the senior volunteers. In Manitoba, the occupational therapist provided an educational workshop to staff in a community recreation center to enable the inclusion of older adults with disabilities into the regular recreation programming at the center.

The three approaches to health described here are complementary. They can be applied in various ways to meet health goals. Problems are more likely to arise when too many resources are devoted to one approach to the detriment of the others. The following parable illustrates this point and demonstrates the value of each of the three approaches.

THINKING UPSTREAM: A POWERFUL METAPHOR

A number of health promotion documents cite a metaphor to explain how health promotion can be conceived as being different from traditional medical approaches to health. The metaphor, although varied depending on its source, can also be used to illustrate the different approaches to health described by Labonte (1993) and how each has its own place in efforts to optimize health for individuals and communities.

> One day a group of villagers was working in the fields by the river. Suddenly, someone noticed a man coming downstream, flailing in the water. A group of people rushed out and rescued the man and brought him to shore. One woman who helped rescue him brought him home to care for him.
>
> The next day, there were two people, a man and a woman flailing in the water, and the people who rescued them took them home to care for them. On the third day, there were three people. Before long, there was a steady stream of people needing rescue downstream. Soon the whole village was involved in the business of pulling flailing people out of the stream and ensuring that they were rehabilitated.
>
> One day someone decided to go upstream to find out how or why the people were ending up in the river. A huge controversy erupted. One group argued that every possible hand was needed to save the people in the river, since they were barely keeping up with the current flow. Others argued that if they found out how people were ending up in the water, they could stop them and would not need to rescue people anymore—or at least not with the same frequency. (Saskatoon District Health Community Development Team and Dr. Ron Labonte, 1999, p. 1. Adapted with permission from Prairie Regional Health Promotion Research Centre.)

This parable can be used to illustrate the different approaches to health that were previously described. A

medical approach would result in action that the people downstream first implemented; that is, providing treatment and rehabilitation to people who were rescued from the river. Using a behavioral approach, there might be attempts to provide secondary prevention to people after their recovery. For example, people could be taught to swim after their rescue so that they do not have to flail in the water; they could be instructed to behave in safer ways so that they do not fall in; or the rocks in the water could be removed or padded so people will not be hurt when they fall in. At a primary prevention level using a behavioral approach, the focus would be on helping young children to live healthy lifestyles, including swimming and overall fitness so that they could better cope if they fell in, and teaching them safe water practices early in their lives. From a socioenvironmental approach, the focus at the primary prevention level would be on promoting healthy lifestyles in young children. It would also include a focus on the circumstances that result in people falling in the river. For example, are the docks poorly designed? Are people forced to work close to the water's edge for their very survival? What can be changed in their setting to make their survival possible without putting them at risk of falling in the water?

The parable also illustrates the need to consider the "upstream" issues related to health problems, regardless of the approach that is taken to address health. All three approaches consider risk factors for health problems, although they take different perspectives on how risk is defined and understood. Regardless, there is acceptance of the need to consider the sources of health problems. In recent years, the **determinants of health** have received significant attention in the literature and in the fields of **public health** and health promotion. Exploring the determinants of health is a way to look upstream, to better understand the source of health problems.

DETERMINANTS OF HEALTH

Considering the need for upstream thinking and the various approaches to health, it is important to understand the factors that determine what makes people healthy. If these factors can be identified, multiple sectors and approaches can be mobilized to improve the health of individuals and communities.

Health is determined by many factors. In a U.S. national report entitled *Healthy People 2010,* determinants of health are described within six broad categories: biology, behaviors, social environment, physical environments, policies and interventions, and access to high-quality health care (U.S. Department of Health and Human Services, 2000). A number of goals and objectives relate to the overall health of the nation and are relevant to occupational therapy. For example, objectives focus on reducing the proportion of adults with chronic joint symptoms who experience a limitation in activity due to arthri-

tis and increasing the proportion of adults with disabilities who participate in social activities. In *Healthy People 2010,* health disparities are acknowledged, although they are not labeled as determinants of health. Significant health differences or disparities are noted among groups of people based on their gender, race and ethnicity, income and education, disability, geographic location, and sexual orientation. While these are not described as determinants of health in this report, there are clear differences between groups of people based on these factors. Other documents have described many of these factors as key determinants of health (Hamilton & Bhatti, 1996; WHO Regional Office for Europe, 2002). Lists of the determinants of health frequently include the following factors:

◆ Income and social status
◆ Social supports
◆ Gender
◆ Education
◆ Working conditions
◆ Physical environments
◆ Air quality
◆ Food safety
◆ Water
◆ Biology and genetics
◆ Personal health practices and coping skills
◆ Nutrition
◆ Physical activity
◆ Healthy child development
◆ Health services

Research and information related to the determinants of health are often found in literature related to **population health**. Population health data can help policymakers to identify the major factors within a community that are contributing to health challenges and may lead to policies and initiatives to promote health.

HEALTH PROMOTION

The determinants of health can be used as a foundation to consider how health can then be promoted. *Health promotion* is a term that has received significant attention from the World Health Organization and nations around the world. Health promotion has commonly been defined as the "process of enabling people to increase control over and improve their health" (WHO, 1986, p. 2). Although the definition of health promotion does not directly acknowledge determinants of health, the Ottawa Charter identifies prerequisites for health which include "peace, shelter, education, food, income, a stable eco-system, sustainable resources, social justice and equity" (WHO, 1986, p. 2). Clearly, some of the environmental and social determinants of health are considered so vital to health that they are in fact prerequisites, factors that are foundational to any improvements in health.

The Ottawa Charter includes three strategies that can be implemented in health promotion initiatives: advocacy for conditions that are favorable for health, enablement of people to achieve their health potential, and mediation between differing interests in society. The Ottawa Charter also describes five areas of health promotion action: build healthy public policy, create supportive environments, strengthen community action, develop personal skills, and reorient health services.

Principles

Underlying the definition, strategies, and actions of health promotion as described in the Ottawa Charter (WHO, 1986) are a number of principles related to health promotion that are not explicitly stated in the charter. These principles have been articulated by others, including de Leeuw (1989) and Thibeault and Hebert (1997).

The first principle relates to *community participation.* Health promotion needs to involve community members throughout all phases, from identifying the health issue of concern to determining how best to address it and then to evaluating whether or not it has been addressed. At heart, health promotion is participatory. All phases of health promotion processes involve community participation as an integral component.

The second principle of health promotion relates to *empowerment,* which is linked closely with the first principle of community participation. Empowerment implies that people and communities that are involved in health promotion processes will gain knowledge and skills and, through that, a sense of self-efficacy and empowerment. While Labonte (1994) notes that health promotion can sometimes become bureaucratic and disempowering, the underlying purpose of health promotion initiatives should be community participation and ownership so that empowerment occurs.

Underlying the principles of community participation and empowerment is a principle of *respect for diversity.* Groups and communities that are interested in participating in health promotion processes are very diverse and may represent groups that face marginalization for a number of reasons, such as age, race or ethnicity, or sexual orientation. Health promotion involves respect for all stakeholders in addressing a health issue and respect for diversity that occurs within and between communities.

Social justice is another underlying principle of health promotion. Many of the social determinants of health, such as poverty, education, and discrimination based on race or gender, can best be addressed through social justice initiatives. In occupational therapy, Townsend and Wilcock (2004) describe *occupational justice* and suggest that it is related to, but distinct from, social justice. They describe social justice as "a concept that recognizes humans as social beings who engage in social relations" and suggest that advocacy in social justice "favors equitable (same) access to opportunities and resources in order to reduce group differences" (Townsend & Wilcock, 2004, p. 262). Occupational justice is "a concept to guide humans as occupational beings who need and want to participate in occupations in order to develop and thrive" with the advocacy related to "enablement of different access to opportunities and resources in order to acknowledge individual differences" (Townsend & Wilcock, 2004, p. 262). Occupational therapists who are involved in health promotion aim for social justice in trying to ensure access to opportunities that are equitable across and between groups (social justice) and those that meet the unique needs of individuals (occupational justice). (See Chapter 20 for an in-depth discussion of occupational justice).

The determinants of health go well beyond the health sector alone. Health care services can contribute to improved health, but other sectors are also key stakeholders and need to be involved in initiatives to improve health. For example, the availability and accessibility of transportation systems in large urban centers can influence people's abilities to access education, recreation, and employment. The media can have significant involvement in health promotion initiatives through public service announcements. Schools can also play significant roles in influencing health and addressing health issues. Because health is influenced by many sectors, health promotion initiatives are best implemented if they are *intersectoral.* For example, addressing the social isolation of older adults might involve transportation systems, cultural and religious organizations, social services, welfare, and housing.

Health promotion is also an *integrative* process, one that includes many strategies to address the health concern, including education, legislation, and **community development**. For example, workplace health promotion involves legislation through laws that ensure basic workplace safety, organizational policies (e.g., through employee assistance programs), educational initiatives (e.g., safe lifting in-service workshops), as well as organizational initiatives to create a collaborative workplace based on principles of respect and empowerment.

Finally, health promotion is *continuous.* Ideally, successful health promotion initiatives will result in strengthened communities and healthy public policy that can lead to further initiatives to promote health either by addressing new health issues or by building on one initiative to create another to further address the original issue. Practitioners who are committed to health promotion need to be committed to change (Letts et al., 1993). While occupational therapy practitioners do not necessarily have to be involved in all health promotion initiatives after one interaction with a group or community, they need to understand that health promotion is seldom constrained to one activity or initiative.

Process

Health promotion should be considered a process rather than a specific one-time standardized intervention. The

stages of the process are not always clearly defined, but common elements or phases of health promotion can be described. Letts and colleagues (1993) described the initial phases of the health promotion process as including the following:

◆ Networking (within communities to identify stakeholders and communities or sectors)
◆ Consulting (to identify health issues)
◆ Collaborating (to select a specific health issue to address) and
◆ Planning (to specifically plan actions and develop objectives).

Actions are then implemented in partnership and can be evaluated by the group. Raeburn and Rootman (1998) describe a thirteen-step process of engaging in people-centered health promotion, from beginning initial consultations, conducting needs assessment, setting goals, planning resources and actions, and evaluating progress. The overall process of health promotion generally includes a process of consulting a community or group to identify the health issue (epidemiological or community statistics can also provide information about health issues), conducting needs assessments, identifying priorities, and planning actions in partnership with communities to address the identified health issue.

Approaches to Health Promotion

How can the ideas of the Ottawa Charter (WHO, 1986) and the principles of health promotion be implemented with individuals, groups, and communities? What does it look like, and how should occupational therapists be involved? The notions of enablement, mediation, and advocacy as described in the Ottawa Charter provide a place to begin. Within a health promotion framework, occupational therapists can use their skills and knowledge in numerous ways.

Wilcock (1998) suggests five models that represent different but not mutually exclusive approaches to health promotion. These include wellness, preventive medicine, community development, social justice, and ecological sustainability. These approaches range from individually focused initiatives to help people make healthier choices (wellness) through community-based consultations that promote communitywide responsibility for health (community development), to initiatives at the global level to promote healthy relationships between humans and all other organisms to sustain life on the planet (ecological sustainability).

McComas and Carswell (1994) developed a model to describe the process for health promotion action based on an initiative with women with disabilities. Their model was based on Labonte's (1994) framework for health professionals to think about how to apply health promotion concepts in practice, ranging from strategies of individual empowerment, through small group development, commu-

nity organization, coalition advocacy, and political action. The Labonte model has similarities with the Wilcock (1998) model in that there is a range from individual focus to broader focus, although Labonte does not address the health of the planet.

Labonte's (1994) model described the empowerment strategies as following a continuum from working with individuals who face health challenges to political advocacy to address health inequities. He described the model as a holosphere, with each strategy as a sphere overlapping with the others. In working with individuals, for example, Labonte notes that personal care for individuals based on health promotion principles would be supportive and noncontrolling, with health professionals providing information and resources to individuals. Group development involves helping groups of individuals to organize around their health issues. Health professionals need to be aware of groups that might be appropriate to refer individual clients but also be willing to act as a facilitator or guest. Community organization involves groups of people coming together as communities to address health issues. Although health professionals may be involved in such initiatives, Labonte cautions them to ensure that this does not become bureaucratic. Coalition advocacy occurs when links between organizations are formed to address health issues through advocacy, by linking communities around a common interest to change structures or policy. Political action is often the next step after coalition advocacy and frequently involves conflict and a need for someone to take a role as facilitator in organizing collaboratively.

Building on Labonte's ideas, McComas and Carswell (1994) suggest that the actions can be thought of as a series of circles that become increasingly large as the initiatives expand and build on one another. Further, the notions of participation, supportive environments, personal and group control, and personal competence suggest underlying principles or foundations that need to be in place for the process of health promotion action to be successful (Figure 18.1).

The process for health promotion action as described by McComas and Carswell (1994) provides a way for occupational therapists to consider how their knowledge and skills can be applied at many different levels through health promotion. It also demonstrates how the different approaches or levels of action are related to one another. Further examples of initiatives by occupational therapists will be described later in the chapter.

CONCEPTS RELATED TO HEALTH PROMOTION

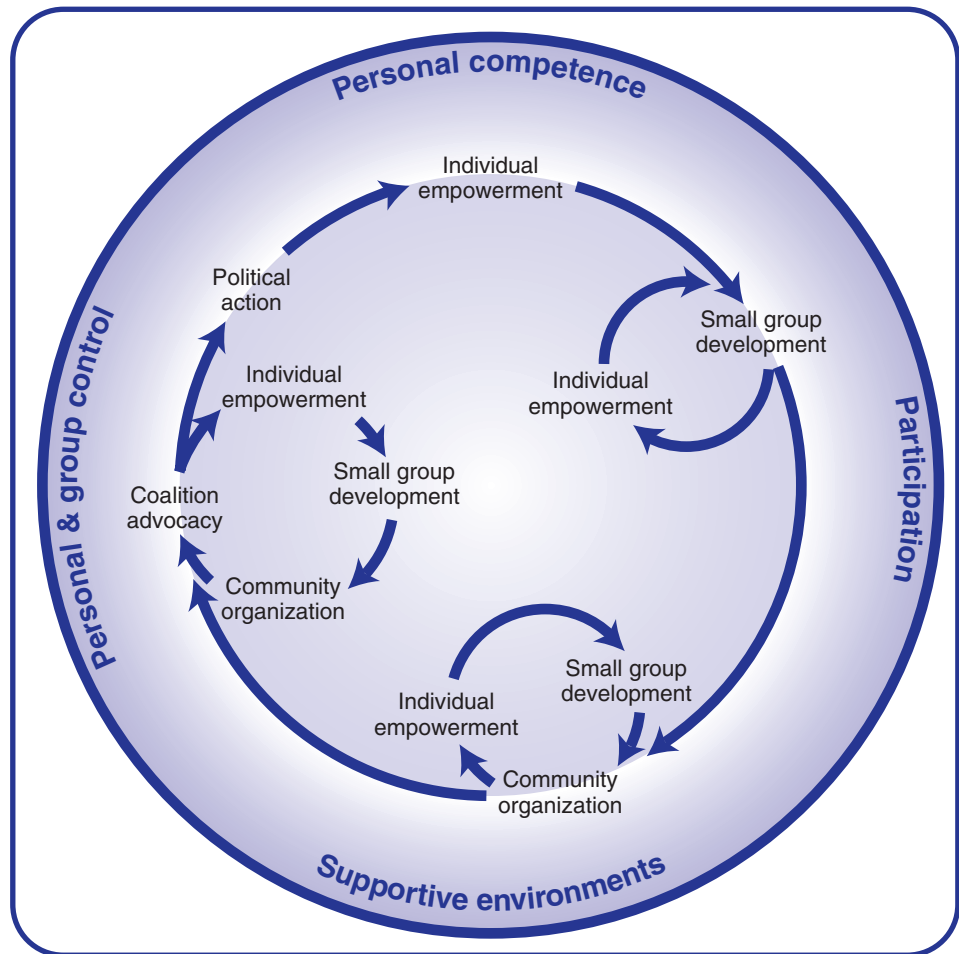
This section provides a summary of terms that are commonly used in conjunction with health promotion, their most common use, and key points about their links to health promotion. A helpful resource on health promotion termi-


FIGURE 18.1   Process for health promotion action.

nology is the *Health Promotion Glossary,* which was written by Nutbeam (1998) for the World Health Organization.

Population Health

Most recently, population health has been strongly associated with research on the determinants of health, in particular the work of Evans, Barer, and Marmor (1994) and Evans and Stoddart (1990). Population health has been defined as "the health outcomes of a group of individuals, including the distribution of such outcomes within the group" (Kindig & Stoddart, 2003, p. 381). The focus of population health research tends to be on health indicators or outcomes at the level of populations and is frequently conducted by epidemiologists.

Critiques of population health have noted that it attempts to be nonpolitical while providing justification for reduced funding to the health care sector without necessarily calling for reallocation of those funds to address social determinants of health (Robertson, 1998); it does not adequately attempt to understand the underlying social conditions that result in the differences between groups of people in health and it does not provide a vision for how

changes can be made at the level of individuals or communities (Coburn et al., 2003).

Hamilton and Bhatti (1996) describe the complementary nature of population health and health promotion, highlighting the importance of considering the determinants of health to understand health issues that might be addressed through health promotion initiatives. Their three-dimensional model describes the link between determinants of health, levels of activity, and the five strategies articulated in the Ottawa Charter for Health Promotion (WHO, 1986). However, what are missing from Hamilton and Bhatti's discussion are some of the underlying principles of health promotion that were discussed previously in this chapter, including community participation, empowerment, and social justice. Although they are related and probably complementary concepts, population health and health promotion are distinct from one another.

Public Health

Health promotion has its roots in public health. Nutbeam (1998, p. 3) has defined public health as "a social and political concept aimed at improving health, prolonging life and

improving the quality of life among whole populations through health promotion, disease prevention and other forms of health intervention." Public health incorporates health promotion but also health protection, through such things as restaurant inspections and disease prevention through childhood immunization programs.

Primary Health Care

Primary health care, defined by the World Health Organization in 1978, is "essential health care made accessible at a cost a country and community can afford, with methods that are practical, scientifically sound and socially acceptable" (Nutbeam, 1998, p. 3). More recently, primary health care reform has been underway in a number of countries, including the United Kingdom, Canada, Australia, and Sweden. In Canada, a 2004 conference on primary health care noted that there are problems when the terms *primary care* and *primary health care* are used interchangeably, since primary care is limited to health care service delivery and primary health care is a more expansive term that addresses health but also social issues (Lewis, 2004). Many definitions of primary health care appear to overlap significantly with health promotion. A difference may be in emphasis more than in approach or understandings of health or its determinants, although this has yet to be determined or debated in the health promotion literature.

Disability Postponement

Disability postponement has been described as "those intervention activities that focus on delaying physical or mental decline, service use or long-term care utilization among people who have an existing chronic illness" (Finlayson & Edwards, 1997, p. 457). Occupational therapists who work with people with preexisting conditions and disabilities might find the idea of disability postponement useful when considering opportunities to apply health promotion principles in practice.

Disease and Injury Prevention

Prevention is a concept that is closely linked to health promotion, especially when a behavioral approach to health is adopted. While most descriptions of prevention focus on disease prevention, occupational therapists might find it helpful also to consider injury prevention as a potential role (Finlayson & Edwards, 1997). Although there is sometimes significant overlap between health promotion and disease and injury prevention, prevention initiatives tend to be initiated in the health sector and focus on risk factors and behaviors that result in health problems.

Community Development and Capacity Building

Wilcock (1998, p. 238) describes community development as "community consultation, deliberation, and action to promote individual, family, and community-wide responsibility for self-sustaining development, health and well-being. It is a holistic, participatory model, aimed at facilitating a community's social and economic development, based on community analysis, use of local resources, and self-sustaining programs." Although some community development issues relate to health, community development is not limited to health; rather, it may result in initiatives that promote the economic development of a community. Community development initiatives are intended to expand the capacity of a community in terms of the knowledge and skills that are required for the community to survive and thrive.

In the case of community development, communities may be defined by the geographic location, but they are also defined by members with a common shared interest. For example, older adults in an amalgamating city might not live in the same neighborhood but come together as a community based on a common concern about how their voices will be heard in a new metropolitan area (Letts, 2003a). Communities can define themselves in a variety of ways. Bulmer (1987) notes that *community* is a normative as well as an analytic and descriptive concept and that communities are diverse and changing in how they are understood, making it important to describe the community that is the focus of any community development initiative.

Community development is at the basis of community-based rehabilitation (CBR), which emerged at about the same time as primary health care and is described as a community development strategy for rehabilitation (Kronenberg, Fransen, & Pollard, 2005). Through a recent position statement on CBR (World Federation of Occupational Therapists (WFOT), 2004) and other activities to gather information about occupational therapists' roles in CBR, WFOT has taken a lead role in demonstrating how community development can be used to promote community participation with people with disabilities around the world.

Not all health promotion initiatives fall within a community development framework. For example, individually focused initiatives that use a behavioral approach to health would not necessarily involve a participatory consultation process with community members to implement. However, many health promotion initiatives that occupational therapists describe do fall within a community development framework (Banks & Head, 2004; Letts et al., 1993; Wilcock, 1998).

HEALTH PROMOTION AND OCCUPATIONAL THERAPY

So how should occupational therapists take the broad body of knowledge and models of health promotion and apply them in their own practice? de Leeuw (1989) suggested that "health professionals should realize that their personal

involvement in health promotion should not mean they give up their disciplinary training and work area but rather that they should acquire some kind of framework of reference in which they could put their own efforts in the integrated, intersectoral health promotion context" (p. 103). In applying this quote to occupational therapy, Letts and colleagues (1993) suggested that rather than thinking about "doing" health promotion, occupational therapists should think about "doing" occupational therapy but within a health promotion framework.

Occupational therapists have applied health promotion frameworks, demonstrating a role for occupational therapists in varying contexts. Reitz (1992) documented ideas related to preventive health and wellness in the earliest foundations of occupational therapy. Wilcock (2001) documented the idea of the Regimen Sanitatis, which was influential from the twelfth to the nineteenth centuries. The Regimen includes a set of six rules for health that include such things as eating and drinking and getting adequate sleep. She demonstrates the link between these historical rules and the principles and strategies expressed in the Ottawa Charter (WHO, 1986) as well as occupational therapy's underlying premise of occupation for health, that is, that engagement in occupation is a prerequisite for health and also may have restorative benefits for people with health concerns.

Occupational therapy was founded on ideas related to promoting health and well-being through occupation, and a resurgence of discussions on the contributions that occupational therapists could make to prevention and health promotion began in the late 1960s (Reitz, 1992). In the next section, examples of occupational therapists using a health promotion framework are put into a conceptual context, and the challenges and opportunities of health promotion are considered.

Conceptual Links

The roots and underlying philosophy of client-centered occupation-based occupational therapy practice align well with the principles and models of health promotion. Thibeault and Hebert (1997) compared health promotion and occupational therapy principles, highlighting many areas of consistency in the approaches (see Table 18.2). For example, the participatory processes that are described as a principle of health promotion are very similar to the client-centered processes that occupational therapists have adopted for use with clients in a variety of settings. The links between social justice as a principle of health promotion and occupational justice and social justice that are valued by occupational therapists are also highlighted. Townsend (2003) has similarly focused attention on ideas of justice in client-centered occupational therapy practice. Both health promotion and occupational therapy practice have underlying principles related to respect for diversity in working with individuals and communities.

Community is one of the major foci of health promotion. Health promotion is implemented in partnership with a variety of communities and most frequently occurs within community contexts rather than within medical institutions. Initiatives that emphasize individual wellness often are undertaken in community contexts in order to reach the people who are the targets of the initiatives. Occupational therapy has a natural fit within community settings as well (Baum & Law, 1998; Scaffa, 2001). Thibeault and Hebert (1997) note that one difference between health promotion

---

TABLE 18.2   COMPARISON OF THE MAIN TENETS OF HEALTH PROMOTION AND OCCUPATIONAL THERAPY

Health Promotion	Occupational Therapy
Community participation	Worth of the individual with his or her unique nature, needs, potential, and growth, active within his or her own environment and community; occupation as the pivot of human life
Empowerment	Empowerment and enablement; occupational therapists, clients, and community members as equals
Social justice	Social justice
Greater autonomy for the community	Greater autonomy for the individual and the community
Importance of active and meaningful lifestyles	Importance of active and meaningful lifestyles; therapeutic dimension of occupation
Respect for cultural diversity	Respect for cultural diversity and marginalized groups

and occupational therapy is that health promotion is frequently focused on working with communities, while occupational therapy models tend to focus on individuals. They note that many models in occupational therapy are applicable with communities and groups but are seldom explicitly applied in that way. Occupational therapy practice in community settings is not necessarily grounded in health promotion principles or models. However, occupational therapists in community settings are well placed to challenge existing models of service delivery and work to share skills and knowledge using a health promotion framework.

Wilcock (1998, 2001) has provided a rich overview of the conceptual links between the underlying importance of occupation as a determinant of health and as a means to improve it, described as "occupation for health." Thibeault and Hebert (1997, p. 277) reinforce this by observing that occupation is viewed as the "pivot of human life" and note that occupational therapy considers the therapeutic dimension of occupation.

Occupational therapy's emphasis on client-centered occupation-based practice with increasing numbers of therapists in community settings means that occupational therapists are poised to apply their skills and knowledge within a health promotion framework. The sections that follow provide examples of occupational therapists who are involved in health promotion initiatives in different community contexts.

Practice Examples: Healthy Aging

Excellent examples that demonstrate the role of occupational therapists in promoting health when working with older adults are described in the literature. The Well Elderly Study in California demonstrated through a randomized clinical trial design that a preventive occupational therapy intervention (Lifestyle Redesign) resulted in benefits in health, function and quality of life (Clark et al., 1997), and these results were sustained after a six-month follow up (Clark et al., 2001). The nine-month occupational therapy intervention in the Well Elderly study focused on helping older adults to build positive changes into their lifestyles, covering areas such as transportation, safety, finances, and social relationships (Carlson, Clark, & Young, 1998). The processes that were used in the intervention included presentations of information to individuals and groups, peer exchange, and personal exploration. This same approach to intervention has been applied (with some modifications) in other settings, including a medical-model adult day program (Horowitz & Chang, 2004), and with middle- and upper-class older adults living in seniors' apartments (Matuska, Giles-Heinz, Flinn, Neighbor, & Bass-Haugen, 2003). The reports of applications to other populations have tended to be pilot studies, with small groups of older adults and no comparison or control groups. Despite the lack of rigor in the research designs, the studies do provide evidence that the Lifestyle Redesign

Program can be adapted and applied in a variety of contexts to promote health with older adults.

In the CAOT Seniors' Health Promotion Project (Letts et al., 1993), occupational therapists worked in seniors' organizations in two Canadian provinces (Manitoba and Newfoundland) to explore how occupational therapy skills and knowledge could be used in a health promotion framework. A diverse range of initiatives were undertaken, including a large initiative in Newfoundland to improve health through improved transportation for older adults in the city of St. John's and education sessions in Manitoba provided through cable television, print media, and presentations to seniors' organizations on senior-generated topics such as maintaining physical activity, home safety, and managing arthritis. Barnard and colleagues (2004) describe an initiative that was developed by occupational therapy faculty and students in partnership with older adults in a small North Carolina town. They developed a five-week wellness program focused on physical activity, using spirituality as a means of expression, increasing awareness of nutrition and cooking, and increasing cognitive functions. Miller and colleagues (2001) describe the Microwave Project, in which occupational therapy students worked with an interdisciplinary team and older adults who received Meals on Wheels to address a challenge that some recipients were having in reheating their meals adequately and safely. Older adults who were at risk of health problems because of difficulty with food preparation were involved in a luncheon program (if they were able to leave their homes to attend) or the homebound program so that they could gain skills in food preparation and reheating using a microwave oven (Figure 18.2). Community outreach was undertaken to give older adults with low incomes access to microwave ovens.

Additionally, numerous occupational therapists participate in falls prevention initiatives with older adults in the community (e.g., Clemson, et al., 2004; Tolley & Atwal, 2003). Overall, the occupational therapy literature suggests that there is a strong role for occupational therapy in adopting a health promotion framework with older adults. The initiatives range from those that take a behavioral and preventive approach (e.g., Lifestyle Redesign, falls prevention) to those that are more aligned with a socio-environmental approach to health (e.g., the CAOT Seniors' Health Promotion Project and the Microwave Project).

Practice Examples: Workplace Health Promotion

In 1986, a number of articles described the contribution of occupational therapy to workplace programs, including employee assistance programs (Maynard, 1986), health education programming to employees (Hollander Kaplan & Burch-Minakan, 1986), and workstation or office redesign (Allen, 1986). More recently, Moyers and Coleman (2004) identified strategies that occupational therapists

FIGURE 18.2   Older adult practices reheating coffee in microwave.

can implement in partnership with workers and employers to promote the health of aging workers, including job redesign, organizational restructuring, and health promotion initiatives that include wellness and physical activity programs as well as ergonomics, maintenance of abilities, and promoting ongoing interest in work. Kirsh, Cockburn, and Gewurtz (2004) describe roles for occupational therapists in promoting health in the workplace, including analyzing job demands and employer skills and designing workplace accommodations. Initiatives such as these are believed to promote healthy work and workers.

Although occupational therapists are among many professionals who are involved in workplace health promotion, the role of occupational therapy is not well established internationally. In one review of the effectiveness of workplace health promotion, occupational therapy was not an explicit component of any of the 35 multicomponent workplace health promotion programs that were reviewed (Heaney & Goetzel, 1997). Moreover, there seems to be limited rigorous evidence that demonstrates the effectiveness of occupational therapists using their skills and knowledge in this way. Occupational therapists need to demonstrate with rigorous data the effectiveness of contributions using a health promotion framework.

Challenges and Opportunities for Occupational Therapy in Health Promotion

Healthy aging and workplace health promotion are not the only health promotion initiatives in which occupational therapists are involved. Examples that are cited in the literature include partnerships with organizations that serve the needs of people with physical disabilities (Neufeld & Kniepmann, 2001) and a campaign to promote safe backpack selection and use for children (Jacobs, 2003) (Figure 18.3).

Another area of occupational therapy practice is mental health promotion (Creek, 2002). Although mental health promotion might not be a common area of occupational therapy practice in the United States, examples from other countries illustrate the contributions occupational therapists can make. For example, Russell and Lloyd (2004) describe an initiative in Australia that focused on physical and mental health promotion among people with mental illness. Each session included a physical activity component and didactic presentations on self-esteem and self-image, life skills, nutrition, relaxation, and stress management. Babiski, Sidle, and McColl (1996) described a health promotion role for occupational therapists and community support workers who provided support services to boarding home operators and tenants. The goal was to improve the tenants' quality of life by addressing individual, group, and environmental barriers to mental health. Olson, Heaney, and Soppas-Hoffman (1989) describe the role of an occupational therapist in a parent-child activity group, which was designed in collaboration between a teaching hospital and a local child care center to meet the needs of at-risk families. An occupational therapist and a counseling therapist developed and facilitated the activity group to help children to elicit positive attention from parents and to help parents respond effectively to the needs of the child. The group included discussion of parent-child activity interactions and facilitated play between the mothers and children.

Despite the potential and hope that such examples offer, occupational therapists who are interested in working from a health promotion framework face challenges. Occupational therapists frequently find themselves working in medical contexts, in which a socioenvironmental approach to health is not easily adopted. Further, many policies that are related to health promotion fall within behavioral and institutionally driven models of service delivery. Even community-based practices are often focused on short-term interventions with individual clients to address specific occupational performance concerns. Scriven and Atwal (2004) state that occupational therapy roles in health promotion most commonly involve tertiary health promotion (downstream work), facilitating individuals to develop personal skills to cope with disability or chronic illness. For occupational therapists who are interested in more community development approaches, it can be difficult to find support within existing models of service delivery (Spalding, 1996).

Funding for occupational therapy services from a health promotion framework is equally a challenge. When occupational therapy services are most frequently offered and billed on the basis of service provision to individual clients, it is challenging to link funding to working with communities on health issues in a participatory, empowering, intersectoral manner (Spalding, 1996). Related to funding is the availability of occupational therapy resources and how these are distributed to meet the health needs of

COMMENTARY ON THE EVIDENCE

Evaluating the Effectiveness of Occupational Therapy and Health Promotion

Establishing evidence to support the effectiveness of health promotion implemented by occupational therapists or anyone can be challenging in light of traditional approaches to research and evaluation and the underlying principles of health promotion.

Randomized controlled trials are frequently described as the most rigorous way to evaluate the effectiveness of interventions. However, they are best designed when the population receiving an intervention (and a control group) is well defined, the intervention is standardized, and the timelines for outcomes are reasonably short. In contrast, health promotion initiatives are often grounded in communities that have fluctuating memberships (making it very difficult to define intervention and control groups) and interventions that fluctuate depending on the responses of the community (making standardization of the intervention difficult) and may require significant lengths of time to result in change in community or individual health.

Furthermore, considering the principles underlying health promotion, there is a potential lack of fit between health promotion and traditional methods of evaluation. Lincoln (1992, p. S10) notes that "it does no good to improve the health of an individual if we simultaneously undermine her or his self-esteem and sense of agency" through research or evaluation. Traditional methods of evaluation may reinforce power imbalances that health promotion seeks to redress (Coombe, 1997).

Despite these challenges, it is important to demonstrate the effectiveness of health promotion. In health promotion evaluation, a randomized control trial might not always be the best approach to adopt. Gillies (1998, p. 114) notes that this design "simply cannot capture the richness of the process . . . they simply are not sufficiently sophisticated to deal with the complexity and diversity of the process and outcome of health promotion at community level [sic]."

As a result of the concerns about traditional evaluation methods, a number of sources have called for the adoption of participatory or empowerment evaluation (Green et al., 1995; Papineau & Kiely, 1996; Thibeault & Hebert, 1997; WHO European Working Group on Health Promotion Evaluation, 1998). In occupational therapy, participatory research has also been receiving increasing attention (Cockburn & Trentham, 2002; Letts, 2003b; Taylor, Braveman, & Hammel, 2004). Participatory evaluation involves participants in the evaluation throughout all stages, relies on the knowledge and expertise of all participants, and implements changes to the health promotion initiative resulting from the evaluation. These characteristics align well with principles of health promotion.

In all evaluations, the approach that is chosen needs to reflect the process that is being undertaken. Depending on the approach to health that is used in developing a health promotion initiative, a randomized controlled trial might be appropriate. For example, a randomized controlled trial can be useful in circumstances in which a well-defined intervention is offered to a distinct group of people, with a control group available. The Well Elderly Study (Clark et al, 1997, 2001) and falls prevention initiatives (e.g., Clemson et al, 2004) are examples of interventions that have been evaluated through randomized controlled trials. In other situations, a participatory, community, or capacity-building health promotion initiative might be better evaluated by using a participatory approach (Letts, 2003b; Taylor et al., 2004). Regardless of the type of evaluation, there is a need for occupational therapists who are involved in health promotion to plan evaluations of these initiatives to build a body of evidence to support the role of occupational therapy in health promotion.

---

communities. If more occupational therapy services are to be offered upstream, focused on primary health promotion with communities that are well and independent, would there be adequate therapy provision to meet the needs of people with disabilities (Scriven & Atwal, 2004)? There will almost undoubtedly always be a need for occupational therapists to provide services based on all three approaches to health: medical, behavioral and socioenvironmental. The challenge is to find the balance of resources that optimizes health and utilization of occupational therapy services.

Finally, if health promotion is to be valued as a role for occupational therapists, there needs to be more evidence

FIGURE 18.3   Students in Iceland model safe backpacks.

to support its adoption. The work of Clark and colleagues (1997) provides one example of an initiative to rigorously evaluate the effectiveness of occupational therapy in a prevention role with healthy older adults. Similar evidence is needed in other areas of occupational therapy practice. There are debates in the health promotion literature as to the best strategies to evaluate community-based health promotion initiatives (see Commentary on the Evidence). Regardless, systematic data gathering and analyses are needed to generate a body of evidence that supports the role of occupational therapy in health promotion.

Challenges can also be viewed as opportunities, and from those, strategies can be formulated to address them. If occupational therapists face challenges in using a health promotion framework, forming alliances with other groups is a useful strategy to consider. Other groups of health professionals may be allies in developing new roles in health promotion. For example, social workers, public health nurses, and community developers may be partners with occupational therapists. Working at the level of the multidisciplinary team is familiar to occupational therapists, and they have skills in optimizing health through partnerships (Spalding, 1996). Furthermore, community groups can be important allies in creating demand for occupational therapists to use their skills and knowledge in a health promotion framework (Fraser, Letts, & Carswell, 1993). Partnerships and alliances can be created at various levels. For example, individual occupational therapists can volunteer to work with a group of older adults at a community recreation center. At a broader level, professional organizations such as the American Occupational Therapy Association can partner with consumer groups, such as the American Association of Retired Persons to advocate for more occupational therapists working with well older adults to maintain and improve their health.

When applying occupational therapy skills and knowledge in a health promotion framework, occupational ther-

apists might also need to assess whether they have all of the necessary knowledge. For example, in consulting with communities and groups about their health issues, occupational therapists need to describe themselves in terms that focus on health rather than illness and disability (Letts et al., 1993). Further, occupational therapists need to understand the public policy process if they are involved in community organizing, coalition advocacy, or political action. For example, the AOTA developed a comprehensive advocacy initiative to remove Medicare caps on outpatient rehabilitation. The strategy involved the association as well as its members to advocate with the federal government and legislators to remove the caps. Any advocacy requires an understanding of what message needs to be conveyed, to whom, and how can it be delivered effectively. Finally, skills in program evaluation are needed to ensure that health promotion initiatives are evaluated.

CONCLUSIONS

Health promotion has evolved in recent decades, and this chapter has demonstrated congruence between health promotion and occupational therapy. Occupational therapists can apply their skills and knowledge using a health promotion framework, but they face a number of challenges to do so. It is important to begin by understanding approaches to health, health promotion, and related concepts such as population health, public health, community development, and primary health care. To develop partnerships in health promotion, occupational therapists need to be able to describe occupational therapy in a way that focuses on health rather than disability. Occupational therapists need to work with individuals, groups, and communities to identify the health issues that need to be addressed. Funding for occupational therapists to work from a health promotion framework continues to be a challenge and may require creativity and searching for funding outside of traditional sources. For example, foundations that are interested in community organizing might fund an occupational therapist in a coordinating function. Finally, as work in the area of health promotion increases, rigorous evaluations need to demonstrate the effectiveness of occupational therapy in health promotion.

PROVOCATIVE QUESTIONS

1. "Unless professionals think simultaneously in both personal and structural ways, they risk losing sight of the simultaneous reality of both. If they focus only on the individual, and only on crisis management or service delivery, they risk privatizing by rendering personal the social and economic underpinnings to poverty and powerlessness. If they only focus on the structural issues, they risk ignoring the immediate pains and personal woundings of the powerless and

people in crisis" (Labonte, 1994, p. 259). What does this quote say to you about the role of occupational therapy in health promotion? Consider examples in which occupational therapists might be overemphasizing individual or structural issues and how a balance between the two can be maintained.

2. Examples of health promotion in occupational therapy often seem to be grounded in a behavioral approach to health. Critics of the behavioral approach note that this approach, more than either a medical or a socioenvironmental approach, is at risk of blaming the victim. For example, suppose a person becomes injured because he or she used an improper lifting technique even after receiving education on proper lifting techniques from an occupational therapist. Furthermore, despite receiving information about the importance of abdominal exercise and general fitness to prevent back injuries, suppose the person chose a more sedentary lifestyle with limited physical fitness activities. When the person is injured at work, it might result in a conclusion that the injured worker is to blame for the injury and a belief that the person deserves less compensation or rehabilitation because he or she should have known better. Do you agree that the injured worker is to blame? How does this affect your perception of the person in general and as an occupational therapist?

Community Integration

BRIAN J. DUDGEON

19

Learning Objectives

After reading this chapter, you will be able to:

1. Define disability and identify challenges to participation that those with disability are likely to experience as part of community living.
2. Contrast client-centered and community-centered approaches to practice.
3. Distinguish between clinical service and advocacy roles regarding community integration.
4. Discuss approaches to community-centered assessment and identify coalitions that may be formed as part of advocacy for access and acceptance.

INTRODUCTION

To design goals and interventions that promote participation in communities, it is important to consider concerns for specific individuals as well as needs of the entire community. In promoting participation, both client- and community-centered approaches are used. These approaches have common issues and goals but have distinct intervention strategies. This chapter presents the continuum of client-centered and community-centered interventions to facilitate participation for people with disability.

On an individual basis, intervention may focus on community integration of a child with disability or reintegration of an adult with onset of disability. This client-centered approach emphasizes developing, restoring, or adapting the individual's skills as well as organizing and using assistance available in natural supports from family and friends (Law & Mills, 1998). It also includes the creation of accessible environments that promote the individual's membership, belonging, and sense of having a constructive role.

On a population or community basis, intervention emphasizes accessibility and acceptance within physical, social, and cultural environments. **Community-centered** approaches generally involve advocacy, creating universal or accessible design throughout the community, and the promotion of understanding and inclusion of those with differing characteristics or abilities.

PARTICIPATION IN COMMUNITY: DEFINITIONS

Difficulty in carrying out activities is regarded as **disability**, and various impairments of body systems can contribute to one's inability to carry out activities in an expected or accepted manner. While many activities are private, disability is also associated with problems in **participation**, or an individual's involvement in life situations in communities. Activity limitation as well as environmental barriers may contribute to restrictions in participation. Environmental factors include the physical, social, and attitudinal settings in which people live and conduct their lives (World Health Organization, 2001).

Community reintegration has been formally defined as the process of becoming part of the mainstream of family and community life, participating in normal roles and responsibilities, and being an active and contributing member of one's social groups and society as a whole (Dijkers, 1998). Moves toward focusing on participation rather than integration are now acknowledged (Brown et al., 2004). The community integration construct has been called into question through examination of clinical and research measures (Minnes et al., 2004), and similar dilemmas are seen with multidimensional aspects of participation as part of community living (Dumont, Bertrand, Fougeyrollas, & Gervais, 2003). Whereas integration denotes membership, participation implies sharing as an active and dynamic process, and this description might better characterize views of individuals with disability.

Contexts termed *community* have been debated as well. Definitions of **community** include a people's sharing of an area (e.g., locality, district, government) as well as interests and interactions and perhaps a sense of shared identity (Oxford English Dictionary, 2001). Community is also defined by the designation of rural, suburban, and urban communities, which is based on metropolitan statistical area or measurements of population density. These designations are sometimes used to contrast communities in terms of resource availability as well as lifestyles and diversity (Fazio, 2001).

Traditional views of community are helpful in conceptualizing both the needs of individuals as well as groups within the community. Toennies (translated in 1957) used the German term **gemeinschaft** to characterize the relationships between individuals that are private and based on shared interests with kin or family, neighborhoods and groups of friends. Such personalized community elements were contrasted with **gesellschaft**, the term used to characterize system resources and actions that are a public expression or response to a duty or to an organization within society. While both *gemeinschaft* and *gesellschaft* are present in contemporary societies, urban settings are often viewed as having fewer personalized supports in place and rural settings as having fewer system resources

(Christenson, 1979). The rural versus urban, personal versus system contrasts might be overly simplistic, particularly in modern times as intentional or virtual communities form based on shared interests and identity, with connections that are electronic and not dependent on shared geography (Fellowship for Intentional Community, 1996; Rheingold, 1998). For some, participation through the Internet can make disability invisible, along with other aspects of identity (Bowker & Tuffin, 2002).

Nevertheless, these definitions of community remind practitioners to draw on natural helpers and supports in the environment while also informing clients about their rights, responsibilities, and entitlements to participate within community programs and systems. Uses of natural helpers and supports are hallmarks of community integration and can play a key role in assessment and intervention planning (Hagner, Rogan, & Murphy, 1992; Israel, 1985).

Another useful characterization of community is found in Bronfenbrenner's model (1977), which recognizes the interdependencies that exist between people and their social settings. According to Bronfenbrenner, the individual lives in a microsystem, the immediate settings involving factors of place, time, physical features, activity, participants, and roles. Interrelations between microsystems such as home, school, and workplaces are designated a mesosystem and include personal groupings such as family and friends, schoolmates, and coworkers. Formal and informal social systems at the local level are termed exosystems and include influences of neighborhood, mass media, agencies of government, business, communication and transportation systems, and other social networks. At the societal level is the macrosystem, the overarching patterns of the culture or subculture that often guide or organize the economy as well as educational, social, legal, and political systems.

The complex interdependence between individuals and their environmental surroundings is important for understanding issues and developing interventions that include all levels of community. Client-centered approaches focus on microsystems (e.g., the home), and community-based approaches include mesosystems as well (e.g., local stores, school, work settings). Community-centered approaches are focused on exosystems (e.g., public health programs) and macrosystems (e.g., public policy, rules and regulations) that may optimize accessibility and acceptance within communities. An individual's success with transition toward community participation will likely involve change at both the individual and community levels and points to a necessary blending of client-centered and community-centered approaches.

The term *community (re)integration* suggests that a poor fit exists between the individual and the community in which he or she seeks a connection. The individual might feel different, excluded, and perhaps not welcome. Therapeutic and social efforts seek to afford individuals a right to become a participating member within a community and give guidance in understanding responsibilities and duties

FIGURE 19.1   A customer shops with his wife and pays for groceries at a local market for vegetable growers. Both accessibility and acceptance are a part of community participation. Photo by Jackie Hall, M.S., OTR, VA Puget Sound Health Care System.

to the community. When these efforts are successful, full participation allows unrestricted and equal association, access, and acceptance into a community (Figure 19.1). Inclusion may be used to describe one's presence in a group or an opportunity to fully participate. With a strong understanding of person-environment interactions, occupational therapy practitioners are well prepared to promote community integration (Collins, 1996).

For occupational therapists and other practitioners, tension exists between scope of practice and context of practice. We have seen moves from institutional care to center-based care to community-based care. Institutional care, now generally frowned on, began as a thoughtful strategy to congregate and protect people who were perceived as being vulnerable. However, protection resulted more in segregation, alienation, and stigmatization (Priestly, 1999). Moves toward deinstitutionalization lead to center-based care, in which buildings were created for purposes of congregating services, with an effort made to have centers considered a part of the regional or local community. Dissatisfaction still exists with centers, due to perceived disconnection with natural contexts. So now a **community-based** orientation is promoted with a focus on actual environments of function and participation (e.g., homes, schools, businesses, parks, and transportation) (Law & Mills, 1998; McColl, 1998). Advocacy for community-based rehabilitation is also part of the World Health Organization's mission in promoting inclusion and opportunities for people with disability worldwide (WHO, 2004).

Client-centered and family-centered approaches can be community-based (Scaffa, 2001) but are distinct from community-centered approaches, in which community systems, places, or attitudes are addressed. These approaches have specific focuses of concern and different evaluation and intervention practices.

Client-Centered Approaches

Concern for the individual's community participation typically involves analysis of personal environments such as home accessibility, safety, supervision needs, and personal as well as social engagements. Reorganization of such environments, additions of durable medical equipment, and architectural modifications are sometimes necessary, as are family training and counseling regarding provision of assistance. **Client-centered** or family-centered approaches may include accessing, advising, and/or training to support performance in local community settings such as the grocery store, movie theater, park, and community bus or rail system. Sometimes attention is focused specifically on performance and participation in educational programs, volunteer or paid work settings, or involvement with organized city or county recreational facilities and programs. Citizenship activities such as access to voting also may be addressed.

The individual's and family's means of making changes in the home, communication systems, means of transportation, and returning or new participation in community activity is planned with and around the client and his or her resources. Values that are supported in that effort are client-specific and culturally sensitive. For some people, independence and a reduced burden of care and/or economic burden on one's personal network (e.g., family) are priorities. Sometimes the choices and ultimate decisions made by clients and families might differ from the practitioner's recommendations, but in client-centered care, the client's authority and preferences are supported by the practitioner's teaching and guidance rather than the practitioner's directing or commanding (Scaffa, 2001). The practitioner uses a non-directive style and a phenomenological approach in having individuals describe their experiences and their reality (Law & Mills, 1998). Respect for client and families and making sure that enough time is devoted to active listening are essential components of a client-centered approach. Self-efficacy is also at the core of client-centered practice (Baum, 1998), but clients and families will differ in how much they want to participate in a partnership. Regardless, being treated with respect and receiving information that will help in decision making is likely to increase client and family satisfaction.

Community-Centered Approaches

Concern about integration of all community members with disability calls for different orientations and intervention strategies. Community-focused strategies are discussed, but for understanding needs and setting priorities, it is helpful to review the community participation chal-

lenges that people with disability experience. A recent survey reports that nearly 49 million people (19% of the U.S. population) have a disability or limitation in one or more activities of daily living (ADL) or instrumental activities of daily living (IADL) (Kraus, Stoddard, & Gilmartin, 1996). Over 12% of the U.S. population has what is regarded as a severe disability, and almost 4% need personal assistance during their daily lives. IADL problems are more common than are ADL difficulties for people with disability, and adults with IADL problems are most often challenged by problems of mobility, cognition, manipulation, and activities involving vision, hearing, and communication. Another common characteristic of people in the community with disability is unemployment. For many groups with disability, the community wide rate of unemployment is well over 60%, and the poverty rate for people ages 25 to 64 years with severe disability is nearly 28%, compared to 8% for those without disability. Although older age and residence in a rural setting are indicative of greater rates and severity of disability, the prevalence of disability and needs for addressing health challenges appear to be on the increase in all age groups (Lollar, 2002; Rimmer & Braddock, 2002).

A move from a client-centered to a community-centered focus on health and well-being brings attention to the reality that while health is a personal issue, one's health status and functional well-being involve a dynamic interaction between personal factors and community factors. The latter can be explored through addressing the **independent living movement (ILM)** practices of public health and other efforts to create safe, healthy, and accessible communities that enable full participation.

Independent Living Movement

During the latter half of the twentieth century, as larger numbers of individuals with disability sought opportunities within communities, the ILM was created and gave rise to a number of public changes in views about disability (DeJong, 1979). For example, the Americans with Disabilities Act of 1990 brought a sense of civil rights to all communities, an extension of the rights that had previously been associated only with government programs (e.g., Rehabilitation Act of 1973, Education for All legislation [PL 94-142] of 1975). The ILM is a social movement that was conceived and aimed toward a better quality of life for people with disability. The ILM is heavily indebted to other contemporary social movements such as civil rights, consumerism, self-help, demedicalization of self-care, and deinstitutionalization. The self-empowerment of people with disability is credited with a shifting of traditional policy values to integrated living values. Examples include shifts from concepts of care to participation, from segregation to integration, from normalization to self-determination, from charity to civil

rights, and from caseload to citizenship (Priestly, 1999). The ILM recognizes the following:

> Each person has the right to independence through maximum control over his or her life, based on an ability and opportunity to make choices in performing everyday activities. These activities include: managing one's personal life; participating in community life; fulfilling social roles, such as marriage, parenthood, employment, and citizenship; sustaining self-determination; and minimizing physical or psychological dependence on others. Community integration incorporates ideas of both place and participation, so that a person is physically located in a community setting, and participates in community activities. Issues of consumer direction and control also are integral to concepts of community integration. (National Center for the Dissemination of Rehabilitation Research, 2006)

The ILM continues to be a social force that acknowledges changing community systems. For example, during the rise in health care costs nationwide, people with disability are put at particular risk. Medical expenditure per capita for people reporting two or more disabling chronic conditions can be five times the amount incurred by those with no limiting conditions and almost two times the amount incurred by those with one limiting condition (Rice & LaPlante, 1992). Those with disabilities caused by chronic conditions have higher-than-average health care costs and are considered a high-risk population that calls for rehabilitation specialists to partner with consumers to effectively advocate for services (Batavia, 1999). Moves toward managed care have put a squeeze on individuals and groups of people with disability, which results in Medicaid (i.e., publicly funded health insurance) being the single largest provider of health care financing for people with disability (DeJong, Palsbo, Beatty, Jones, Kroll, & Neri, 2002).

Public Health Perspective

Financial dilemmas associated with health care costs and particular challenges associated with disability draw attention to another important community orientation. A **public health** perspective recognizes the value of medical care as only one level of intervention, bringing attention to prevention of community-wide health challenges. In public health, the **target condition** is the health or disease outcome that the preventive care intervention avoids (primary prevention), identifies early (secondary prevention), or treats effectively (tertiary prevention). **Risk factors** are the attributes associated with the target condition and may include demographic variables, behavioral risk factors, and environmental factors. The most promising role for prevention in current practice may lie in changing the personal health behaviors of individuals prior to disease

or injury onset. For example, about half of all disability and deaths may be attributed to tobacco, alcohol, and illicit drug use; diet and activity patterns; motor vehicles; and sexual behavior. Prevention practice can involve all health and education professionals (U.S. Preventive Services Task Force, 1996).

Although public health practices are found in various agencies outside of hospitals or other health care settings, important roles for all practitioners are acknowledged. Physicians, for example, are encouraged to provide brief advice during routine visits and to refer clients to allied health professionals with special counseling skills in their areas of expertise (e.g., occupational therapy for automobile driver safety). For all practitioners, principles of prevention follow along with ideas of patient activation (Hibbard, 2003) and include those in Box 19.1.

Every opportunity should be taken to deliver preventive services, especially to people who have limited access to care. Delivering preventive services at every visit is recommended. For some health problems, community-level interventions might be more effective than clinical preventive services. An important role for clinicians is their participation in community systems that address various types of health problems.

Public health practices are often described by using the analogy of a continuous flowing river (Orleans, Gruman, Ulmer, Emont, & Hollendonner, 1999). Downstream tactics or programs seek to make a change in individual behaviors of people in targeted groups that are at risk and sometimes all groups within communities. Midstream strategies are designed to influence those who might have an influence on individuals. Physicians and other health practitioners as well as educators may be recruited to deliver prevention practice information. Upstream concerns confront public policy and regulatory mechanisms that have a population focus. Examples include pollution and other environmental issues as well as roadway safety and manufacturing of devices for public use.

Healthy People 2010

Within the United States, public health strategies are a part of the development of national health priorities. Sponsored by the U.S. Surgeon General and building from previous national health priorities, Healthy People 2010 identifies 10 public health priorities for the country (Office of Disease Prevention and Health Promotion, 2001). Health People 2010 seeks to augment the health of each individual, the health of communities, and the health of the nation. The report serves as a basis for developing community plans to address two paramount goals for individuals of all ages: (1) Increase quality and years of healthy life, and (2) eliminate health disparities that exist within the population. Stark differences in health exist on the basis of gender, race or ethnicity, education or income, disability, geographic location, and sexual orientation. Ten health indicators are designated to serve as targets for individual and community action, and focus areas call for specific attention to key activities to reduce or eliminate illness, disability, and premature death among individuals within communities (Box 19.2).

Health promotion and disease prevention activities have long been advocated within occupational therapy, and Healthy People 2010 calls for community-centered application of those ideals (Hildenbrand & Froehlich, 2002). Areas of focus can become widespread and include efforts to promote uses of assistive technology, accessible design, and access to health-promoting occupations for all people. While different from traditional client-centered services,

---

BOX 19.1   ACTIVATION PRINCIPLES

- ◆ Assisting individuals to assume greater responsibility for their own health and personal health practices.
- ◆ Seeing individuals as the principal agents in primary prevention and empowering and counseling individuals to change health-related behaviors.
- ◆ Understanding that when people have the confidence to affect their health, they are more likely to do so than are those without such confidence (Schwarzer, 1992).
- ◆ Shared decision making and respect for values about possible outcomes.
- ◆ Education and consideration of choices, preferences, and uncertainty as part of decision making rather than a uniform policy for all people.

BOX 19.2   PUBLIC HEALTH CHALLENGE TARGETS

- ◆ Promote regular physical activity.
- ◆ Promote healthier weight and good nutrition.
- ◆ Prevent and reduce tobacco use.
- ◆ Prevent and reduce substance abuse.
- ◆ Promote responsible sexual behavior.
- ◆ Promote mental health and well-being.
- ◆ Promote safety and reduce violence.
- ◆ Promote healthy environments.
- ◆ Prevent infectious disease through immunization.
- ◆ Increase access to high-quality health care.

many efforts that address community-centered concerns can be approached though cost-effective collaborations (Merryman, 2002).

National organizations, such as the American Occupational Therapy Association, are called on to develop programs that empower individuals to make informed health care decisions and promote community-wide safety, education, and access to health care (e.g., backpack safety for school-aged children) (American Occupational Therapy Association, 2005). Primary prevention is a priority for community action. To address Healthy People 2010 objectives, arenas for programmatic interventions include places where people congregate and interact. These may include school settings, worksite settings, health care settings, and the community at large through public facilities, local government agencies, and social services as well as faith-based and civic organizations to reach people where they live, work, and play.

EVALUATION AND INTERVENTION TO ENABLE COMMUNITY PARTICIPATION

Evaluation and intervention services can be provided on a continuum using both client-centered and community-centered perspectives. Intervention initially may focus on the individual and a shift from institution or clinical context of care to the client's own community. This shift moves intervention to natural environments in which clients conduct their lives and encounter and adapt to realities of physical, social, and political contexts. At the other end of the continuum, intervention may focus primarily on the community, where one takes action to change community systems to enable full participation by all individuals, including those with disability (Figure 19.2).

Client-Centered Evaluation and Intervention

Evaluation of the individual includes a traditional approach of addressing the client's skills and needs but also includes people who are in the client's personal network (e.g., family, friends, and neighbors). An individual's place of residence and local settings in the community and transportation systems are also assessed.

Assessment of participation can focus on a single care recipient or on a sampling of individuals with specific diagnostic conditions or classifications of disability. While the International Classification of Functioning, Disability and Health (ICF) model directs that greater attention be given to participation as an outcome, the effective measurement of participation is viewed as problematic and in need of new assessment approaches (Granlund, Eriksson, & Ylven, 2004; Jette & Haley, 2005; Okochi, Utsunomiya & Takahashi, 2005; Salter, Jutai, Teasell, Foley, Bitensky, & Bayley, 2005). Although a variety of measures have been

proposed to evaluate community integration and participation, critiques of those measures reveals that it is often difficult to measure activity and participation levels separately (Perenboom & Chorus, 2003). Approaches to community participation assessment do indicate that the phenomenon is best addressed as a self-reported outcome. How the individual views his or her level of success and the individual's identification of barriers with participation are important features of assessment.

Shifting from a center-based to community-based approach requires shifting practice environments as well as shifting one's philosophy. Practitioners must be expert in consultation and program development and focus on issues that are broader than typical direct service (Dudgeon & Greenberg, 1998). Working through teachers in schools, supervisors in jobs, and other natural supports in the community might be necessary to be effective. In transitioning to community-based practice, Fazio (2001) suggests that natural settings might be the most effective arena for service delivery. Community-based approaches, such as evaluating people's needs in their homes, are encouraged (Freeman, 1997; Sabari, Meisler, & Silver, 2000) and are sometimes found to be effective for stroke rehabilitation and for individuals with brain injury (Anderson et al., 2000; Willer, Button, & Rempel, 1999).

Community-Centered Evaluation and Involvement

Community assessment may involve exploration of incidence and prevalence of occupational dysfunction needs within populations. However, assessing dysfunction could

backfire and not support a community because it focuses on deficiency rather than potential. Kretzmann and McKnight (1993) suggest that we need to move away from focusing on community deficiencies (e.g., unemployment, crime, illiteracy, gangs, and dropouts). Instead, moves can be made toward recognizing and utilizing relationships between community assets such as those that exist in individuals (e.g., the elderly, youth, artists), citizen organizations (e.g., cultural groups, churches), and local institutions (e.g., schools, businesses, parks, hospitals). A "needs survey" becomes a deficiency inventory, whereas a "capacity inventory" moves toward empowerment of communities (Kretzmann & McNight, 1993). McKnight (1994) argues that health care organizations can behave as community members (e.g., through advocacy, financing, volunteerism, and space availability) and address community needs by focusing not on an epidemiological or diagnostic ideology but on an individual, family, or community's capacities and assets.

Kretzmann (2000) contends that health is a product of four determinants: (1) the behavior of the individual, (2) the strength of individual social relationships, (3) the healthfulness of the physical environment, and (4) the economic status of the individual. He proposes "asset-based community assessment and development." Skills of local residents, power of voluntary citizens' associations, and resources of public, private and nonprofit institutions should be harnessed to promote health within a community. For example, to address the influence of local associations, practitioners might explore partnerships with schools, youth organizations, local businesses, and associations that promote participation by those with disability. Such partnerships might include collaborations with Coalitions of Citizens with Disability, the National Alliance for the Mentally Ill, ARC (the national organization of and for people with mental retardation and related developmental disabilities and their families), the Arthritis Foundation, or other support and advocacy organizations.

Occupational therapy practitioners have much to contribute to community accessibility and acceptance of people with disabilities. Contributions may involve developing community partnerships with a "new cadre of colleagues including people with disabilities, engineers, architects, personal assistants, independent living counselors, recreation and exercise personnel, city planners, law enforcement, and transportation specialists" (Baum & Law, 1997, p. 280). Community change can be approached through county and city councils, business and visitor bureaus, and local media and advocacy organizations.

Advocacy About Accessibility

Advocacy, a key element of community-centered care, brings attention to issues and educates potential members of a community, ultimately drawing them into problem-solving actions that may resolve or lessen barriers to participation. At the community level, advocacy may focus on accessibility and acceptance. Community accessibility involves the application of accessible design rules that have been established over the years at the federal, state, and local levels through building codes. In both new construction and remodeling, accessibility guidelines help to create access for those who are challenged in the areas of mobility, cognition, manipulation, hearing, vision, and/or communication. Access applies to the building environment as well as to products and other community systems such as transportation, communication, and information systems. For example, for people with any combination of sensory, motor, or cognitive difficulties, access to the Internet is challenged by Web designs that restrict accessibility options and may restrict individuals' access to information and participation in virtual communities (World Wide Web Consortium, 2001).

Although accessibility guidelines have been in place for several decades, some dissatisfaction continues to exist with design because codes dictate a minimal approach to access rather than a universal application of design that may apply to a more inclusive community. **Universal design** concepts and principles suggest that environments and products be designed to be usable by all people, to the greatest extent possible, without the need for special arrangements, adaptations, or greater cost (Center for Universal Design, 1997; Iwarsson & Stahl, 2003).

Accessible and universal design needs to have advocates in the community. While many people with disability do advocate on behalf of themselves and others, greater community awareness and improved timing of attention to accessibility need to occur. Both design and manufacturing of buildings and other systems are expensive ventures, and a lack of attention to access or universal design becomes cost prohibitive if applied too late. As an advocate, one needs to practice what one preaches. Such an attitude may include doing business with those who provide access and boycotting those who fail to address accessibility. One can also apply accessibility and universal design to one's own environment. In recent years, the concept of **visitability** has been suggested and sometimes mandated (Smith, 2003). Visitability applies simple design elements to residential settings. The concept and practice creates at least one level entrance to a dwelling and access (e.g., 32 inches wide) to one bathroom on that level. Other suggestions for universal design in homes are the creation of floor space for toilet and tub transfers as well as structural supports in walls for the mounting of grab bars that might become necessary for safety and independence. A shortage of accessible living settings in neighborhoods is a recognized problem, and creation of visitability might help to overcome such shortages.

Advocacy About Acceptance

Addressing community acceptance of people with disability can be a harder advocacy role to assume. The "differentness" that disability entails often creates mystery and

uneasiness. Comfort within a community is sometimes based on similarity rather than on differentness (Whyte & Ingstad, 1995). A more accessible environment could provide people with disability a greater feeling of acceptance, but disability also can evoke feelings of blame, shame, pity, and avoidance. Physical, cognitive, sensory, and behavioral differences might need to be addressed by educating for understanding and the practice of inclusion in residential, educational, employment, and recreational settings. One of the hallmarks of community-based rehabilitation is the recognition that barriers to full participation exist in the community and that one can increase community awareness of the needs of members with disability, providing changes that create occupational opportunities (Baker & Brownson, 1999). Access to opportunities for citizenship, housing, employment, transportation, education, and other social structures give people with disabilities opportunities to be successful. Occupational therapy practitioners can support the initiatives of people with disabilities or advocacy groups that promote social development and lead toward institutional, political, and social frameworks that support full participation. For example, practitioners could hold forums to educate employers in the local community about the workplace accommodations that are most useful to people with psychiatric disabilities. Unlike a physical accommodation such as a wheelchair ramp, accommodations for people with psychiatric disabilities are often social in nature and need ongoing attention and retraining.

CASE STUDY: *Jason's Story: Living with a Spinal Cord Injury*

Jason is a young man who experienced C-6 complete spinal cord injury one and a half years ago in a motor vehicle crash. As a 23-year-old, Jason had completed high school and had worked in various entry-level service jobs before his injury. With nearly complete loss of sensation and movement from C-7 down, his medical rehabilitation involved development of wheelchair mobility skills and adapted performance of activities of daily living, including self-catheterization and a bowel program. Jason was also instructed to do regular skin inspection, follow diet and weight control measures, and engage in fitness activities.

To address independent living and community integration as part of discharge planning, the Craig Handicap Assessment and Reporting Tool (CHART) (Whiteneck, Charlifue, Gerhart, Overholser, & Richardson, 1992) was used as part of assessment and intervention planning. Jason scored well on all mobility items but had lower than expected scores related to occupation, economic, and social outcomes. As part of care planning, therapists were involved in doing a home assessment, staging of independent living trials within the hospital, and going out with Jason and others on various community outings to explore transportation and community functioning.

Jason would be discharged to apartment living in a building his family owned, which his sister-in-law lived in and managed. He would have reduced rent, and both his sister-in-law and his brother would be nearby to provide assistance as needed.

Within the hospital setting, a trial apartment-style unit was available for Jason to stay in and practice routine living activities toward the conclusion of his stay, with nursing and therapy services readily available as necessary. Community outings were coordinated through recreational therapy and occupational therapy. These included shopping at a grocery store as part of a meal preparation and cooking activity, viewing a movie at a local theater, and shopping for clothes in a department store. Orientation to city bus services was provided, and Jason was encouraged to use the bus, with the plan that he would later be referred for driver's training. Jason also works with vocational rehabilitation and is planning to enroll in college to enhance his potential for employment that would require fewer physical demands.

Jason's experiences were reflected best by his later return for outpatient therapy and interview by his therapist, who asked about community functioning.

Regarding his transition, Jason said, "I mean it's such night and day between when I got discharged from the hospital and now as to how fast I can do things. It just frees up so much time. I mean, it's amazing how much more free time I have, and time to concentrate on living life rather than getting through life. I mean, taking care of myself used to be all of my day right there. And now I can be at home and maybe get something to eat and get a second wind again, and go out with friends or something, but it's definitely a large stamina issue." Jason went on to say, "I really enjoy the company of my friends, but I can't hang out with them for more than a couple of days at a time because they'll run me dry. I mean . . . I'll start getting haggard and tired and falling asleep sitting in my wheelchair."

Reflecting on his inpatient rehabilitation, Jason was positive about "the support group that was there, the therapy, the people coming in the middle of the day to try and get you up and get you about. I mean those early stages are pretty important. Without that, it's easy to just stay down and not really have a desire to get better and strive for more." Jason said, "It definitely, sort of feels like I've been taken under wing by a community. I definitely could not have done what I have . . . without that support."

Jason described rehabilitation as "just learning all over again . . . something that you unconsciously learn when

> **CASE STUDY:** *Jason's Story: Living with a Spinal Cord Injury*   *Continued*
>
> you are a toddler." Jason mentioned the importance of exposure to various pieces of equipment and learning how to use adaptive devices. He remarked, "It definitely can be huge in someone's life, and so I think it's good and important to have those things shown to you."
>
> About his discharge, he said, "It feels like you're getting tossed out somewhere. I mean, I definitely knew they weren't just saying bye; I knew I was still going to be signing up for out patient therapy. Yet at the same time, you do kind of feel like you're definitely tossed out on your own."
>

>
> Jason reported that he "definitely has more of a feeling of . . . unconditional love" and that the compassion he had been shown had made him "see a more loving side to the world." He also reported feeling "more at peace" with himself, but he continued to be challenged with being different. About being in the community, Jason said, "It's the last place I want to be, like, I'm this kid in a wheelchair in a sports athletic store, and it's just so frustrating. I just want to hide from everybody. It's just working on trying to be comfortable with myself again."

SUMMARY

Community well-being is both behavioral and social in nature and includes individual lifestyle behaviors, the environment, socioeconomic factors, and local, state, and federal regulations and policies. Promoting participation in community life includes client and community approaches. One way to conceive of community care is to apply a public health model, with practitioners providing midstream and upstream interventions. Primary prevention measures are those that prevent the onset of a targeted condition (e.g., antismoking, promotion of activity and fitness). Such practices may be advocated and taught in community centers, senior programs, schools, and workplaces. Secondary prevention measures identify and treat asymptomatic people who have developed risk factors or preclinical disease before the condition is clinically evident. Examples include backpack safety for school children, ergonomics for at-risk workers, fall prevention among the elderly, and violence prevention in various settings. Tertiary prevention measures focus on intervention with people with clinical illnesses, health conditions, and disaster relief needs. Traditionally, occupational therapy practitioners focused on development, recovery, or adaptation as well as prevention of secondary complications, and maintenance of skills in community living. More recently, practitioners are shifting their focus to include community-centered intervention approaches to promote participation for all people, regardless of their ability status.

PROVOCATIVE QUESTIONS

The International Classification of Function and Disability places an emphasis on participation as an important characteristic in measurement of health. *Participation* is defined as "involvement in a life situation," and *participation restrictions* are defined as "problems an individual may have with involvement in life situations." Some prob-

lems can be due to environmental factors, which include all aspects of the physical, social, and attitudinal world.

Although defined, the measurement of participation is more challenging and is the subject of some controversy. Brown and colleagues (2004) have suggested that *community integration,* a construct that first emerged as part of deinstitutionalization of people with developmental and mental health disabilities, be replaced by or amended with the term *community participation. Community integration* may be viewed as a term that outsiders use in describing successful or unsuccessful fitting in to community living. In contrast, *community participation* can suggest a more dynamic status as part of community living.

1. Have you, a family member, or a friend experienced a difference or disability that caused a problem with participation? What was the nature of that problem, and in what ways could have participation been enhanced?
2. Ask that same question using the term *integration.* Have you, a family member, or a friend experienced a difference or disability that caused a problem with integration? What was the nature of that problem, and in what ways might integration have been enhanced?
3. The terminology above in some ways reflects a tension between the medical model and the social model of disability. In the medical model, disability reflects a deficit in the person who is unable to lead life in traditional or accepted ways. In the social model, fault for dysfunction is shifted to society, wherein systems and environments are viewed as enabling or disabling, such as creating barriers to performance and effective participation. Occupational therapists may appraise environments as being enabling or disabling, yet there is continuing tension between devoting resources to "fixing the person" and devoting them to "fixing the environment." For example, accessible and universal design are promoted as a means to create more enabling environments for everyone, yet the

expenses of retrofitting the existing built environment and designing with universal design ideas from the start are often viewed as excessively costly and unachievable. After its passage, the ADA was soon regarded as one of the U.S. government's largest *unfunded mandates.* What are your thoughts (and conflicts) relative to fixing the community to enable better participation, versus fixing the person or enabling the person to deal better with participation challenges in unaltered communities?

Occupational Justice

ANN A. WILCOCK AND
ELIZABETH A. TOWNSEND

Learning Objectives

After reading this chapter, you will be able to:

1. Describe occupational justice.
2. Describe the integration of occupational justice within occupational therapy.
3. Identify occupational injustices with regard to clients.
4. Discuss approaches to advocate and mediate for change to enable clients to participate in occupations according to their needs.

Occupational justice is an integral but only recently acknowledged aspect of occupational therapy. From the profession's beginnings, therapists based their interventions on the idea that occupations contribute to health and that people have both a need and a right to participate in meaningful occupations (Dunton, 1915; LeVesconte, 1935; Meyer, 1922; Wilcock, 1998). To illustrate the power and potential of occupational justice, three intervention scenarios using an occupational justice perspective are presented.

The concept of occupational justice gives voice to occupational therapists' implicit historical and ethical stance to address potential or real injustices (Wood, Hooper, & Womack, 2005). In the mid-1990s, the concept of occupational justice arose from two directions of study in two different parts of the globe. One direction, concerned with understanding the relationship between occupation and health, discovered that beneficial or negative health outcomes related to occupations are dependent on sociopolitical and cultural determinants that can be framed in justice terms (Wilcock, 1993, 1995, 1998). The other direction, concerned with critical social analyses of client-centered practice, discovered that the work of enabling client empowerment through occupation is congruent with social justice work (Townsend, 1993, 1996, 1998). Both research directions generated reflections on occupation and social justice and whether or not social justice sufficiently addresses the rights of persons, individually and collectively, to participate in meaningful occupations. Occupational therapists around the world are currently discussing whether occupational justice is but one important aspect of social justice or a concept on its own. Some argue that both concepts envisage ideal societies governed by a set of ethical, moral, and civic principles about the rights and responsibilities between people; the ways in which they treat and

relate to each other; societal liberties and freedoms; and the distribution of human and financial resources. Others argue that because social justice does not sufficiently address the difference between individual occupational natures and needs, occupational justice and social justice should be thought of as separate entities so that important aspects of occupational justice are not overlooked. Both perspectives acknowledge that all people are occupational beings with differing natures and needs and that meeting those needs is a matter of health, which makes it a matter of justice.

HOW TO DESCRIBE OCCUPATIONAL JUSTICE

There are no simple translations for the English terms *occupation* and *justice* to transcend cultural, linguistic, and social differences. Instead, consideration of four related terms is called for: *occupation, justice, social justice,* and, finally, *occupational justice.*

Occupation

Occupational therapists tend to hold different views about what the word *occupation* embraces. Here, *occupation* is used to mean all the things that people want, need, or have to do, whether of a physical, mental, social, sexual, political, spiritual, or any other nature, including sleep and rest activities. Occupation enables populations and communities to participate actively in shaping their own destinies (Thibeault, 2002) and can be health-enhancing or health-threatening. The duality of health or harm in occupation is a central tension that underlies occupational therapy.

Occupation is shaped by time, place, and social conditions and is a unit of economy. It is the practical, everyday medium of self-expression or of making or experiencing meaning because it is the activist element of human existence whether contemplative, reflective, and meditative or action-based performance. Occupation can provide the means to suppress the self, identity, being, belief, spirit, and autonomy as well as the means to express it. As a fundamental means of achieving implicit or explicit goals, power relations are central to possibilities and limitations. The power to participate in occupations may be controlled through physical force or invisibly through regulation and cultural expectations.

Justice

Justice has been defined in many ways throughout history. It has been equated with words such as *rights, equity,* and *fairness,* and Benjamin Disraeli (1851) described it as "truth in action." The term *justice* is most often applied to legal systems, but it is also used in arguing for equal dis-

tribution of resources and positive discrimination in terms of marginalized persons (Norton, 1994).

Social Justice

Social justice is a concept about rights, equity, and fairness. An accepted part of postmodern societies, this concept of justice centers on just social relations and conditions regardless of difference in race, class, gender, income, or disability. Social justice is applied to the ethical distribution and sharing of resources, rights, and responsibilities between people recognizing their equal worth as citizens, "their equal right to be able to meet basic needs, the need to spread opportunities and life chances as widely as possible, and finally the requirement that we reduce and where possible eliminate unjustified inequalities" (Commission on Social Justice, 1994, p. 1).

Occupational Justice

Occupational justice is also equated with words such as *rights, equity,* and *fairness.* It, too, is applied to the right of every individual to be able to meet basic needs and to have equal opportunities and life chances to reach toward her or his potential but specific to the individual's engagement in diverse and meaningful occupation. Occupational justice is a justice of difference because people have different natures, needs, and capacities that are expressed through what they do. Therefore, occupational justice requires ethical distribution and sharing of resources, rights, and responsibilities with regard to what individuals want, need, or are obliged to do within the social and ethical standards of a community. Occupation is what brings us to the reality of daily life, where we can talk about the everyday individual, group, and population experiences of occupation that occur within broad social conditions and structures that shape options for and against justice.

Social and occupational justice provide different perspectives for raising questions around a shared interest in justice (Figure 20.1). An exploratory theory of occupational justice proposed by Townsend and Wilcock (2004) suggests how these four ideas—occupation, justice, social justice, and occupational justice—relate to each other.

The theory presented in Figure 20.2 assumes that people are occupational beings, that they participate in occupations as autonomous beings, that participation is interdependent and contextual, and that it is a determinant of health and quality of life. The theory proposes the principles of empowerment through occupations; an inclusive classification of all occupations; individual and collective enablement of occupational potential; and diversity, inclusion, and shared advantage in occupational participation.

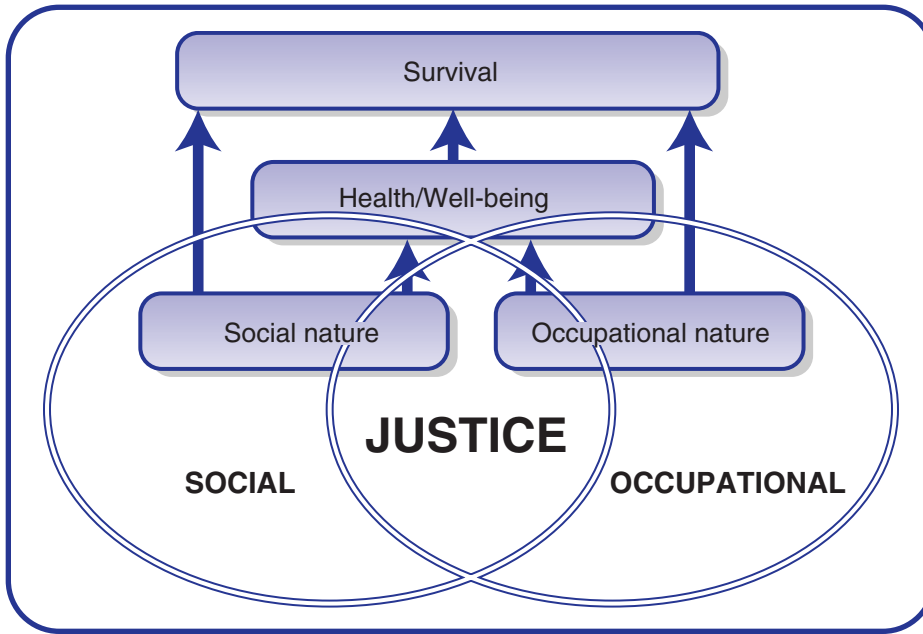
The primary purpose for developing the theory of occupational justice was to draw attention to the fact that


FIGURE 20.1 Occupational justice and social justice enabling the meeting of biological needs.

throughout the world, people are constrained, deprived, and alienated from engaging in occupations that provide personal, family, and/or community satisfaction, meaning, and balance through what they do. In many cases, people are unable to provide the necessities of life that are prerequisites to health:

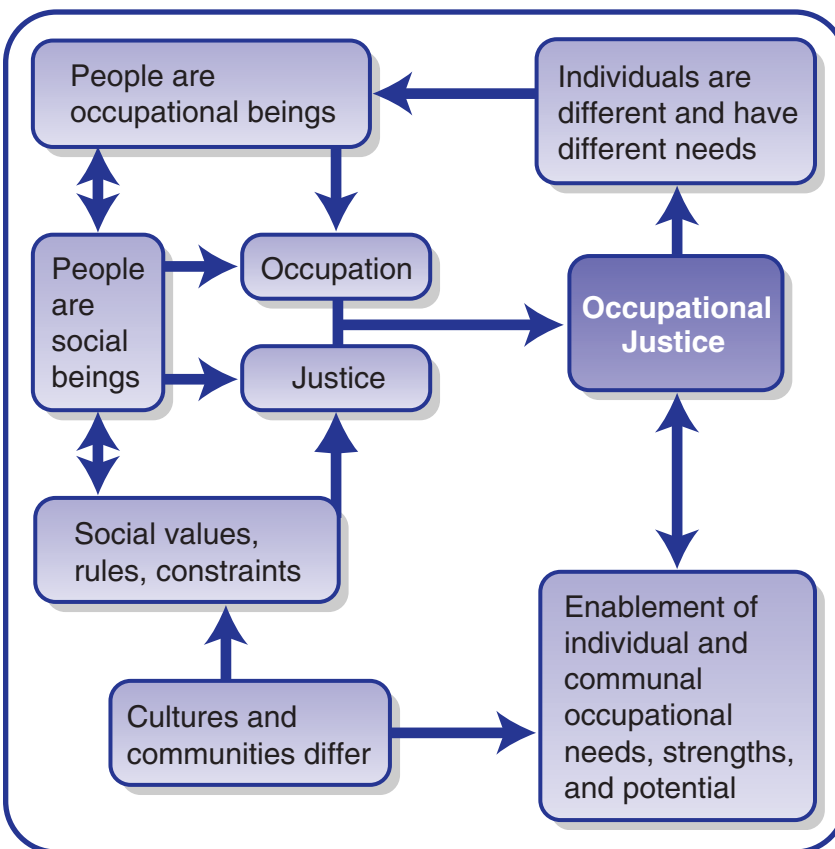
The fundamental conditions and resources for health are peace, shelter, education, food, income, a stable eco-system, sustainable resources, social justice and equity. (World Health Organization [WHO], Health and Welfare Canada, Canadian Public Health Association, 1986, p. 2)


FIGURE 20.2 An exploratory theory of occupational justice: intersecting ideas. (Reproduced with permission from Prentice Hall.)

The World Health Organization (WHO) recommends action to promote health for all in many of its directives, such as the Ottawa Charter for Health Promotion (WHO et al., 1986), which calls not only for the satisfaction of needs and coping with the environment, but also for the realization of aspirations of physical, mental, and social well-being. *Health for All in the Twenty-first Century* (WHO, 1998) validates "the uniqueness of each person and the need to respond to each individual's spiritual quest for meaning, purpose and belonging" as part of health and as a matter of justice.

During the 1990s, the development of "active societies" and "enabling states" was addressed within international organizations (Gilbert, 1995; Kalisch, 1991, pp. 3–9; Organization for Economic Cooperation and Development [OECD], 1989). The Clinton Administration, for example, encouraged a Progressive Policy Institute "blueprint for a new America" in which

> the enabling state be organized around the goals of work and individual empowerment. . . . Above all, it should help poor Americans develop the capacities they need to liberate themselves from poverty and dependence. . . . An enabling strategy should see the poor as the prime agents of their own development, rather than as passive clients of the welfare system. (Marshall & Schram, 1993)

The Universal Declaration of Human Rights (United Nations [UN], 1998) advocates for all people to have a standard of living that is adequate for health and well-being. Advocacy is for people to have equal rights to work; to free choice of employment; to rest, leisure and holidays; to participate in the cultural life of a community; to engage in the arts and scientific advancement; to take part in national governments; and to fully develop the human personality. This declaration of fundamental rights for all provides topics for debate centering on notions of empowerment, choice, and opportunity; the tension between individual and community rights; and the tension between justice for individuals and the common good. The need for such rights to be considered part of intervention in health care is worthy of debate at all levels. Occupational therapists can enter this debate by addressing the need for participation in occupations that meet people's individual natures, capacities, and choice and how these relate to health and well-being.

RECOGNIZING THE PLACE OF OCCUPATIONAL JUSTICE WITHIN OCCUPATIONAL THERAPY

In addition to occupational therapy publications that focus on justice, such as *Spirit of Survivors: Occupational Therapy Without Borders* (Kronenberg, Algado, & Pollard, 2005), occupational justice ideas are influencing the governance, planning, and professional policies of occu-

pational therapy's professional organizations. The British College of Occupational Therapists (COT, 2002) put forward a strategic plan founded on contemporary ideas of health and social justice. In 2005, COT argued that equality and social justice are central to the professions' conceptual framework in that "occupational therapists have long worked with the most excluded and disadvantaged people to enable them to achieve fulfilling lives as members of communities." COT goes on to state:

> The profession uses the term 'occupational justice' to refer to the concept that acts as a complementary extension to social justice. Occupational justice provides a framework for asking questions about inequities of opportunity for occupational development, or inequities related to lack of appropriate enablement for those living with a disability (p. 2–3).

The European Network of Occupational Therapists in Higher Education embraced occupational justice as the theme of its 2003 annual conference. At that meeting, Townsend (2003) asked, "Why would occupational therapists be concerned with occupational justice?" Responses centered on the injustices that occur when humans are barred, trapped, confined, segregated, restricted, prohibited, unable to develop, disrupted, alienated, imbalanced, deprived, or marginalized in ways that exclude them from participating optimally in the occupations they need and want to do to sustain health throughout the life course.

The World Federation of Occupational Therapists (WFOT) also recognizes an increasing need for occupational justice to counter the sociopolitical and economic factors that underlie and are a consequence of disability. The WFOT affirms that "many people with disabilities are restricted in or denied access to dignified and meaningful occupation in their daily life and their well-being is sometimes compromised through occupational apartheid and/or occupational deprivation" (WFOT, 2004–2005, p. 2). In addition the international professional body has drawn up a Human Rights Position Statement that addresses issues of occupational justice (WFOT, 2006).

Today's practice of occupational therapy may actually rest on the profession's success in putting occupational injustice explicitly on the public agenda and showing what an occupation-focused, justice-driven profession can accomplish. Imagine, for instance, the power of reducing occupational disruptions for workers who have lost their jobs because of work-related injuries, of minimizing the occupational alienation and imbalances of people who live with severe and persistent mental illnesses, of fostering the occupational development of children with disabilities. Further, imagine the potential impacts of advocating for and participating in a restructuring of global economics and practices on the collective crises of war, refugees, dislocation of cultural groups, or natural disasters in which occupational deprivation, marginalization, or apartheid is the implicit and often taken-for-granted result.

WHAT TO DISCUSS WITH OTHERS ABOUT THE NATURE OF OCCUPATIONAL JUSTICE OR INJUSTICE

Occupational justice draws together two powerful biological needs: the need to do and the need to be part of a social group. Both are innate survival mechanisms, as archaeological and anthropological research demonstrates (Wilcock, 1998, 2006). The association of well-being with supportive relationships is strongly supported by research (Argyle, 1987; Blaxter, 1990; Cohen et al., 1982; Isaksson, 1990; Warr, 1990). The association of well-being with occupation is less well recognized but was supported in a survey in which participants were asked to define their concept of well-being (Wilcock et al., 1998, 2006). The most common responses to a question about the situation or environment they associated with feelings of well-being related to occupation, although the word *occupation* was not used. Instead, participants spoke of leisure, achievement, work, rest, selfless activity, self-care, and religious practices. The next most common response was related to relationships, suggesting that what people do and having others to do it with are central to well-being.

The term *occupational justice* can be used to attract media attention to issues that might otherwise be ignored by those concentrating on technical aspects of recovery or concerned with cost containment and efficiency in intervention. After the first Canadian Symposium on Occupational Science, the Canadian Broadcasting Corporation interviewed Patricia Manuel (2003) about the potential occupational deprivation that is experienced when natural areas used for informal play by children living in the city are usurped by housing developments. Manuel's references to occupational justice reframed the implications of urban planning.

MAKING OCCUPATIONAL JUSTICE EXPLICIT IN OCCUPATIONAL THERAPY PRACTICE

Three scenarios illustrate occupational therapy practice with clients whose justice concerns are related to aging, social problems, and immigration.

Occupational Injustice and Old Age

Older adults can be trapped in a narrow life with limited opportunity, little chance of fulfillment, poor health, reduced well-being, reduced quality of life, and feelings of disempowerment to determine their own destiny. As a matter of justice, all older adults require options for health-enhancing occupations. To deny them options for such participation is more than a matter of medical care. Not all older people are infirm, demented, or unable to strive

toward personal goals, as some managers of services to the aging population might imply. Many older adults remain interested in the future and the part they will play in it. They remain interested in doing whatever has meaning to them unless, as too commonly happens, they are confined in or shackled to restricting, disempowering situations in the care of patronizing, "for your own safety," overzealous caregivers. Provision of opportunity to meet unique occupational wants and needs is a matter of justice as part of an active aging process. There is little emphasis in health, social welfare, or popular literature on encouraging older people to engage actively in the aging process. There are exceptions perhaps with regard to those who do exceptional things at a very advanced age and are deemed extraordinary. The increasingly litigious nature of Western societies is, in itself, counter to occupational justice for older people. Fear of legal action should accidents occur if older people engage in more than self-care occupations has resulted in many excellent programs being axed owing to risk management concerns. From an occupational perspective, program limitations or an overemphasis on risk for seniors is discriminatory and unjust (Wilcock, 2005).

These everyday struggles are situated in a social context. Thus, occupational therapists would analyze more than physical or mental impairments and might raise critical questions to make explicit matters of occupational justice, as illustrated with reference to seniors in Box 20.1.

BOX 20.1

OCCUPATIONAL INJUSTICE AND SENIORS: A CHECKLIST

1. Sitting alone in nursing homes or other confined settings with nothing to do except to watch others in the same situation or a television that shows program after program that they did not choose
2. Taken for outings they have no interest in
3. Not attended to when they talk about what they have done in their lives
4. Not asked for advice or listened to when they give it
5. Given no chance to help others
6. Prevented from doing what they want in the name of risk management
7. Told they can't do something they would enjoy "for their own good"
8. Not allocated resources, helpers, services, or support to find satisfying occupations
9. Social contact only with paid service providers who bring food and change their bedding
10. Restricted, deprived, or alienated by the policies of people in authority or by legislation

Occupational Injustice and Social Problems

Economic rationalism and bureaucratic legislation have led to many people being unable to obtain regular paid employment that meets their interests and skills or to be self-employed. Condemned to living on social support or to engage in unsatisfying, often part-time employment, they experience long-term, negative health effects. For example, some people lose the self-esteem required to take personal responsibility for promoting their own health. Other negative effects may include the loss of income to eat healthy food, or disconnectedness from coworkers with whom occupations were previously shared. People might prefer to accept social security instead of paid employment because there are no financial or social incentives to work part-time. Families might be caught in employment policies that expect them to do too much or lose their jobs. Unemployment may actually be welcomed by those with alternative, subsistence occupational skills, such as growing vegetables, chopping wood, and repairing goods for reuse and recycling. People without such skills or the opportunities to engage in subsistence occupations may live unhealthy, occupationally deprived, unbalanced, or alienating lifestyles.

An occupational perspective can bring new insights to social problems. Thus, occupational therapists would attend to occupational injustices by raising questions about daily life, as illustrated in the case study that follows.

Occupational Injustice, Environmental Degradation, Refugeeism, and Immigration

In agricultural economies, many people are in dire need of help to obtain the prerequisites of health because of environmental degradation caused, at least in part, by the greed of multinational organizations and citizen disempowerment. Many people are occupationally deprived owing to war, political upheavals, and rigid dictatorships or because of natural disasters. The effects of occupational injustice in the immediacy of people driven from their homes by war or environmental disasters may take time to manifest and, because of this, are unrecognized or unheeded. Large numbers of displaced people are warehoused in refugee camps where they have very little to do or where life consists of subsistence occupations and occupations of persistent self-protection from violence and abuse. Some people recognize the impossibility of remaining in restrictive or alienating conditions and seek a better future in another land. There, they may be disadvantaged by refugee protocols, even to the extent of being segregated in detention centers while seeking right of entry. During formal immigration processes, most people will have access to a very restricted range of occupations. They continue to experience occupations that are far from health giving and that are unjust in terms of either human rights or health needs. Quality of life, empowerment, and social inclusion in occupations

---

CASE STUDY: *Petra: Occupational Injustices and Social Problems*

Eight-year-old Petra is a small, thin, shy, pleasant girl with poor school performance. She attends an after-school day care program run by municipal community services in part because of her need for extra school support and in part because no one is available at home for her after school. Her mother Juliana, age 35, works at two jobs just to keep her daughter rather than accepting the social worker's advice and putting Petra in a foster home. Petra's 12-year-old sister, Aggie, is becoming a wild teenager whose school performance is satisfactory, although her attendance is dropping rapidly. Aggie gets Petra ready for school because Juliana's first job starts at 5:00 A.M. Weekend time for Juliana is virtually nonexistent, because of the extra sewing that she does to make ends meet. A women's career development center has referred Juliana to a Job Skills for Women Program operated by the municipal community services. The municipal welfare office has employed an occupational therapist consultant to work with the five after-school and ten job skill development programs they operate. The professional team includes resource and special education teachers as well as social workers.

An occupational perspective can bring new insights to social problems. Thus, occupational therapists would attend

to occupational injustices by raising questions about daily life, as illustrated in the case study of Petra.

Sample Questions to Analyze Occupational Injustices and Social Problems

1. Who would the occupational therapist name as clients: Petra or Aggie, Juliana as a single mother, after-school programs, job skills programs, the municipality?
2. What documentation will demonstrate accountability for occupational therapy practice: Assessment of spirituality and the physical, mental, and cognitive occupational performance of individuals; program consultation descriptions; population data on children and single parents; program costs and outcomes?
3. What are the occupational concerns for children and adolescents who are not thriving in poor social conditions? For single women or men?
4. Who are the occupational therapists' allies in working for occupational justice?

CASE STUDY: *The El Khalil Family: Occupational Injustices and Immigration*

The El Khalil family were overjoyed when they arrived as refugees and new immigrants in Canada. Both parents are physicians, and the four children, aged 13, 12, 9, and 5, had been successful in school in their North African homeland. After two years of immigration challenges to their refugee status, the parents are both employed as school crossing guards. With little income, they live in a rundown one-bedroom apartment in a tough neighborhood, where the 13-year-old son has just been charged with assault as a young offender. He has been sent for observation to a youth detention center, where an occupational therapist is employed on a mental health team.

Sample Questions to Analyze Occupational Injustices and Immigration

1. What changes in occupational routines, locations, and supports have likely occurred for the family since immigration?
2. What occupational concerns are the family juggling?
3. From an occupational perspective, what will the boy gain and lose by admission to a detention center?
4. What public education would highlight the occupational issues associated with immigration and youth detention and the need to address occupational injustices?

are matters of justice and of health, as the case study above illustrates.

HOW TO ADVOCATE OR MEDIATE TO ENABLE CLIENTS TO PARTICIPATE IN MEANINGFUL OCCUPATION

Delivering occupationally just programs may entail keeping awareness of the occupational nature of clients in the forefront during any interaction; engaging people in dialogue about their perceived occupational needs; assessing according to those needs; and implementing programs that ensure that needs are met. Delivering occupationally just programs also entails advocating for occupational justice and mediating between competing intervention and resource priorities. The use of powerful arguments and the media to increase awareness may be called for. This entails being cognizant of and using occupational language, being available for public dialogue about enabling and inclusive social structures and occupation policies, knowing when and how to talk about occupational justice issues, and being ready to advance public understanding.

Both the UN and WHO are useful sources of accepted "health speak" and "justice speak." The WHO's (2002, p. 2) theme of Active Ageing, for example, provides a Policy Framework for discussion and action to promote healthy aging. The framework examines the need to prevent discriminatory action that can be counterproductive to well-being and to enabling those who are able to continue to contribute to society in important ways, posing questions that might be useful advocacy tools (WHO, 2002). Raising awareness among the general public is just as important as writing for occupational therapists or other health professionals. On any and every occasion, it is important to introduce the notion of occupational justice

and the view of people as occupational beings. All people need to be able or enabled to engage in the occupations of their need and choice; to grow through what they do; and to experience independence or interdependence, equality, participation, security, health, and well-being.

The History of Occupational Therapy

DON M. GORDON

Learning Objectives

After reading this chapter, you will be able to:

1. Articulate the relationship of moral treatment to the founding of occupational therapy.
2. Understand how new ideas concerning the relationship between the mind, body, and health created an environment that was ripe for the emergence of occupational therapy.
3. Understand how the world wars influenced the growth and development of occupational therapy.
4. Understand how ongoing projects in the occupational therapy community relate to historical concerns.

INTRODUCTION

The history of occupational therapy is integrally linked to the time of its origination and development. Although occupational therapy is a relatively recent idea, generated in the early years of the twentieth century, the recognition of the healing effects of occupation goes back thousands of years. The history of occupational therapy itself is also a story of the development of a scientific understanding of occupation. This look at the history of occupational therapy will begin with a look at the origins of the understanding that occupation influenced health. Then we will track the development of the profession of occupational therapy. This will include understanding the growth of science and professionalism in the larger culture and how these factors affected the development of occupational therapy. Uncovering these issues is fundamental to understanding how the expanding influence of science and medicine led to the origin of occupational therapy.

THE PREHISTORY OF OCCUPATIONAL THERAPY

Early observations of the healing effects of occupation are virtually as old at the written word itself; the first references to the use of occupation in healing go back to the Egyptians (American Occupational Therapy Association, 1967; Pinel, 1806/1962). The oldest observations of the healing effects of occupation and their use as part of a therapeutic program began in the treatment of "madness" or "insanity"—what is today known as mental illness. For example, Thomas Willis (1621–1675), who coined the word *neurology* and is immortalized in the term *circle of Willis* recognized the value of occupation in the treatment of insanity. He advocated directing patients toward occupations that promoted "cheerfulness and joy," such as music, dancing, singing, hunting, fishing, and even chemical and mathematical studies (Hunter and Macalpine, 1963). However, this understanding was less than widespread, and medical treatment of the insane consisted primarily of bloodlettings and "nausea treatment," the use of purgatives and emetics to weaken and help control patients. Daily whippings or beatings were also utilized, given that physical abuse was the most expedient means of controlling behavior (Kraepelin, 1917/1962). It was not until the beginning of the nineteenth century that a greater understanding of the healing potential of occupation was utilized in a more widespread manner. Then, with the birth of the asylum, a fundamental advance in the treatment of the insane came about: moral treatment.

THE BIRTH OF THE ASYLUM AND MORAL TREATMENT

With the birth of the asylum in the beginning of the nineteenth century, the treatment of the insane underwent a fundamental shift toward a more humanitarian approach. The word *asylum* is derived from the Greek and Latin root signifying a place of refuge and protection (*Oxford English Dictionary,* 1971). The asylum was viewed as a reformative institution that represented an optimistic and hopeful possibility for the humane treatment of insanity (Porter, 1997). The birth of the asylum also brought medicine formally into the treatment of the insane. In 1808, Riel coined the term *psychiaterie* for the new discipline directed toward the cure of mental disorders (Shorter, 1997). Its most fundamental practice was moral treatment, intended to replace brutality with kindness and idleness with occupation. Moral treatment described a general approach to care of the insane summarized nicely by William Browne in 1837: "moral treatment . . . may be summed up in two words, kindness and occupation" (as cited in Shorter, 1997, p. 43).

The history of occupational therapy has long been associated with moral treatment (for some examples, see Bing, 1981; Bockoven, 1963, 1971; Hopkins, 1978, 1988; Kielhofner and Burke, 1977; Peloquin, 1989, 1994). Moral treatment was a social reform movement concerning the care of the insane that was a blend of Enlightenment optimism (Bockoven, 1963; Peloquin, 1989, 1994; Szasz, 1974) and folk wisdom (Porter, 1997). A fundamental belief that the insane remained creatures of reason meant that their treatment demanded compassion rather than cruelty. This reform was part of a larger social reform movement that included the penal system, working conditions, and the rights of children (Rosen, 1968). There were also very practical reasons for the changes in the treatment of the insane patient. Many superintendents of "madhouses" recognized that the daily whippings and beatings accompanied by the widespread use of emetics, purgatives, and bloodlettings that were common in the treatment of the insane led to the demise of those in their care more frequently than cure. It was observed by some that a focus on the management of behavior while minimizing the use of medical treatments restored a greater number of those in their care (Hunter and Macalpine, 1963). Out of these observations and the spirit of reform generated by the times, moral treatment was born. Moral treatment has been considered one of the three most significant advances in medicine in the nineteenth century, along with antisepsis and anesthesia (Hunter and Macalpine, 1963).

Occupations were an essential element of the moral treatment of the insane. Some doctors initially favored the use of agriculture (Rush, 1812/1964), but as the nineteenth century progressed, the occupations that were used in the application of moral treatment expanded. Various forms of manual labor, including agriculture, tailoring, working in the shoe shop, and sewing, were among the various occupations utilized. Many occupations were also related to the maintenance of the institution and even as contracted labor in the community, a practice that was certainly utilitarian though at times controversial (Bockoven, 1963; Dain, 1971; Grob, 1966). Religious worship was also a common component, as many asylum superintendents in the United States were men of strong religious underpinnings (Dain, 1971; Grob, 1966).

Although moral treatment was truly a remarkable advance in the treatment of the insane, it had faded from the limelight by the end of the nineteenth century. The concept that the insane deserved humane treatment was not lost but remained as one of the basic practices and principles in the practice of psychiatry (Hunter and Macalpine, 1963). The term *moral treatment* fell into disuse for several reasons. One fundamental reason for this decline in the use of this term was that moral treatment was not specifically a medical treatment. Clergymen, philosophers, and jurists all claimed authority over the practice of moral treatment (Vandermeersch, 1994). In addition, the authority of the moral treatment superintendent emanated from the moral and social order, not from scientific knowledge

(Grob, 1994). In the latter half of the nineteenth century, medicine continued to garner power, and its practices became increasingly linked to scientific knowledge (Kimball, 1992; Starr, 1982). This exposed another fundamental problem with the foundation of moral treatment, for it was not scientifically based. By the close of the nineteenth century, science was becoming one of the most powerful elements of American culture (Bledstein, 1976; Burnham, 1987; Daniels, 1971; Ellenberger, 1970; Kimball, 1992; Reingold and Reingold, 1981, Rosenberg, 1997). As medicine took over the practice of treating the mentally ill, the unscientific jargon of moral treatment fell by the wayside and was replaced by a new treatment approach: psychotherapy. While many have argued that moral treatment was discredited and discarded (Bockoven, 1963, 1971; Peloquin, 1989, 1994), this appears not to be entirely the case. The growth of science and the birth of psychotherapy set the stage for the emergence of a new profession: occupational therapy.

THE BIRTH OF OCCUPATIONAL THERAPY

The genesis of occupational therapy occurred during a remarkably dynamic time of cultural change in American history as well as the history of medicine, marked by dramatic changes in lifestyles and habits (Allen, 1952). Science and modernization held the promise of improvement. "Science, efficiency, speed, and movement—these were the ideals" (Jones, 1971, p. 150). Darwin's theory of evolution illustrated the potential for science to address issues that had previously been considered outside of its reach (Hollinger, 1995). Science came to play a much larger role in social policies, prompting W. J. Mcgee to claim in 1898 that "America has become a nation of science" (as cited in Daniels, 1971, p. 295). Though the relationship of science to social thought is often overlooked (Rosenberg, 1997), science was possibly the most powerful cultural force in the twentieth century (Daniels, 1971; Fuller, 1991; Shumway and Messer-Davidow, 1991).

Until the latter part of the nineteenth century, consideration of the psyche or mental processes in the role of health had essentially been ignored by medicine. Mental illness was viewed as the product of somatic disease or dysfunction. The prevalent belief in a Lockean concept of consciousness, the "tabula rasa," meant that all mental processes were believed to be under conscious control, precluding unconscious psychic processes (Hunter and Macalpine, 1963). At the end of the nineteenth century, new ideas about "nervous energy" and the role of the psyche in mental illness and health were revolutionary. Views of consciousness and the unconscious changed dramatically. Then a confluence of events occurred that propelled the psyche into the forefront of medical practice: (1) the success of the rest-cure, (2) the successes of the Christian Science movement, and (3) the psychodynamic revolution and the birth of psychotherapy. With the birth of psychotherapy, the stage was set for the introduction of a new profession: occupational therapy (Gordon, 2002).

After the discovery of the electrical nature of the nervous system in 1852, many theories were developed to explain the regulation of one's nervous energy (Rosenberg, 1997). One of the more influential practices was generated by Silas Weir Mitchell's "rest-cure." The rest-cure was envisioned as a somatic treatment, with rest and a milk diet theorized as being integral to the restoration of one's "nervous battery." This treatment was devised to cure the physical exhaustion that led to nervous illness and was immediately successful and much copied. However, physicians soon recognized that the most powerful element of the cure was the suggestive power of the physician, intensified by the isolation that was part of the treatment (Shorter, 1997). This somatically based treatment thus was one factor that demonstrated the psychological element of healing, helping to stimulate the recognition of the role of the mind in healing and the mind-body connection.

To appreciate this emerging recognition of mind-body unity, one must also consider the cultural events that supported these concepts. Faith healing, "mind-cures," and New Thought movements represented a variety of alternative schemas of healing that were designed to replace or supplement traditional medical beliefs (Haller, 1981). The most significant of these mind-cures was the Christian Science movement, or Eddyism, named after its founder, Mary Baker Eddy (1821–1910). This movement sought to scientifically master the teachings of Christ in order to reestablish his mission to heal the sick. A tenet of Christian Science was that disease was an abnormal condition that could be remedied through proper exercises of the mind. Christian Science became very popular, reporting countless cures.

However, these claims of cure were considered an outrage to the medical community of the time, which was now fervently engaged in the pursuit of developing the science of medicine. Though these claims to healing were rejected, they could not be ignored. To address this issue, Henry Goddard of Clark University conducted a study in 1898, which found that there was nothing incompatible in the simultaneous use of both drug therapies and mental therapeutics; in fact, the two were found to be mutually reinforcing (Haller, 1981). Goddard's findings helped to open the door to stake a claim to mental therapeutics in the science of medicine. The successes of faith healers were viewed not as displacing medicine but as highlighting the medical community's disregard concerning the role of the mind in healing, with medicine emphasizing drug therapies up until this time. The success of Christian Science set the stage for medicine to take a more holistic stance regarding human health that incorporated both the mind and body (Haller, 1981).

The late nineteenth and early twentieth century were also marked by the emergence of dynamic psychiatry. At this time in history, the treatment of mental disease was in the midst of radical change. The ideas of Emile Kraepelin, Pierre Janet, Sigmund Freud, and William James were changing the way in which nervous illness and the path to cure were conceptualized. Theories of nervous energy and how the psychic forces influenced physical and mental health were generated to further understand the mechanisms behind health and illness. The word *psychotherapy* was coined in 1891 to describe a new and groundbreaking form of medical treatment (Ellenberger, 1970). The new profession of occupational therapy, which was initially considered by some as a form of psychotherapy (see Barker, 1908; Carroll, 1910; Schwab, 1907), emerged from the world of dynamic psychiatry.

OCCUPATIONAL THERAPY: A NEW TREATMENT APPROACH

The early founders of occupational therapy endeavored to create a new role for occupation in the process of healing both the mind and the body. Although early writers certainly acknowledged the age-old tradition of the use of occupation as a curative measure, including moral treatment (for early examples, see Dunton, 1919b; Slagle, 1914), the systematic use of occupation was seen not as a continuation of past practices but as a truly new endeavor in therapeutics (Dunton, 1919b; Hall, 1910a). The critical difference between prior practices and occupational therapy was the systematic nature of how occupation was utilized and the integration of scientific knowledge formations in understanding the therapeutic effect of occupation (Gordon, 2002).

From the time that physicians began to utilize occupation as a therapeutic measure in the early twentieth century, they endeavored to understand the healing effect of occupation in scientific terms. Scientific knowledge is not only the foundation of professional legitimacy (Bledstein, 1976; Kimball, 1992), but possibly the most powerful cultural force in the twentieth century (Daniels, 1971; Fuller, 1991; Shumway and Messer-Davidow, 1991). What was considered science in the early twentieth century was quite different from our current conceptualization of science. An older view of science persisted into the early twentieth century that perceived knowledge gained of the natural world as "science." This meant that virtually any technique or process that produced positive results was viewed as "science." In the United States, those who were involved in occupations related to scientific disciplines and applied professions such as medicine or engineering were considered scientists, and their work was considered to be science (Reingold and Reingold, 1981). The attempt to understand the therapeutic effect of occupational therapy in scientific terms was certainly integral to the profession from its early implementation.

At the dawn of the twentieth century, the rest-cure remained the preeminent treatment for nervous illness. However, this treatment supported by a somatic rationale came under fire from a physician who had a staunch belief in the power of occupation: Herbert Hall. Hall was a physician who treated nervous illness and one of the early leaders of occupational therapy. For him, the rationale for the rest-cure failed to recognize the fundamental role of the psyche and one's day-to-day behavior in the etiology of nervous illness. Hall (1905a) constructed the "work-cure" as "a practical protest against the almost universal application of rest in the treatment of neurasthenia and allied conditions." (p. 29). For Hall (1905b), poor lifestyle adjustment and worry meant that "the patient's whole personality is at war with the environment" (p. 48). The resulting nervous depletion was not the same as the rest-cure postulated by Mitchell, but Hall considered nervous illness as having psychic causes in addition to somatic etiologies. In these early writings, we see the combination of somatic and psychic concepts of illness and healing, producing a conceptual unification of mind and body.

In the early twentieth century, scientific rationales for treatment ranged from the purely physical to the exclusively psychic, though a blend of the two factors is generally seen in the early literature. For example, by exercising, the body occupation restored physical health, which in turn restored mental health (Cohn, 1908; Moher, 1907; Neff, 1910). Occupation helped to boost the nutrition of nerve cells and rid them of toxins en route to addressing nervous illness (Hall, 1905b; Moher, 1907; Willson, 1908). Neff (1910) argued that occupation improved happiness, which in turn fortified the blood, stimulated the metabolism, and improved sleep, digestion, and the functioning of every organ in the body.

Psychic explanations viewed the therapeutic use of occupation as taking a "synthetic" approach (Hall, 1910b; Thayer, 1908). This terminology distinguished this synthetic school of thought from the analytic approach commonly associated with Freudian psychotherapy. Rather than searching for "first causes" of psychopathology in an attempt to ultimately restore unity to one's psychic functioning, the synthetic approach addressed the behavior problems manifest in an unbalanced lifestyle, aiming to achieve synthesis through the unity of thought and action (Hall, 1910b). This addressed a concern of many of the physicians of the time with the analytic method, for morbid introspection was a common malady in those with nervous illness. Given that unhealthy attention to "self-consciousness and self-concern" (Hall, 1910b) only worsened the disease process, a therapeutic technique that was based on intense self-analysis appeared dangerous in the hands of all but the most highly trained physicians (Atwood, 1907; Hall, 1910b, 1923; Schwab, 1908; Thayer, 1908). Therapeutic occupation produced its therapeutic

effect by redirecting one's thought down healthier channels, avoiding "useless self-analysis" (Hall, 1910b). While this collection of scientific rationales for the effectiveness of treatment might seem rather insubstantial by today's standards, scientific investigation had a very different meaning at the beginning of the twentieth century from that of today.

THE FORMATION OF OCCUPATIONAL THERAPY'S PROFESSIONAL ORGANIZATION AND BIRTH OF THE PROFESSION

In March 1917, a small group of individuals, including medical doctors, nurses, architects, social workers, secretaries, and teachers of arts and crafts, were brought together by the idea that occupation could play an important role in healing and health (Figure 21.1). (Dunton, 1918a, 1918b).

The practices that made up the future profession of occupational therapy were scattered throughout the medical community, but with this meeting in 1917, the National Society for the Promotion of Occupational Therapy (NSPOT), later renamed the American Occupational Therapy Association (AOTA), brought these practices together. This meeting marked the origins of the profession of occupational therapy. To understand just what this means, it is important first to define *profession.* Kimball (1992) defines a profession as "a dignified occupation espousing an ethic of service, organized into an association, and practicing functional science" (p. 16). The fledg-

ling profession of occupational therapy endeavored to fashion itself in this image. George Barton, the first president of NSPOT, was in fact pivotal in the naming of the profession, having the foresight to insist on the term *therapy* in the organizations name (Barton, 1917, personal communication to William Rush Dunton). Therapy is defined as "the medical treatment of disease" (*Oxford English Dictionary,* 1971, p. 3284). Barton's insistence on the use of the term *occupational therapy* reinforced the future profession's inclusion within the realm of medical science. He also promoted the use of medical language to promote the legitimacy of the professional base of occupational therapy. Occupational therapy closely allied itself with the medical profession, envisioning prescription and medical supervision as necessities (Dunton, 1928; Hall, 1923; Kelleher, 1925; Richardson, 1926). The new profession of occupational therapy rooted itself in medical science to establish legitimacy, for "Any form of therapy that does not rest upon science in the true sense of the word becomes a cult or worse, quackery" (Robinson, 1925, p. 2).

However, the founders were somewhat ambivalent toward the name of this new profession. William Rush Dunton, one of the founders of NSPOT and visionary figure in the first decades of the profession struggled with "the cumbersomeness of the term occupational therapy" (1919a, p. 36), as it lacked the "exactness of meaning which is possessed by scientific terms" (p. 36). Other titles such as "work-cure," "ergotherapy" (*ergo* being the Greek root for "work"), and "creative occupations" were discussed as substitutes, but ultimately, none possessed the broad meaning that the practice of occupational therapy demanded in order to capture the many forms of treatment that existed from the beginning (Gordon, 2002). Though practitioners continue to struggle with the abstract nature of the term *occupational therapy* to this day, the name of the profession appears to have been well chosen.

In the early years of occupational therapy, the predominant therapeutic activities that were used comprised a great variety of handcrafted goods and activities (Figure 21.2). At times, the salability of these goods was critical to the economic viability of the institution (see Hall, 1905a, 1905b, 1910a, 1910b). However, this was a point of contention even among early leaders, who were fearful that this would diminish the therapeutic mission of the new profession (Barton, 1917, personal communication to William Rush Dunton; Kidner, 1932). Other forms of therapeutic interventions were encouraged from the beginning of the profession, including the use of recreation, music, and art. Although crafts were initially the principal form of occupational therapy used with children (Clark, 1925; Conrick, 1930), the fundamental value of play as the most fundamental occupation for children was quickly recognized (Clark, 1925; Mackay, 1933; Obrock, 1932).

THE PHILOSOPHY OF OCCUPATIONAL THERAPY

From the time that physicians began to articulate a concept of the therapeutic application of occupation, a scientific philosophy of work and occupation began to be developed. New ideas such as Darwin's theory of evolution were changing conceptions of human nature in unforeseen ways (Hollinger, 1995). Physicians endeavored to understand the role of occupation within the span of human evolution. The human capacity for work was seen as being a defining factor, "Work is truly life, and any treatment which ignores every means which will make possible such life in greater abundance, cannot be comprehensive." (Carroll, 1910, p. 2033). Human beings had evolved through work and action, making these elements of life a fundamental human need (Gordon, 2002).

But it was Adolph Meyer who most clearly articulated the philosophy of occupational therapy in his landmark article of the same title published in 1922 (Figure 21.3). Embodying the "Pollyanna spirit" that was widespread among health reformers of the time (Burnham, 1987), Meyer (1922) espoused the potential for scientific thought and progress to improve the human condition. The fundamental change in psychiatry had come about in viewing "mental problems as problems of living" (p. 4). He notes how the previous 30 years had yielded great gains in scientific understanding, particularly in physics with the rise of energetics and understanding the "applications of work" (p. 5). His seminal paper introduced occupational therapy's concern for coming to a fuller understanding of the role of time in one's life, or temporal adaptation. Meyer (1922) noted that just as our heart beats in a rhythm, so do we respond to the greater rhythms of day and night, sleeping and waking, and hunger and
FIGURE 21.3   Adolf Meyer, renowned psychobiologist and author of The Philosophy of Occupation Therapy (1922). (Photo courtesy of the archives of AOTA, Bethesda, MD.)

satiation, all centered on the fundamental activities of human life: "work and play and rest and sleep" (p. 8). These ideas remain as touchstones of occupational therapy thought and practice to this day.

KEY EVENTS IN THE HISTORY OF THE PROFESSION

A variety of key events and relevant cultural forces were elemental to the growth and development of the profession of occupational therapy. In the early twentieth century, the newfound world of the psyche and medical treatment via psychotherapy opened up a new world of possibilities for treatment of the mentally ill and improving the quality of life of the general population. While Americans embraced science and technology, the rapid cultural changes and increasing pace to life were seen as a factor in the genesis of nervous illness. William James (1899/1918) believed that American "overtension and jerkiness and breathlessness" (p.59) was a "bad habit" that had slowly been acquired over the years. The challenge was to find a way to replace these traits with an appreciation of "harmony, dignity, and ease" (James, 1899/1918, p. 65). Herbert Hall (1910b) believed that the proper use of occupation could address these societal concerns, asserting that "many people are suffering in mind and body because of the attempt to accomplish too much, or from idleness which is not necessary, that a

therapeutic readjustment would mean preventive and curative medicine on a large and important scale." (p. 297). These remain challenging issues.

The early twentieth century was a time in which the rising incidence of disability related to industrial accidents, tuberculosis, World War I, and mental illness brought about an increasing social awareness of the issues involved. This created a growing concern about the need to increase societal efficiency, giving birth to the efficiency movement (Daniels, 1971). George Barton was a vocal proponent of efficiency techniques, including the "motion study method" (Barton, 1916, p. 82) of Kenneth and Lillian Gilbreth, efficiency experts during the early twentieth century. This attention to analyzing and understanding the ways in which to streamline activity marked the beginning of energy conservation practices in occupational therapy.

The entry of the United States into World War I was also a crucial event in the history of the profession. Up until this time, occupational therapy had been concerned primarily with the treatment of people with mental illness. However, U.S. involvement in the Great War and the escalating numbers of injured and disabled soldiers presented a daunting challenge to those in command. The military enlisted the assistance of NSPOT to recruit and train over 1,200 "reconstruction aides" to help with the rehabilitation of those wounded in the war. Given that "shell shock" was a common cause of disability during the First World War, these forerunners of occupational therapy provided treatment that was significant for its holistic approach, healing not only the body of the patient but the mind as well (Figure 21.4). This provided the boost in attention and interest that would help to eventually pro-pel occupational therapy into the status of a profession (Gordon, 2002; Quiroga, 1995).

The 1920s and 1930s were a time of establishing standards of education and laying the foundation of the profession and its organization. Eleanor Clarke Slagle proposed a 12-month course of training in 1922, and these standards were adopted in 1923 (Hopkins, 1978). Educational standards were expanded to a total training time of 18 months in 1930 to place the requirements for professional entry on par with those of other professions (Kidner, 1930). During this time, the psychodynamic paradigm continued to grow in influence, becoming the dominant schema for the scientific understanding of the therapeutic effect of occupation regarding one's mental health. Behaviorism and its studies of reaction time were seen as groundbreaking means for understanding human behavior and were influential in these early years as well (for examples, see Amar, 1922; Meyer, 1922). Various psychological schemas were incorporated and blended, concepts being taken from Adolph Meyer, Sigmund Freud, Carl Jung, Alfred Adler, and other influential thinkers in the world of psychology and psychiatry in this era. Incorporation of the most influential ideas concerning human psychology served to reinforce occupational therapy's claims to professional legitimacy and its alliance with medicine (Gordon, 2002). While the Great Depression of the 1930s presented a challenging time for the new profession, occupational therapy remained viable, continuing to raise educational standards. Then with the advent of World War II, the demand for occupational therapists again exploded, prompting new education programs and expanding membership in the field from a

mere 1,144 registered therapists in 1941 to 2,265 in 1946 (Hopkins, 1978).

WORLD WAR II AND THE GROWTH OF REHABILITATION

With entry into World War II and the ensuing skyrocketing demand for therapists to treat those injured in the war, the field of occupational therapy underwent dramatic growth and change (Figure 21.5). Occupational therapists needed to be skilled not only in the use of constructive activities such as crafts, but also increasingly in the use of activities of daily living (Hopkins, 1978). The changing science that surrounded the practices of rehabilitation of physical disabilities required accredited schools to undergo intense reorganization of their educational curricula. This prompted the publication of the first textbook in the United States written principally for occupational therapists to be published in 1947, edited by Helen S. Willard and Clare S. Spackman (Spackman, 1968) (Figure 21.6). Occupational therapy also began to expand its educa-
FIGURE 21.5   Wilma L. West, head of orthopedics occupational therapy, Walter Reed General Hospital, Washington, DC, 1943–1944. West was a founder of the American Occupational Therapy Foundation and its president from 1972 to 1982. She was also president of AOTA from 1961 to 1964 and Eleanor Clarke Slagle lecturer in 1967. tion into the graduate level, the first master's degree in occupational therapy being offered at the University of Southern California in 1947.

The profession continued to grow and redefine itself in the 1950s. Educational programs and the number of individuals entering the profession continued to increase, from 13 accredited schools in 1938 to 24 schools in 1960 (Hopkins, 1978). The profession also began to assess the potential for the use of trained assistants in the attempt to address the ongoing shortage of qualified therapists, and educational standards for occupational therapy assistants were implemented in 1960 (Hopkins, 1978).

CHANGES IN THE 1960S THROUGH THE 1980S

The 1960s and 1970s were a time of ongoing change and growth for the profession as it struggled to incorporated new knowledge and cope with the recent and rapid growth of the profession in the previous decades. New developments in the areas of neurobehavioral research led to new conceptualizations and new treatment approaches, possibly the most groundbreaking being the sensory integrative approach developed by A. Jean Ayres (Ayres, 1972, 1979). Ayres was influenced early on by the work of Margaret Rood and Carl and Berta Bobath in the treatment of neuromuscular dysfunction and Piaget, who examined the developmental process through a sensorimotor lens (Baloueff, 2003). Ayres incorporated an evolutionary perspective in her attempt to articulate how sensory experiences are understood, incorporated, and utilized by human beings to allow for adaptation in one's behavior. Her pioneering work in this area was remarkable in many ways, integrating new ideas about neuronal plasticity and the importance of sensory input into the normal and healthy development of the brain and nervous system. She continued to refine her ideas until her death in 1988. Her ideas continue to be further developed and increasingly incorporated in the understanding of child behavior and occupational therapy interventions to this day.

There had been profound growth in the profession in many ways since the Second World War, with growing ranks among occupational therapists, the introduction

of occupational therapy assistants, and the accompanying increase in educational programs. However, all this growth and change came at a cost, and some within the profession of occupational therapy felt that the profession had lost its moorings and had drifted from its originally charted course. Mary Reilly (1962) was one such voice (Figure 21.7).

Reilly believed that the profession had lost its focus on occupation and challenged the profession to work more diligently toward understanding occupation from an interdisciplinary perspective, including recent findings in sociology, psychology, philosophy, economics, and biology. She called for a return to the founding belief of occupational therapy "that man through the use of his hands as they are energized by mind and will, can influence the state of his own health" (Reilly, 1962, p. 2). Citing recent research on sensory deprivation, Reilly (1962) postulated that the human nervous system requires a wide variety of stimuli to maintain healthy sensory processing and that occupation is the vehicle through which we may experience this basic need.

The 1960s and 1970s appear to have been a time of introspection for many leaders in the field. In addition to Reilly's influential questions for the profession, others followed in her footsteps. Fidler (1966/2005) challenged the profession to recognize the professional commitment to learning, critical thinking, and creativity. She cautioned that the educational process must teach more than technical skills; instead, it should focus on basic principles and concepts that can be applied differentially in varied settings. Wilma West (1968/2005) exhorted the profession to look ahead and seek innovative avenues for treatment in response to the changing needs of society. West argued that the profession needed to move into the new role of "health agent," as prevention needed to become a more integral element of the health care system.

Elizabeth June Yerxa further extended this call to address our professional goals and status (Figure 21.8). Yerxa (1967/2005) noted that "the scientific attitude is not incompatible with concern for the client as a human being but may be one of the best foundations for acting upon that concern." (p. 128). However, she warned that occupational therapy had often not met the challenge of the profession, simply being content to apply knowledge at the level of technical skills and interventions. Yerxa believed that the profession must focus on its unique assets, such as allowing the client to exercise choice in the engagement of "self-initiated, purposeful activity" (1967/ 2005, p. 134). Ultimately, the goal of practice is to provide "authentic occupational therapy" (1967/2005, p. 138).

FIGURE 21.7   Dr. Mary Reilly created a frame of reference known as occupational behavior. She was the Eleanor Clarke Slagle Lecturer in 1961 and a charter member of the Academy of Research of the American Occupational Therapy Foundation. (Photo courtesy of the archives of AOTA, Bethesda, MD.)

FIGURE 21.8   Dr. Elizabeth J. Yerxa led the initial development of the academic discipline of occupational science. Dr. Yerxa received many awards for her work, including the AOTA Award of Merit for her leadership of the profession. (Photo courtesy of the archives of AOTA, Bethesda, MD.)

In achieving this goal, we may be truly committed to the client's goals, with a sincere involvement in their healing experience while establishing a mutual and meaningful relationship with our clients during their recovery process. This certainly remains a gold standard of practice to this day.

Jerry Johnson (1973) continued along these lines, which harkened back to the ideas of the founders, proclaiming that the knowledge base of occupational therapy was well suited to address both individual and societal needs. Johnson emphasized the need for occupational therapy to reexamine the profession's relationships with other professions to better adapt to a changing world. This included a concern over the closeness of the relationship of occupational therapy to medicine, stating that occupational therapy should look to market services outside of the hospital, including community health care centers, school systems, and day care centers. Advances in the behavioral sciences were seen as having tremendous potential for the enrichment of the profession and its practices, helping to address the feeling among some in the profession that it had become lost in the medical model during the rapid growth of the post–World War II era (Dasio, 1971). Josephine Moore (1976/2005) echoed this theme of integrating new knowledge from the behavioral sciences to better understand ourselves and our clients. In a similar vein, Lorna Jean King (1978/2005) expressed the belief that the knowledge regarding behavior should be integrated into a theory base specific to the understanding of adaptation and adaptive processes to meet the needs of the profession. The leaders of this time had a profound influence on the next generation of occupational therapy leaders and practitioners.

In 1977, Kielhofner and Burke's historical analysis characterized this rift with the conceptual model of medicine in terms of competing paradigms of professional thought. Theirs was probably the most comprehensive history of the profession written up to that time, looking at the first 60 years of the profession. The roots of occupational therapy were characterized as being largely humanistic but gravitating toward an increasingly reductionistic or mechanistic practice, focusing more on body parts and isolated functions than on larger sets of occupations and the meaning associated with engagement. This rift was characterized as creating a growing crisis in professional thought. Kielhofner and Burke (1977) discussed the need for the profession to continue to develop a paradigm of occupation that takes into account the active nature of the human adaptive process with attention to ongoing research concerning developmental and social theory. This need continues to be a focus of Gary Kielhofner's (2002) work in the form of the model of human occupation. Since publication of the first edition of his book in 1985, Kielhofner and his colleagues have been working to further the scientific understanding of the human need for occupation and its application to the practice of occupational therapy.

The model of human occupation has kept an eye on the past, striving for a holistic perspective in the endeavor to understand human occupation, while incorporating contemporary theories and concepts. The model of human occupation respects the past while incorporating current knowledge formations.

ONGOING GROWTH AND DEVELOPMENT OF THE PROFESSION AND ITS RELATIONSHIP TO HISTORY

The profession of occupational therapy has continued to develop in new directions, one influential innovation being the development of occupational science. Occupational science traces its roots back to the ideas of the founders, who believed that occupation and knowledge of its capacity to promote health and well-being may be used throughout the broader population to improve quality of life. Spearheaded by Elizabeth June Yerxa in 1989, the first occupational science program was developed at the University of Southern California with the intent to further understand the complexity of human occupation. Occupational science was developed with the intention of informing and providing inspiration for occupational therapy practice while attempting to look at occupation in new ways, infusing new concepts and ideas into the understanding of occupation (Clark, Wood, and Larson, 1998). This includes utilizing varied research approaches, including case studies that allow for more naturalistic inquiry and experience sampling methods, in addition to more standard research approaches such as randomized clinical trials.

Occupational science's unique focus on the broader issues of human occupation, rather than an exclusive focus on occupational therapy practice, has been designed to meet the goal of producing more powerful therapeutic interventions which can be utilized by occupational therapists in both traditional and innovative treatment settings (Clark et al., 2005). A prime example of this occupation-based intervention is the well-elderly study (Clark et al., 1997). This research project broke new ground in the world of occupational therapy, demonstrating that preventive occupational therapy could help to prevent the declines normally associated with aging. Out of this study came the concept of "lifestyle redesign." This new intervention relies on fundamental occupational therapy ideas and ongoing occupational science research and theory development that provide individualized intervention to help individuals construct more healthful life routines and foster more meaningful engagement, the end result being improved quality of life. For example, research is now being directed toward understanding how occupations influence the risk of pressure sores among those with spinal cord injury. Another application of lifestyle redesign

principles is in the area of weight loss. Using an occupational science perspective on the issues of weight gain and modulation of one's activity, the lifestyle redesign program to help individuals lose and control weight shows potential for being one way to address the growing public health concern about obesity in the United States. Just as those associated with the founding of occupational therapy hoped that knowledge of occupation would help to address the growing public health concerns about mental health at the dawn of the twentieth century, so do practitioners of occupational science hope to help occupational therapy address the growing public health concerns of the twenty-first century (Clark et al., 2005).

Evidenced-based practice is another recent and powerful development in society and in the profession of occupational therapy as the profession strives to hone its skills and understanding of the therapeutic value of our interventions (Holm, 2000). Although evidence-based practice might appear to be a new issue in many ways, it is truly an ideal that resonates with the founding of the profession. From the beginning of the profession, many physicians were able to see the beneficial effects of occupation on the recovery of their patients. Using the science of the time, they struggled to understand the mechanism of healing in those they served. Evidenced-based practice is closely related, being the vehicle of our own time to understand what are the most effective means of helping those whom we serve and understanding the means and pathways that our interventions help to produce gains in health and quality of life.

CONCLUSION

When one considers the history of the profession of occupational therapy, a number of consistent themes emerge. First, the profession has always had an altruistic mission, sought a scientific foundation for practice, and utilized the strength of its professional organization to establish itself as a true profession. Occupational therapy began during a unique time in which a dynamic integration of mind and body was at the forefront of the medical profession, and our profession continues to incorporate a therapeutic perspective in which mind and body are integrated in the concept of health and wellness. Occupational therapy was seen as having the potential to be an important contributor to society from its inception, and it continues to have a potentially powerful role in enhancing the lives of individuals throughout the life course.

PROVOCATIVE QUESTIONS

1. The social challenges of changing lifestyles and growing concerns over the general health of the population were important factors in the early conceptual development of occupational therapy. Has occupational therapy met the challenge of helping the general public to lead healthier lifestyles? How can we improve on our performance in this area?

2. At the dawn of the twentieth century, Americans were concerned that life was too fast paced, that people suffered from a lack of energy, and that lifestyle changes were necessary to address this growing concern. How would you compare the social issues and concerns of 100 years ago with those in our current cultural discussion?

3. The incorporation of scientific theory and ideas is a critical element of professional status for any profession. How is current knowledge development supporting our scientific understanding of occupational therapy? Do you feel that you have a strong scientific understanding of your own therapy practices?

Contemporary Occupational Therapy Practice in the United States

ELIZABETH BLESEDELL CREPEAU, BARBARA A. BOYT SCHELL, AND ELLEN S. COHN

"People are most true to their humanity when engaged in occupation."

—YERXA ET AL. (1989)

Learning Objectives

After reading this chapter, you will be able to:

1. Define occupational therapy.
2. Describe examples of the range of services provided in the United States.
3. Identify common core aspects of practice.
4. Consider possible futures for the profession.

◆ Linda is a 35-year-old carpenter who accidentally cut the tendons across the back of her right, dominant, hand at work. She lives with her partner, Susan, in a house surrounded by a garden to which they devote considerable time and energy. Robin, an occupational therapist, custom-made a hand splint for Linda that positions and protects her hand while it is healing. Robin also showed her how to manage her wound care as part of her daily self-care routine. Together they discussed what activities Linda could realistically and safely do, both at home and at work. Robin encouraged Linda to use the two fingers on her injured hand that

were not involved as much as possible and suggested that she might want to use the coming weeks to do the computer work needed to get her year-end taxes ready, since Linda owns her own business.

◆ Lauro is a 14-year-old junior high student with developmental disabilities. He has been successfully included in the public school setting, but he, his family, and his educational team must begin planning for his transition from school to life after graduation. At a recent educational-planning meeting Lauro stated that he would like to take the local bus with his peers to his weekly after-school sports program rather than driving with his mother each week. Lauro has never used public transportation and has little understanding of how to manage money. He is not sure what he would like to do when he grows up but knows he wants to live in his own apartment someday.

◆ Jack, Pete, and Harry like to attend the Bridges program at the local recreation center. Bridges is a member-directed program for people who are living with mental illness. This morning, the newspaper group discussed ideas for articles for the next monthly issue. Members selected topics and went to the recreation center's computer room to search the Web for ideas. When they arrived at the computer room, Sally, a certified occupational therapy assistant, helped each member set up a computer with the appropriate adaptations.

◆ Maplewood Industries is a furniture company whose employees have experienced many work-related repetitive trauma injuries. John, an occupational therapist, has a contract with Maplewood to conduct a work-site assessment to identify how the various workstations could be changed to avoid repetitive trauma injuries. He also has been working with the company health nurse to develop and implement an employee-training program to prevent the onset of these injuries.

◆ Mrs. Oak is a retired schoolteacher whose husband of 52 years died the past spring. She has just moved into a small apartment in a life-care community. Her daughter, who lives in another state, is concerned that her mother seems depressed and is not adjusting to her new setting, even though there are many activities there for her to enjoy. Pam, the occupational therapist, interviewed Mrs. Oak about her lifelong interests and activities and is helping Mrs. Oak adapt her routines to this setting.

◆ Mary works with the Mayor and City Council to help shape policies and funding priorities designed to make the town safer and easier for everyone to access public services and engage in healthy behaviors. As a result of her advocacy, there are now safe and well-lit walking paths with frequent resting places that senior citizens and families with young children are enjoying. Additionally sidewalks and bicycle paths within a one-mile radius of schools are monitored by school guards and volunteers to encourage children to walk or bike to school, thus the children are getting more exercise and

parents are saving time in transportation. Currently Mary is working on a grant with the recreation department director to obtain playground equipment designed to make it easier for children with mobility impairments to use the public playgrounds.

These six scenarios represent the diversity of occupational therapy intervention for occupational therapy clients, be they individuals, groups, organizations or populations. Linda wants to be able to return to work and her garden. Like most adolescents, Lauro wants to be more autonomous from his parents, use public transportation, live in his own apartment someday, and learn job skills to prepare him for life after high school. The members of the Bridges program want to be able to contribute to their group and the broader community and to enjoy time with their friends. The manager at Maplewood Industries wants to be sure that his employees do not develop repetitive trauma injuries because of his concern for them as human beings and for the company's productivity. Mrs. Oaks wants to find a way to live meaningfully in her new life, and her daughter wants her to be as comfortable as possible. Mary and the leaders of her community want a healthy population that is able to participate fully in public areas. As these scenarios demonstrate, occupational therapy practitioners provide services to a variety of clients in many settings, from hospitals and schools to community programs and businesses. These services include direct intervention with individuals to programming for groups to consultation within organizations and public advocacy. In all cases, the overarching goal of occupational therapy is to engage people in meaningful and important occupations to support health and to participate as fully as possible in society.

DEFINITION OF OCCUPATIONAL THERAPY

Occupational therapy is the art and science of helping people do the day-to-day activities that are important and meaningful to their health and well-being through engagement in valued occupations. The *occupation* in occupational therapy comes from an older use of the word, meaning how people use or "occupy" their time. Hasselkus (2006) in her Slagle lecture spoke about everyday occupation as something that is so ordinary and embedded in the everyday that we may fail to appreciate its complexity and how our occupations constitute an interwoven network of all we do on a daily basis. Occupational therapy, drawing on the centrality of occupation to daily life, refers to all of the activities that occupy people's time, construct identity through doing, and provide meaning (Christiansen, 1999, Zemke, 2004). Occupation includes the complex network of day-to-day activities that enable people to sustain their health, to meet their needs, to contribute to the life of their family, and to participate in the broader society (American Occupational Therapy Association [AOTA], in press).

Finally, occupational engagement is important because it has the capacity to contribute to health and well-being (Clark et al., 1997; Glass, Mendes de Leon, Marottoli, & Berkman, 1999; Law, Seinwender, & Leclair, 1998). As the scenarios that opened this chapter illustrate, occupational therapy practitioners provide individual or group intervention as well as consultative services that foster community participation, prevention, and wellness of groups in a wide range of settings. The desired outcome of occupational therapy intervention is that people will live their lives engaged in occupations that sustain themselves, support their health, and foster involvement with others in their social world.

Contemporary occupational therapy practice draws on the historical roots of the profession, filtered through current occupational therapy, health, and human service research and practice. Meyer (1977/1922), for example, in his oft-quoted address to the National Society for the Promotion of Occupational Therapy asserted, "Our role consists in giving opportunities rather than prescriptions. There must be opportunities to work, opportunities to do, to plan and create, and to use material" (p. 641). Englehardt (1977), and more recently Pörn (1993), asserted that health is measured by an individual's adaptive capacity and engagement in daily activities. In her Eleanor Clarke Slagle Lecture, Yerxa (1967) explained that authentic occupational therapy focuses on clients' humanity and their ability to choose and initiate activities that provide the basis for the discovery of meaning. She further argued that authentic occupational therapy requires that the practitioner "in every professional act defines the profession" and, in doing so, enters into a reciprocal relationship characterized by mutual care and that "to care means to be affected just as surely as it means to affect" (p. 8). Later in her address, Yerxa called for practitioner engagement in research to promote the development of the knowledge base of the profession. These themes translate into three principles to guide contemporary occupational therapy:

1. Client-centered practice
2. Occupation-centered practice
3. Evidence-based practice

CLIENT-CENTERED PRACTICE

At the core of occupational therapy is the commitment to focus on the client as an active agent seeking to accomplish important day-to-day activities. Occupational therapy practitioners often work with people who are disempowered (Kronenberg & Pollard, 2005; Townsend, 1996). Clients seek care and professional help to "gain mastery over their affairs" (Rappaport, 1987, p. 122). To be client centered, practitioners must be willing to enter the client's world to create a relationship that encourages the other to enhance his or her life in ways that are most meaningful to that person. Practitioners strive to understand the client as a person embedded in a particular context consisting of family and friends, socioeconomic status, culture, etc.

In a client-centered model, practitioner and client collaboratively engage in the therapeutic process (Law, 1998). Mattingly (1991) asserted that this process is narrative in nature, which means the practitioner and client create an understanding of the client's past, present, and future story. Mattingly further asserted that the future story is co-constructed and constantly revised in the midst of therapy. Practitioners strive to understand human feelings and intentions as well as the deeper meaning of people's lives through what Clark (1993) called occupational storytelling. In contrast, occupational storymaking occurs in the midst of therapy. It is that imaginative process through which clients create and then enact new occupational identities (Clark, 1993).

OCCUPATION-CENTERED PRACTICE

Contemporary occupational therapy emphasizes occupational engagement. Clients seek occupational therapy because they need help engaging in their valued occupations. The emphasis on occupational engagement stems from the profession's beliefs, substantiated by emerging research, that people's occupations are central to their identity and that they can reconstruct themselves through their occupations (Jackson, 1998). Occupations are not isolated activities but are connected in a web of daily activities that help people fulfill their basic needs and contribute to their family, friends, and broader community (Hasselkus, 2006). Occupation-centered practice focuses on meaningful occupations selected by clients and performed in their typical settings (Fisher, 1998; Pierce, 1998). Systematic assessment of clients' occupations and priorities are vital to occupation-centered practice. This information—when coupled with careful analyses of the person's capacities, the task's demands, and the performance context—provides the basis for intervention. Intervention goals are directly connected to the person's occupational concerns, and intervention methods capitalize on the person's occupational interests. In this way, both the means (methods) and the ends (goals) of therapy involve intervention grounded in the occupations of the client (Fisher, 1998; Gray, 1998; Trombly, 1995).

Consistent with client-centered and occupation-based practice, Ann Wilcock and Elizabeth Townsend, leaders in occupational therapy from two different part of the world, introduced the concept of occupational justice to acknowledge that all people are occupational beings and that meeting all peoples' need for engagement in meaningful occupation is a matter of justice (see Chapter 20). Wilcock and Townsend equate occupational justice with rights, equity, and fairness and argue that every individual has the right to have equal opportunities and access. To address

injustices, occupational therapy practitioners have begun to develop interventions and advocate for people who are disempowered by legislation, war, political upheavals, dictatorships or natural disasters. While many of the occupational therapy initiatives to address instances of occupational injustice have been developed in other parts of the world, practitioners in the United States have begun to embrace the ideals of an "occupationally just" world and develop interventions with these goals in mind.

EVIDENCE-BASED PRACTICE

One of the important trends in health care is the growing requirement to base intervention decisions on "the conscientious, explicit, and judicious use of current best evidence" (Sackett, Rosenberg, Muir Grany, Haynes, & Richardson, 1996, p. 71). This process, called evidence-based practice, entails being able to integrate research evidence into the clinical-reasoning process to explain the rationale behind interventions and predict probable outcomes—or, as Gray asserted, "doing the right things right" (cited in Holm, 2000, p. 576). Beyond "doing the right things right," evidence-based practice involves being able to explain occupational therapy recommendations to clients in a language clients will understand (Tickle-Degnen, 2000). Furthermore, intervention grounded in the customs of the field no longer meets the ethical requirement to "fully inform the service recipients of the nature, risks, and potential outcomes of any interventions" (American Occupational Therapy Association [AOTA], 2000, p. 614).

The challenge for occupational therapy practitioners is threefold.

◆ First, to practice occupational therapy based on research evidence, practitioners must know how to access, evaluate, and interpret relevant research.
◆ Second, practitioners must have the capacity to collect data to support their intervention recommendations.
◆ Third, once practitioners understand the possible interventions and related outcomes, they need to communicate the probable outcomes to clients and/or their care providers, so clients can decide whether to participate in occupational therapy intervention.

Not only must practitioners be willing to examine intervention practices to see if they are effective but also they must be open to changes in their intervention patterns when the evidence suggests more effective approaches than the ones they typically use.

OCCUPATIONAL THERAPY PRACTITIONERS

Clients are, of course, an essential component of occupational therapy intervention, but occupational therapy practitioners are the other part of the equation. Practitioners use their professional reasoning abilities to actualize their knowledge and skills in practice. Just as clients have an occupational history, so do practitioners. They are also embedded in personal, social, and cultural contexts that shape their worldview. These include their preferred theories and intervention techniques, the practical realities of the setting in which they practice, and the team members with whom they work (Schell, 2007).

Like clients, practitioners come with particular strengths and limitations that influence their interactions with others. These strengths and limitations influence how practitioners frame client problems and use the intervention context to benefit clients.

VISION FOR THE FUTURE

In 2017 the American Occupational Therapy Association will celebrate its 100th Anniversary. In recognition of this milestone, the AOTA spent several years in an extensive visioning process, designed to guide the profession toward maximizing its potential to be of service to society. The Centennial Vision was approved by the AOTA Representative Assembly at the 2006 annual conference. The vision statement states:

> We envision that occupational therapy is a powerful, widely recognized, science-driven and evidence-based profession with a globally connected and diverse workforce meeting society's occupational needs. (AOTA, 2006)

The Centennial Vision lists key points to achieve this vision by 2017. These elements address the preparation and diversity of the occupational therapy workforce so that it is more visible, powerful and able to collaborate with others to improve the health and well-being of individuals and the broader society. In addition, our leaders envision greater innovation based on science to guide practice and to provide the evidence to support occupational therapy intervention. Finally, membership in AOTA will be seen as a professional responsibility because it is through a strong member involvement that the potential of occupational therapy to meet society's occupational needs will become a reality (AOTA, 2006). In her Farewell Presidential Address Carolyn Baum, AOTA president from 2004–2007, said:

> Those who founded our profession had a vision: that occupational therapy would study and use occupation as it influences health, and would educate people about its value. Many, many advances are making our founders' vision a reality. As we get closer to the actual Centennial celebration, it is a time for occupational therapists and occupational therapy assistants to seize the opportunities of those changes in the health care system that place value on health and par-

ticipation. We must use our knowledge and skills to be very visible with our contributions, which improve the quality of the lives of those we serve. (Baum, 2007)

CONCLUSION

Occupational therapy is a complex process that involves collaborative interaction between the practitioner and the client embedded in the intervention context. Occupational therapy intervention must be grounded in research and focused on the client as an occupational being. The therapeutic process evolves as the practitioner and client work together to analyze carefully the client's occupations and performance limitations. Because occupational therapy is a "doing with" and not a "doing to" profession, there is an improvisational aspect of intervention that requires the practitioner and client to coordinate their actions to achieve the client's goal. The rest of this book delineates the various aspects of occupational therapy. It emphasizes consistently that best practice involves (1) understanding and respecting clients, (2) collaborating with clients to achieve their occupational goals, and (3) using interventions that are supported by research.

As you start your career, our challenge to you is to strive to achieve the ideals of the profession. First, be aware of the influence of your beliefs and your personal and professional contexts and how these influence your actions. Second, consistently challenge yourself to listen to your clients so that you can facilitate their autonomy and engagement in desired occupations. Third, use the most effective assessment instruments and interventions to support the progress of your clients. Fourth, advocate for your clients so they can obtain the services they need and learn to advocate for themselves. Finally, systematically evaluate your practice to ensure that your interventions enable your clients to engage in those occupations they value most. The people whose scenarios opened this chapter remind us that we have the responsibility to live up to the ideals of the profession. Peloquin, one of our philosophers, concluded her 2005 Eleanor Clarke Slagle with the following statement:

> The ethos of occupational therapy restores our clearsightedness so that we see what is essential: We are pathfinders. We enable occupations that heal. We cocreate daily lives. We reach for hearts as well as hands. We are artists and scientists at once. If we discern this in ourselves, if we act on this understanding everyday, we will advance into the future embracing our ethos of engagement. And we will have reclaimed our magnificent heart. (2005, p. 623)

We welcome you to the path of occupational therapy.

Contemporary Occupational Therapy Practice Worldwide

23

TERRY K. CROWE

Learning Objectives

After reading this chapter, you will be able to:

1. Review the historical development of the World Federation of Occupational Therapists (WFOT)
2. Recognize the functions and structure of WFOT
3. View the diversity of professional practice and entry-level occupational therapy education through a world lens
4. Understand requirements and opportunities for international work
5. Reflect about the future trends of occupational therapy internationally

A s the world becomes "smaller" through communication connections and globalization influences, we can learn from the occupational therapy perspectives and activities at a world level. This chapter focuses on the growth and future trends of occupational therapy internationally.

HISTORICAL OVERVIEW

In 1952, the World Federation of Occupational Therapists (WFOT) was created (Spackman, 1967). WFOT is the key international representative for occupational therapy and the official international organization for the promotion of occupational therapy (World Federation of Occupational Therapists, 2006a). The founding members of WFOT were Australia, Canada, Denmark, Great Britain (England and Scotland), India, Israel, New Zealand, South Africa, Sweden, and the United States (Spackman, 1967). Helen Willard and Clare Spackman were part of the original WFOT

leaders (Mendez, 1986). Spackman became the first WFOT delegate from the American Occupational Therapy Association (AOTA) and went on to become the WFOT president from 1959 to 1961.

WFOT Congresses

Only two years after WFOT was founded, the first WFOT Congress was held in Edinburgh, Scotland. It was attended by almost 400 participants from 21 countries (Paterson, 1994). The conference themes reflected the major areas of occupational therapy at that time: tuberculosis, poliomyelitis, psychiatry, cerebral palsy, and rehabilitation and resettlement. The international issues facing the profession were summarized as an inadequate number of educational programs; a shortage of occupational therapists; lack of governmental, medical, and civil support; and the lack of unification of educational standards and terms of service. The WFOT Congresses continue to be held every four years, bringing together occupational therapists from around the world. At the 14th Congress in Australia, in 2006, over 2,000 occupational therapists from 80 nations learned from each other (Crowe, 2006a). The next Congress will be held in Santiago, Chile, in 2010.

WFOT Organization

WFOT comprises 66 organizational members, 10 associate members, and over 6,000 individual members, 2,038 of whom are from the United States (Table 23.1) (Evert & Cronin, 2007; World Federation of Occupational Ther-

apists, 2006b). WFOT is structured in five main program areas: education and research, promotion and development, standards and quality, international cooperation, and the executive program (World Federation of Occupational Therapists, 2006c). Specific projects within these programs are undertaken by occupational therapists from around the world. The federation is managed by volunteer leadership using a virtual office. AOTA elects three individuals to represent the United States in the World Federation (American Occupational Therapy Association, 2005). The delegate is the voting member at the WFOT Council meetings. The first alternate delegate sits in the Representative Assembly to represent AOTA members who practice in foreign countries. The second alternate delegate acts as a liaison helping therapists who would like to work temporarily or permanently in other countries. All three delegates plan and implement the International Day at the AOTA Annual Conference.

GLOBAL GROWTH IN OCCUPATIONAL THERAPY

Occupational therapy continues to expand worldwide. For example, professionals in Georgia, a former Soviet Republic that has a population of 4.7 million people (World Factbook, 2006), recognized the need to develop occupational therapy in 2001 (World Federation of Occupational Therapists, 2005a). With help from the European Network of Occupational Therapy, eight Georgian students were

TABLE 23.1   WFOT MEMBERSHIP CATEGORIES

Category	Requirements
Full Country Membership	◆ Have an occupational therapy association with an approved constitution ◆ Have at least one WFOT approved entry-level educational program ◆ Can vote on WFOT agenda items ◆ 66 WFOT Member nations
Associate Country Membership	◆ An occupational therapy association with an approved constitution ◆ Cannot vote on WFOT agenda items ◆ 10 WFOT Associate Member Countries
Individual Membership	◆ Open to Occupational Therapy and Occupational Therapy assistants who are members of their country professional Occupational Therapy association (i.e. AOTA) ◆ Dues paid to WFOT through national association ◆ Receive WFOT Bulletin ◆ Access to member only aspects of WFOT webpage ◆ Eligible for WFOT Research Awards ◆ Can participate in WFOT Project Teams ◆ 6,749 individual members ◆ Of this, 2,038 are from the United States + 490 student members

[From World Federation of Occupational Therapists (2006d).]

locally educated and graduated in 2004, and the Georgian Occupational Therapy Association was formed. Practice areas in Georgia and other former Soviet Republic countries include integrating children and adults into the community and upgrading the intervention that is provided to people who reside in institutions. In 2006, Georgia became a member of WFOT. Similarly, assisted by WFOT, Egypt, which has 78.9 million residents (World Factbook, 2006), plans to develop occupational therapy education programs in three Egyptian universities (World Federation of Occupational Therapists, 2005e).

EDUCATION OF OCCUPATIONAL THERAPISTS WORLDWIDE

Education of occupational therapists at the international level is critical to the advancement and global expansion of occupational therapy worldwide (Figure 23.1). Many of these educational programs are guided by the educational standards set by WFOT. The first WFOT Educational Minimal Standards were published in 1958 (Hockings & Ness, 2002). The 2002 Revised WFOT Minimum Standards are visionary and address the challenge of making higher education relevant to each country's cultural uniqueness, social and economic structure, and prevailing health needs and priorities (Hockings & Ness, 2004a). These standards highlight the centrality of occupation, the realization of cultural differences in occupation and health care practice, and the power of occupation in building healthy communities. They emphasize that educational programs need to disseminate local as well as international knowledge related to the profession. The local context refers to the geographical area of the country, the characteristics of health and welfare needs and systems,

FIGURE 23.1 Occupational therapy students in Mexico City facilitate participation in a home for elderly people.

and the diversity of cultural backgrounds. The AOTA Educational Standards meet or exceed the WFOT Educational Minimal Standards (American Occupational Therapy Association, 1998).

Currently, WFOT recognizes 566 occupational therapy educational programs (World Federation of Occupational Therapists, 2006e). Internationally, there are numerous other occupational therapy educational programs that teach occupational therapy but that have not been reviewed or approved by WFOT. Educational programs for occupational therapy vary widely in their intensity and level of content. The minimum requirement recommended by WFOT for occupational therapy education is 90 weeks (Hocking & Ness, 2004b). Educational programs may be housed in universities, colleges, private institutions, or medical facilities. Students may graduate at a certificate, diploma, undergraduate, or graduate degree levels. The United States and Canada have the highest educational degree requirement: Entry-level occupational therapists must have a master's degree (American Occupational Therapy Association, 1998; Canadian Association of Occupational Therapists, 2005). Only the United States, the United Kingdom, and South Africa have recognized educational programs for occupational therapy assistants (American Occupational Therapy Association, 1998; British Association/College of Occupational Therapist, 2006; Van der Reyden, 2005).

WORKING INTERNATIONALLY

Occupational therapists can work in other countries if they meet the requirements of the specific country. Many countries will employ occupational therapists only if they have graduated from a WFOT-approved school (World Federation of Occupational Therapists, 2007). A great way to connect with international occupational therapy work and volunteer opportunities is through the Occupational Therapy International Outreach Network (OTION), a forum for information exchange (Newton & Fuller, 2005). OTION's goal is to form partnerships between occupational therapists in resource-rich countries and organizations serving people with disabilities in resource-poor countries. There are many pathways to working internationally, including volunteering with the Peace Corps (Crowe, 2005a, 2007), working with an international nongovernmental organization, volunteering short or long term (Crowe, 2005b, 2005c, 2006b), or working in a facility that provides occupational therapy.

COUNTRY PROFILES

Although occupational therapy is now a worldwide profession, the nature of practice is shaped to meet the different cultures and resources within each country. Table 23.2 provides brief profiles of the practice of occupational therapy

◆ Actively promote and facilitate the development of excellence in the profession in all areas of practice ◆ Be an efficient, effective and financially viable organization through excellence in practice ◆ Maximize the relevance, effectiveness and profile of OT AUSTRALIA through quality professional representation and marketing activities/initiatives (M. Pattison, personal communication, Oct. 13, 2006)	systems and assure greater OT participation ◆ Continue working in cooperation with different organizations, groups and other professional associations to develop greater civic participation ◆ Advance the professional certification to a national level to assure high quality Occupational Therapy interventions ◆ Enhance the continuous specialization and training of occupational therapists (E. Henny and O. Castro, personal communication, Dec. 16, 2006)	governmental and non-governmental organizations ◆ Increase occupational therapy research ◆ Assure that the Indian Council of Occupational Therapy govern the profession in respect to occupational therapy education and practice ◆ Increase community-based and evidence-based occupational therapy (A. Srivastava, personal communication, Nov. 21, 2006)	(S. Shann, personal communication, Nov. 9, 2006)	efficient service delivery ◆ Increase the role for Occupational Therapy in vocational rehabilitation and employment ◆ Assure that occupation is central to service delivery ◆ Create more roles for occupational therapists related to health promotion and public health (B. Steeden, personal communication, Oct. 13, 2006)

on each of the five world continents. One country is highlighted on each continent. Notice that very different health issues face each country. The WFOT Website provides similar information on many countries in the world.

FUTURE OF OCCUPATIONAL THERAPY WORLDWIDE

Since only 76 of the world's 271 nations and other recognized territories have established practices in occupational therapy as acknowledged by WFOT, a significant amount of growth is needed for occupational therapy to reach the world's estimated 6 billion, 538 million people (U.S. and World Population Clocks, 2007). For example, in Bangladesh, a country of 147 million people (World Factbook, 2006), in 2005, there were only 25 locally trained occupational therapists and two occupational therapists who had been trained in other countries (Newton & Fuller, 2005). Other countries, such as Cambodia, Vietnam, and Bermuda, do not have any locally trained occupational therapists (Crowe, 2005c; M. Patterson, personal communication, August 26, 2005), although there may be some foreign occupational therapists working on special projects or local therapists who have been educated outside of their country (Figure 23.2). Many countries around the world provide opportunities to develop occupational therapy that is culturally relevant. Occupational therapy needs to be contextualized and acknowledge traditional and cultural beliefs around health, illness, and disability. This offers occupational therapists a chance to develop innovative practice and educational models to assist people around the world to have occupationally rich lives.

An inspiring development in occupational therapy on the world stage is the involvement in community-based rehabilitation, an approach that is used primarily in countries with limited resources (Fransen, 2005; Sinclair, Sakellariou, Kronenberg, Fransen & Pollard, 2006). Professionals including occupational therapists implement rehabilitation at a community level, attempting to equalize opportunities and promote social integration of people with disabilities (Figure 23.3). Human rights are an issue even in countries with established occupational therapy services where many marginalized people are not able to access services. Examples are people without health insurance, refugees, survivors of violence, indigenous people, or people who are homeless (Algado & Burgman, 2005; Algado & Cardona, 2005; Davis & Kutter, 1998; Kronenberg, 2005; Petrenchik, 2006; Simmond, 2005). Challenges include tremendous personal, occupational, and environmental adversity. Occupational therapy needs to expand service delivery models to meet these challenges and to embrace more people internationally. Peloquin (2005) ele-
FIGURE 23.3 A child with an autism spectrum disorder participates in an elephant camp implemented by occupational therapists in Thailand. Through carefully monitored interactions with the elephants, the outcomes include higher levels of adaptive responses and social/communication abilities in the children.

FIGURE 23.2 The author works with a child and her mother while consulting with a visiting nurse in a Cambodian village.

? PRACTICE DILEMMA

PROVIDING SERVICES IN ANOTHER COUNTRY

You have volunteered to work in an educational program for children with disabilities in Oaxaca City, Oaxaca, Mexico. Oaxaca has only a handful of occupational therapists, mostly working in a nearby government rehabilitation hospital. You speak intermediate-level Spanish. You have graduated from an educational program approved by the American Association of Occupational Therapy (AOTA).

1. Can you practice in Mexico without any additional qualifications? How do you know?
2. Since you are not fluent in Spanish, how will you understand a family's occupational needs and views of health, illness, and disability? How will you develop occupational priorities for children that are specifically relevant to the children and their families within their cultural context?

---

gantly states: "Through the use of empowering occupations, our therapy programs transform settings. In a world grown small because of easier travel and widespread media coverage, those who are poor, disenfranchised, socially isolated and marginally cared for beckon to us (as occupational therapists) as they have never done before" (p. 101). It is the responsibility of all of us to promote the participation of people with disabilities in all countries.

SUMMARY

Occupational therapy has expanded widely throughout the world since its beginning in 1917. With the currently increasing global professional networking and international collaboration, occupational therapists will be spearheading international cooperative efforts to improve responses to natural and human-made disasters, improve the health and well-bring of all worldwide citizens, and provide meaningful occupations to all. In the next decade, we will see many countries joining WFOT. In addition, occupational therapy will strengthen its role and continue to expand service delivery approaches to meet the needs of more people on an international level. Yerxa (2003) stated that "occupational therapy is committed to improving the life opportunities, health and capability of all people, including those with chronic impairments by employing occupation as therapy, contributing new knowledge of occupation to society, and

by influencing public policy for people" (p. 976). This needs to take place internationally so that people with occupational challenges can lead more meaningful lives.

Occupational Therapy Professional Organizations

SARA BRAYMAN

Learning Objectives

After reading this chapter, you will be able to:

1. Describe the roles of AOTA, NBCOT, and state regulatory boards in the credentialing of occupational therapy practitioners in the United States.
2. Appreciate the roles that both volunteer and paid staff members in professional organizations play in developing and supporting all aspects of the profession and its members.
3. Understand how professional and regulatory organizations serve the consumers of occupational therapy through standard setting and education.

Occupational therapy students, occupational therapy assistants, and occupational therapists are, by virtue of their education, license, and/or certification, eligible to be members of the occupational therapy profession. The formation of professional identity is a developmental process that begins at the point at which an individual chooses occupational therapy. It builds while he or she is in school, beginning to learn the theories, techniques, and procedures of practice. This developmental process does not cease when the individual graduates and enters practice but continues to develop throughout his or her professional life. Being a professional requires that an individual recognize and adhere to that profession's code of ethics, practice within its defined scope, and contribute to the evolving development of knowledge and skills that are necessary to continually refine that profession. The entire process is supported by professional organizations that set standards and provide support to individuals and the profession as a whole. The following Case Study provides an example that illustrates the various organizations that support the entry into the profession of occupational therapy. As you read this chapter, refer back to this case.

Kanesha is a senior in high school. She has just discovered that she would like to be an occupational therapist who works with children with special needs. She learned about occupational therapy (OT) from a video and a presentation by OT students during a career fair at her school. The students invited her to come to the university, sit in on a class, and meet some of the professors. They also suggested that she visit the Website of the American Occupational Therapy Association (AOTA) to learn more about OT. Perusing the Website only served to heighten Kanesha's interest in OT, so she made arrangements to visit the university and to speak with one of the OT faculty members. She completed the application process and was accepted into the freshman class as a pre-occupational therapy student. She worked hard to maintain a good grade point average and was careful to take all of the courses needed to enter the OT program.

Kanesha was very excited when she was accepted to the program. Her first courses were very challenging, and she was pleased to learn more about her chosen profession. She joined AOTA as a student member and became increasingly interested in all of the different areas in which occupational therapists practice. She took advantage of one of the benefits of belonging to AOTA as a student member. She found that the *American Journal of Occupational Therapy, OT Practice,* and the Special Interest Section Quarterlies contained interesting articles that were relevant to her coursework. Additionally, she used the OT Search through the AOTA's Website to quickly find OT resources for research papers.

While completing her coursework, Kanesha and her clinical fieldwork coordinator worked together to find a Level II fieldwork site in Florida so that she could complete the last of her fieldwork while living with her grandparents. Using the AOTA e-mail list, her coordinator found other fieldwork coordinators in Florida and was able to locate an appropriate fieldwork placement. During her final Level II fieldwork placement, Kanesha contacted the National Board for Certification of Occupational Therapists (NBCOT®) and applied to take her certification examination after completing her fieldwork. She could take the examination at a site that was close to her home. During this time, she studied by reviewing information from her textbooks and from the portfolio of all of her course work. She was glad that she had studied because the examination was rigorous.

Kanesha began to answer advertisements for occupational therapists. She interviewed at several places and finally narrowed her choices down to a position in South Carolina and another closer to home in Texas. Because she was not sure which of the positions she would accept, she contacted the state regulatory boards in both states to apply for licensure. She asked NBCOT to send her examination results to both of them. She anxiously awaited word from NBCOT and, after a couple of weeks, was thrilled to learn that she had passed the examination and was now a registered occupational therapist. She accepted the offer from a private practice group in Texas and began her new job working with children with autism. There was so much to learn! When her student membership expired, she renewed her AOTA membership and joined both the Developmental Disabilities and the School System Special Interest Sections so that she could communicate with other occupational therapists who worked with this population. Kanesha welcomed the information and resources provided by these therapists and by her supervisor and coworkers. She joined the Texas Occupational Therapy Association so that she would get to know other OTs in her state and become an active part of her profession.

This chapter introduces the reader to the major professional occupational therapy organizations in the United States. Because many of the profession's major standards and policies are developed by the American Occupational Therapy Association, much of this chapter focuses on the various components of that organization. State and international organizations and legal entities that affect occupational therapy are also briefly discussed, including how the AOTA relates to the World Federation of Occupational Therapy, which was discussed in Chapter 23.

AMERICAN OCCUPATIONAL THERAPY ASSOCIATION

American Occupational Therapy Association (AOTA) is the member organization in the United States that is responsible for guiding and developing occupational therapy's standards and code of ethics and for defining the profession's scope of practice. It was incorporated in New York in 1917 as the Society for the Promotion of Occupational Therapy. Its name was changed in 1927 to the American Occupational Therapy Association. Its membership comprises individual occupational therapists, occupational therapy assistants (OTAs), and students from all areas of practice. The members develop and refine AOTA's mission, education and practice standards, and code of ethics, all of which shape the profession. This is accomplished by individual members working together as volunteers serving on association committees.

The volunteer leaders as well as the members of the association are supported by staff employed by AOTA. The staff is supervised by the AOTA Executive Director, who in turn is supervised by the AOTA Board of Directors. Because most of the profession's policies, resources and standards are developed by volunteers, it is helpful to under-

stand the many leaders and groups within the association. Table 24.1 provides a summary of the key volunteer offices and groups within AOTA. Table 24.2 summarizes some of the common acronyms that are used to refer to related groups.

AOTA Officers and Directors

AOTA has four officers: the president, vice president, secretary, and treasurer. The president presides over the Board of Directors (BOD) and the annual business meeting and is the primary spokesperson of the profession. The vice president's primary responsibility is to guide the development and direction of the strategic and long-range plans of the association. For example, in recent years, the AOTA president and vice president led the association in defining a vision of where the profession should be by the year 2017. The secretary is responsible for keeping the official minutes and documents of the association, and the treasurer has the responsibility for guiding the budgetary processes.

TABLE 24.1	**LEADERSHIP ROLES AND FUNCTIONS IN AOTA**	
Leadership Role	**Function**	**How Elected or Appointed**
AOTA officers ◆ President ◆ Vice president ◆ Secretary ◆ Treasurer	Lead the association	Elected by all AOTA members.
Board of Directors ◆ AOTA officers ◆ Speaker of the Representative Assembly ◆ Directors (OT/OTA) ◆ Public advisor ◆ Consumer advisor	Provide oversight to organization; legally responsible for association actions and finances	Elected by all AOTA members except the consumer member, who is appointed by the president.
Representative Assembly ◆ Representatives from states/election areas ◆ Chairs of Commissions ◆ Chair of Special Interest Section Standing Committee ◆ Delegate from Affiliated State Association Presidents ◆ Delegate from the Assembly of Student Delegates ◆ OTA delegate ◆ Delegate for therapists residing in foreign countries	Make and approve policies guiding the organization and profession	Representatives elected by state/election area AOTA members. Students elect student delegates.
Commissions ◆ Commission on Practice ◆ Commission on Standards and Ethics ◆ Commission on Education ◆ Commission on Continuing Competence and Professional Development	Develop guidelines and respond to issues related to practice Address issues related to ethics and professional standards Develop guidelines and respond to issues related to education Develop guidelines and respond to issues related to advanced competency	Chair elected by all AOTA members. Commission members appointed or designated per AOTA policy.
Affiliated State Association Presidents	Coordinate activities of state occupational therapy organizations	Chair elected by state association presidents.

TABLE 24.2   COMMON ACRONYMS FOR AOTA-RELATED GROUPS

ACOTE	Accreditation Council for Occupational Therapy Education
AOTF	American Occupational Therapy Foundation
ASAP	Affiliated State Association Presidents
ASD	Assembly of Student Delegates
AOTA	The American Occupational Therapy Association, Inc.
BOD	The Board of Directors
CCCPD	Commission on Continuing Competence and Professional Development
COE	Commission on Education
COP	Commission on Practice
NBCOT	National Board for Certification in Occupational Therapy
OT	Occupational Therapist
OTA	Occupational Therapy Assistant
RA	Representative Assembly
SCB	Specialty Certification Board
SEC	Commission on Standards and Ethics
SIS	Special Interest Section
WFOT	World Federation of Occupational Therapists.

Adapted from American Occupational Therapy Association. (2004). *The reference manual of the official documents* (10th ed.). Bethesda: Author.

The BOD has the financial responsibility for the association and is legally responsible for the actions of AOTA. In between meetings, business is conducted online or via telephone conference call. The president often invites others to serve as resources to the BOD so that many points of view are considered. Those individuals cannot vote but may enter into the discussions.

Representative Assembly

The largest body of AOTA, the Representative Assembly (RA), makes the policies that govern the association. The RA meets face to face each spring at the AOTA Annual Conference and Exposition and also conducts business in an online meeting each fall. Every faction of the membership is represented in this legislative body. Each representative is elected either nationally or by the AOTA members who reside in the particular state or jurisdiction. Before these meetings, the representatives seek input from their members about important policy decisions facing the profession. Issues such the move from a bachelor's degree to a graduate degree requirement for professional entry had to be approved by the assembly. Practice standards in general, as well as statements about the role of occupational therapy in various specialty areas, such as driving and neonatal intensive care, are ultimately approved by this group. (See Box 24.1 for a look behind the scenes about the controversy that sometimes occurs in the process of setting policy.) Each representative serves for a term of three years, and terms are staggered on a rotational basis to ensure continuity. Representatives elect leaders within the group to guide the business of the assembly.

Commissions

There are four commissions in AOTA: Practice, Education, Standards and Ethics, and Continuing Competency and Professional Development. The chair of each is a member of the RA. Each commission serves a major role in shaping the profession's identity. The chair of each commission appoints individuals to serve on the commission, selecting AOTA members who represent various areas of expertise and geographic diversity. The number of individuals on each commission varies. Each commissioner is a voting member of the RA.

Commission on Practice (COP)

This commission is charged with developing standards and other documents such as position papers, roles and functions papers, practice guidelines, and white papers that are related to and define the practice of occupational therapy. For example, the Standards of Practice for Occupational Therapy serves to define the profession by describing how occupational therapists respond to referrals, screen and evaluate their clients, plan and execute intervention, transition the client to other needed services, and discontinue services when appropriate. Also included is the practice related to education and certification credentials needed (AOTA 2005).

Commission on Education (COE)

This commission generates education-related policy recommendations to the RA for deliberation. For example, this commission has defined the role competencies for faculty teaching in occupational therapy programs, such as the one Kanesha attended (see the preceding Case Study). COE identifies, analyzes, and anticipates issues related to education in conjunction with the Education Special Interest Section.

Commission on Standards and Ethics (SEC)

This commission develops the association's code of ethics and recommends standards and ethics for the profession.

BEHIND THE SCENES

When you read a chapter such as this, it might seem that all these organizations and the policies that they promote "just happen." Nothing could be farther from the truth. Not only is there a great deal of work by volunteers and staff alike, there is also a lot of discussion, negotiation, and sometimes professional tension that occur in the making of policies and standards. One of the best ways to see this is to watch the discussions of the RA in action. Hotly contested topics over the years have included the following:

◆ Whether AOTA should support state licensure of occupational therapists: Many therapists thought that it would be better to maintain a national certification so that therapists would not be hampered when moving from state to state. However, over time, the argument for becoming licensed won, as therapists wanted legal standing in their states. Until therapists were licensed in their states, anyone could say that her or she was an occupational therapist, whether the person had the professional credentials or not.

◆ Whether the educational level for occupational therapists should move from bachelor's to master's level: This discussion went on for over 20 years, until the move was made to postgraduate entry for occupational

therapists. Those who were against the move were concerned that it would reduce the number of therapists, thus making access to services even more of a problem during times of shortage. Those who supported the move thought that many programs were requiring so many credit hours that it was like getting a postgraduate education without the degree. Although occupational therapists now must enter at the master's level, the dialogue about the appropriate standards and role of the occupational therapy doctorate is front and center while this book is being written.

◆ The scope of occupational therapy: A perennial concern is related to guidelines for what sorts of evaluations and interventions are "really occupational therapy" and what ones go beyond the scope of practice. For example, one question was whether it is appropriate for occupational therapists to utilize physical agent modalities or complementary and alternative interventions in their practice.

◆ The role of the Certified Occupational Therapy Assistant (COTA): Although AOTA policies are pretty clear that the COTA functions under the supervision of a registered occupational therapist (OTR), the exact nature of that supervision is frequently reexamined as practice evolves and new arenas emerge.

It serves as an oversight body related to complaints about unethical practice of members.

Commission on Continued Competency and Professional Development (CCCPD)

This commission's role is to develop the criteria and certification examinations for advanced areas of practice. It recommends standards for continuing competence and develops strategies for communicating information to stakeholders about issues of continuing competence and competency affecting occupational therapy. The CCCPD also develops tools to assist members in the development and implementation of continuing competence plans.

Special Interest Sections

In addition to the four commissions, there is a network of AOTA members representing eleven special interest sections. The special interest sections (SIS) are designed

to respond to practice needs by focusing on a specific component of practice, at the same time recognizing that all occupational therapy personnel must practice within the general scope of the profession. The special interest sections are defined by the individual client served, the age of persons served, a particular area of skill or expertise, practice role, and location of practice. Table 24.3 lists the special interest sections that were in existence at the time of this writing. More than likely, no one special interest section will address all of a therapist's practice needs because practice is an integration of knowledge from many areas (AOTA, 2007a). For instance, in the case study, Kanesha chose to belong to two groups to help keep up with practice issues related to children with autism.

Each SIS provides its members with the opportunity for dialogue through its newsletters and through e-mail lists that are available to its members. These are invaluable tools for therapists who want to communicate with other therapists who have similar practice interests. Members of

TABLE 24.3   AOTA SPECIAL INTEREST SECTIONS BY FOCUS

Focus	Special Interest Section
Client health condition	Developmental Disabilities (DDSIS) Mental Health (MHSIS) Physical Disabilities (PDSIS) Sensory Integration (SISIS)
Client age	Gerontology (GSIS)
Therapy skills	Technology (TSIS) Work Programs (WPSIS)
Practice roles	Administration and Supervision (AMSIS) Education (EDSIS)

AOTA Staff

All of the efforts of this large volunteer network of members would not be possible without a highly competent and dedicated staff at the national headquarters housed in Bethesda, Maryland (Figure 24.1). The staff includes occupational therapists, attorneys, accountants, policy specialists, and administrative, clerical, and technical personnel. The national headquarters staff is led by an executive director who is responsible for all of the personnel and operations of the national headquarters. This person reports directly to the AOTA president and attends all board meetings and meetings of the RA and has voice but cannot vote. The purpose of the national headquarters is to support the efforts of the association by providing the personnel and expertise required to accomplish the association's mission and the policies and positions enacted by the RA. Some of its key operations include supporting the work of the member volunteer groups, designing and delivering continuing education, compiling evidence-based practice information, monitoring and influencing public policy, and advocating for the profession and the persons it serves and maintaining sound business operations.

Staff members who are occupational therapists serve as a liaisons to the RA, to each of the commissions, and to the special interest section steering committee. Other staff members serve as liaisons to the various committees,

the special interest sections often work collaboratively with the various commissions on projects such as defining roles and functions of occupational therapists in a particular practice arena, guiding the development of advanced competencies and specialized skills, or developing standards for education of occupational therapy personnel. Each chair belongs to the Special Interest Section Steering Committee (SISSC), which works to coordinate the efforts and collaborate on issues of mutual importance. The chair of SISSC sits on the RA with voice and vote.

Affiliation of State Association Presidents

There is an occupational therapy association in each state. These organizations are independent from AOTA but work with AOTA to advance the profession in that particular state and to advocate for the people and populations who are served by occupational therapy. The president of each state association belongs to the Affiliation of State Association Presidents. This group provides a venue for the presidents to communicate with and support each other.

Assembly of Student Delegates

Students are valued members of AOTA and belong to the Assembly of Student Delegates (ASD). Each educational program may select a student as its delegate to the ASD meeting that takes place during the AOTA Annual Conference and Exposition. ASD provides a platform for students to share their perspectives on issues that affect the profession. A representative of ASD serves in the RA and on each of the commissions.

FIGURE 24.1   AOTA's national office building in Bethesda, Maryland.

commissions, and volunteer groups in the association. The liaisons provide knowledgeable and consistent support to the committee chairs, which enables each volunteer group to address its tasks with the assurance that the necessary administrative and clerical support is available to accomplish the tasks. Staff also responds to countless requests for information from members about specific issues related to the profession.

Continuing Education and Professional Development

Another whole group of staff members develop and coordinate continuing education offerings, including live and online workshops, seminars, online courses, and self-paced clinical courses. Many of these are offered throughout the country and in varied formats designed to best meet the needs of the participants. The most evident and widely publicized event is the AOTA Annual Conference and Exposition (Figure 24.2). This major undertaking involves solicitation and selection of continuing education presentations that address the needs of the membership, recruitment of vendors for the conference marketplace, and coordination of housing and meeting rooms to accommodate the thousands of participants. AOTA members may attend at a reduced cost. This Conference and Exposition is planned and implemented by staff from the national headquarters, although volunteer members review and rank presentations that are submitted for inclusion at conference and help provide needed human resources during the actual conference.

Evidence for Practice

Another major initiative of the AOTA staff is researching the literature to locate and gather the data that provide evidence for the practice of occupational therapy. As this data are collected, they are compiled into Evidence Based Briefs that therapists and others can use to support occupational therapy intervention. In addition to the Evidence Based Briefs, AOTA maintains a Practice Directory that provides links to various publications and Internet sources containing additional information that supports practice. This directory is a valuable resource that is available to AOTA members.

Public Policy and Advocacy

An important staff role is to represent and advocate for the interests of occupational therapists and their clients in the areas of public policy. This work involves lobbying with legislators regarding initiatives that are important to the profession and to the people who are served by occupational therapy. At the federal level, this may also involve working with the policymakers from the Office of Special Education, the Rehabilitation Services Administration, and other governmental agencies regarding eligibility for service as well as guidelines for reimbursement. AOTA staff is often called on to provide information and testimony before congressional committees who make recommendations regarding the interpretation and implementation of legislation.

This group also supports the activities of state and local occupational therapy associations and licensure boards to

FIGURE 24.2 Students from Brenau University meet Dr. Penelope Moyers, president of AOTA, during the 2007 AOTA Conference and Exposition.

ensure that language supportive of occupational therapy is included in state legislation and that occupational therapy is supported and not inappropriately restricted by encroachment by other professions. AOTA staff members also provide educational materials and individual support to members and state associations to prepare them to effectively lobby, testify, and advocate for the profession and those who are served in their area by occupational therapy.

Business Operations

A number of AOTA staff members manage the business operations of the association. Income comes primarily from member dues, publications, conference registrations, and vendor fees. AOTA owns an eight-story office building in Bethesda, Maryland, that houses the national headquarters. Space in the building that is not used by the association is rented, and rental fees are a major source of the association's income. The largest category of AOTA expenses is travel and per diem support for the many members who volunteer to serve on the committees, boards, and commissions that support the work of the association. Other major expenses fund the initiatives passed by the RA and pay for staff salaries and benefits (AOTA, 2007b).

Accreditation Council for Occupational Therapy Education

Working under the umbrella of AOTA is the Accreditation Council for Occupational Therapy Education (ACOTE®). Members of the council are occupational therapists and occupational therapy assistants who are AOTA members who represent both clinical and academic interests. There is also a representative from the public. The role of ACOTE is to develop and implement the standards for all occupational therapy and occupational therapy assistant educational programs. ACOTE standards are related to all aspects of the program, including the curriculum, the credentials of faculty and staff, the content of courses, the physical facilities and resources, and the administrative policies of the school that relate to the occupational therapy program. To become accredited and to maintain accreditation, every OT and OTA program is evaluated on a regular basis by ACOTE. Completion of an occupational therapy program that is accredited by ACOTE is an eligibility requirement for students taking the certification examination (AOTA, 2007c). In the Case Study, Kanesha graduated from an ACOTE-accredited program as part of becoming an occupational therapist.

Publications

The official publication of the Association is the *American Journal of Occupational Therapy* (AJOT®). This peer-reviewed journal is available to all association members,

as it is included in their professional dues. The BOD selects the AJOT editor, who in turn selects an editorial board composed of occupational therapy scholars and practitioners, who solicit and review each submission.

The association also publishes *OT Practice,* a bimonthly magazine that includes informative articles about the profession. In addition to this magazine and the AJOT, AOTA publishes Special Interest Section Quarterlies, Newsletters on State Policy, monthly updates on legislative issues, and biweekly updates on current events that are of interest to members of the profession (AOTA, 2007d). Many of these publications are distributed electronically.

In addition to its regular ongoing publications, AOTA Press publishes books, manuals, monographs, and consumer guides that address topics of concern to occupational therapists and their consumers. AOTA also maintains a marketplace or clearinghouse for these publications, videos, and other documents as well as items that are appropriate for marketing occupational therapy. The cost of most of these items is reduced for AOTA members.

Summary

As should be obvious from this review, AOTA is an important partner for every member of the profession, providing services that range from educational standards to resources that support professional development to the advocacy needed to ensure that occupational therapists and the clients they serve are well represented in national policy decisions. Although this section has focused on AOTA, there are many parallel organizations in the countries where occupational therapy is a well accepted profession.

STATE REGULATORY BOARDS

Each state or jurisdiction regulates occupational therapy in some way. Most do this through a licensure board or regulatory agency. The definitions and guidelines are enacted by the legislature in that particular state. AOTA is a valued resource for these regulatory agencies, providing information about the profession. When students complete their Level II fieldwork and successfully pass the certification examination of the National Board for Certification of Occupational Therapists, they are eligible to apply for licenses to practice.

OTHER IMPORTANT ORGANIZATIONS

In addition to AOTA, there are other occupational therapy organizations with missions that support the profession of occupational therapy. There are two such organizations in the United States; one is a charitable foundation, and the other is the profession's credentialing body. There is also

the World Federation of Occupational Therapy, which was discussed in Chapter 23.

American Occupational Therapy Foundation

The American Occupational Therapy Foundation (AOTF) is a charitable organization that was established in 1965 to advance the science of occupational therapy and to increase public understanding of its value. The foundation comprises occupational therapists and its corporate partners that support the profession. It is financially supported by contributions and corporations that value occupational therapy. Each year, the foundation holds special events at the AOTA annual conference and exposition to raise money to support its work.

As part of its mission to advance the science of occupational therapy, AOTF publishes a scholarly journal, *Occupational Therapy Journal of Research: Occupation, Participation and Health* (OTJR). The foundation also maintains the Wilma West Library, a national clearinghouse for occupational therapy information. In addition to the excellent library, the foundation maintains OT SEARCH, a comprehensive electronic search engine for literature related to occupational therapy. OT SEARCH and the other library services are housed in the same building as AOTA headquarters in Bethesda and are available to all members of AOTA.

AOTF supports scholarship and research through scholarships and financial assistance to students whose research advances the field. Small grants are available to students for funding their research. Larger amounts are granted to scholars to fund innovative studies that may affect the profession and build understanding of occupational science. Finally, the foundation partners with higher education to fund centers of scholarship and research (AOTF, 2007).

National Board for Certification of Occupational Therapists

The profession is also supported through the work of the National Board for Certification of Occupational Therapists (NBCOT®). This board is the credentialing body for therapists and assistants practicing in the United States. Registered occupational therapists, certified occupational therapy assistants, and consumers serve on this board. NBCOT develops and administers the initial certification examinations that occupational therapists and occupational therapy assistants take following their Level II fieldwork. The examinations are comprehensive and are designed to measure the knowledge and skills required for an OT or OTA to enter practice. The items in the certification examinations are based on an extensive practice analysis of novice occupational therapists from throughout the country. The certification examination includes items that reflect occupational therapy evaluation and intervention with diverse popula-

tions in a variety of practice environments. Examination results are shared with individual state licensure boards. Achievement of a passing score on the certification examination is required in almost every state in order to be eligible to obtain a license to practice. OTs and OTAs from other countries who wish to practice in the United States must successfully complete the certification examination (NBCOT, 2007).

World Federation of Occupational Therapy

Occupational therapy is a global profession. As was discussed in the previous chapter, the World Federation of Occupational Therapy (WFOT) was created as the "official international organization for the promotion of occupational therapy." The United States is one of 57 member countries belonging to the WFOT (WFOT, 2007).

AOTA, NBCOT, and WFOT are the principal organizations in the United States concerned with occupational therapy. AOTA also actively seeks and participates in partnerships with many other groups to address areas of common concern. These organizations collaborate with AOTA to work on meeting common goals. For example, the American Society of Speech and Hearing Association (ASHA) and the American Physical Therapy Association (APTA) and AOTA have formed the TriAlliance of Health and Rehabilitation Professions, which collaborates to advocate for issues that may affect all the members of those three professions.

In addition to the TriAlliance, AOTA collaborates with other associations, nonprofit groups and coalitions to address issues of mutual concern. The primary concern of some of these groups. such as the American Arthritis Foundation, the American Foundation for the Blind, and the Alzheimer's Association, might be people who have a particular disease or condition, while other groups might collaborate with AOTA on specific issues. For example the American Association of Retired Persons (AARP), the American Automobile Association (AAA), and AOTA are working together to address the issues related to community mobility and the needs of older drivers. AOTA also collaborates with AARP and the National Association of Home Builders around home modifications and aging in place for older adults. Similarly, AOTA frequently works with coalitions of advocacy and professional groups such as the Consortium for Citizens with Disabilities (CCD) and the Mental Health Liaison Group on critical public policy issues (F. Sommers, personal communication, February 28, 2007).

CONCLUSION

It is clear that the profession of occupational therapy involves many different areas of practice and opportunity. As occupational therapists, occupational therapy assis-

tants, and occupational therapy students, we are supported by AOTA and the other organizations that provide the resources and information that we need in order to practice. As professionals, we also have the opportunity and responsibility to support and participate in our professional organizations so that we can work toward continually developing, shaping, and promoting our chosen profession.

Occupational Therapy Practitioners: Competence and Professional Development

PENELOPE MOYERS

Learning Objectives

After reading this chapter, you will be able to:

1. Understand the entry-level competencies for both occupational therapists and occupational therapy assistants.
2. Appreciate the multiple variables influencing the complexity of continuing competence and competency.
3. Differentiate among the terms continuing competence and competency, being competent, and professional development.
4. Understand and apply the Triangular Model of Continuing Competency and Competence.
5. Determine the importance of licensure and credentialing as an aspect of competence while accepting one's own responsibility for this process.
6. Be able to develop a learning plan and select the best learning activities for plan implementation.
7. Become aware of the evidence supporting continuing competency and competence.
8. Consider whether advanced and specialty certifications would be important for your practice.

*S*ociety expects practitioners to render services that reflect the standards of their profession. Changing practice settings, changes in health care technology, and new evidence all demand that practitioners must frequently develop new knowledge and skills. Practitioners are expected to take responsibility for their ongoing professional development and to carefully assess the degree to which their knowledge and skills are adequate to meet the demands of their current or anticipated practice environments. This chapter discusses aspects of that professional responsibility, primarily from the perspective of practice in the United States. The general concepts are likely to be of use internationally and include discussions of entry-level competency and the difference between competence and continuing competency. Subsequent sections of the chapter discuss the various factors associated with developing and maintaining both continuing competence and competency, ending with a discussion of advanced certification and specialty certification.

ENTRY-LEVEL COMPETENCIES

The occupational therapist and the occupational therapy assistant have different entering-level **competencies** when each begins practice. The occupational therapist receives a post-baccalaureate degree, which may either be a master's or entry-level doctorate degree; and the occupational therapy assistant receives an associate's degree. While there are differences in the depth of learning, both practitioners receive education in the liberal arts; take prerequisites in the biological, physical, social and behavioral sciences; and learn about the basic tenets of occupational therapy (Accreditation Council for Occupational Therapy Education [ACOTE®], 2007). The occupational therapist comprehends and knows how to apply the various theoretical perspectives of occupational therapy and understands the evaluation process, which emphasizes the interpretation of assessments in terms of the underlying factors contributing to problems of occupational performance as well as how the environment provides barriers to and supports for participation in daily life. The occupational therapy assistant helps with the screening and assessment process through data collection.

The occupational therapist uses the interpretation of the assessment data to formulate an intervention plan—in collaboration with the client and the occupational therapy assistant—designed to improve occupational performance and daily life participation. Both practitioners may implement the intervention plan, but the occupational therapist is ultimately responsible for the entire occupational therapy process. The occupational therapist is trained in service management within various types of service delivery models. The occupational therapy assistant supports the occupational therapist in service management and understands the influence of these service delivery

models, such as educational, medical, or community. Both practitioners read the professional literature, but the occupational therapist is able to determine how to use and apply research within practice. There is an emphasis in the education of both practitioners on advocacy, lifelong learning, professional ethics, values, and responsibilities. (See Table 25.1 for the comparison and contrast of the roles between the occupational therapist and occupational therapy assistant.)

LEARNING AND IMPROVED PRACTICE PERFORMANCE

Occupational therapy practice changes rapidly in response to up-to-date information, new knowledge, and modern technologies. Consequently, consumers and clients, employers, accreditation agencies, licensure boards, and other stakeholders expect occupational therapists and occupational therapy assistants to work actively to maintain their **continuing competency** and **competence** within specific areas of practice and within specific service delivery contexts. However, occupational therapy practitioners are challenged to assure their continuing competency and competence for many reasons:

- The skills and abilities of all practitioners fade with lack of practice, feedback, or administrative/system support
- The explosion of knowledge makes it difficult to maintain and focus learning
- Significant sophistication is required to translate these knowledge discoveries into practice, particularly given that knowledge must attend to the need for client-centered care within a confluence of cultures.
- Added to this is the pressure from complex health care and social systems that prevent change in practice (Moyers, 2005).

Additionally, there is not a linear relationship between learning and improved practice performance. Instead, there may be periods of time when there is either no improvement or even a slight decrease in performance. The dynamic interaction among the client, the practitioner, the nature of the occupation-based therapeutic intervention, and the context in which therapy is occurring influences the way in which new knowledge and skills may be applied to the practice situation. Each client situation is different; thus practitioner performance is highly context dependent. The practitioner may have better outcomes in one situation compared to another similar situation (Handfield-Jones, et al., 2002). Applying new learning to practice typically requires cognitive reorganization involving abandonment of previously held ideas and principles or incorporating this learning to restructure previously held ways of thinking. Consequently, there are periods of little change followed by sudden jumps in practice performance rather than learning demonstrated as continuous and gradual change

TABLE 25.1 DIFFERENCES IN OCCUPATIONAL THERAPISTS AND OCCUPATIONAL THERAPY ASSISTANT STANDARDS OF PRACTICE

Standards of Practice for Occupational Therapy (AOTA, 2005c)

Occupational Therapy Process	Occupational Therapist	Occupational Therapy Assistant
Screening, Evaluation, and Re-evaluation		
1. Accepts and responds to referrals in compliance with state laws or other regulatory requirements.	X	
2. In collaboration with the client, evaluates the client's ability to participate in daily life activities by considering the client's capacities, the activities, and the environments in which these activities occur.	X	
3. Initiates and directs the screening, evaluation, and re-evaluation process and analyzes and interprets the data in accordance with law, regulatory requirements, and AOTA documents.	X	Contributes
4. Follows defined protocols when standardized assessments are used.	X	X
5. Completes and documents occupational therapy evaluation results.	X	Contributes
6. Communicates screening, evaluation, and re-evaluation results within the boundaries of client confidentiality to the appropriate person, group, or organization.	X	X
7. Recommends additional consultations or refers clients to appropriate resources when the needs of the client can best be served by the expertise of other professionals or services.	X	
8. Educates current and potential referral sources about the scope of occupational therapy services and the process of initiating occupational therapy services.	X	X
Intervention		
1. Has overall responsibility for the development, documentation, and implementation of the occupational therapy intervention based on the evaluation, client goals, current best evidence, and clinical reasoning.	X	
2. Ensures that the intervention plan is documented within the time frames, formats, and standards established by the practice settings, agencies, external accreditation programs, and payers.	X	
3. Selects, implements, and makes modifications to therapeutic activities and interventions that are consistent with the occupational therapy assistant's demonstrated competency and delegated responsibilities, the intervention plan, and requirements of the practice setting.	X	X
4. Reviews the intervention plan with the client and appropriate others regarding the rationale, safety issues, and relative benefits and risks of the planned interventions.	X	X
5. Modifies the intervention plan throughout the intervention process and documents the changes in the client's needs, goals, and performance.	X	Contributes
6. Documents the occupational therapy services provided within the time frames, formats, and standards established by the practice settings, agencies, external accreditation programs, payers, and AOTA documents.	X	X

TABLE 25.1 DIFFERENCES IN OCCUPATIONAL THERAPISTS AND OCCUPATIONAL THERAPY ASSISTANT STANDARDS OF PRACTICE *Continued*		
Standards of Practice for Occupational Therapy (AOTA, 2005c)		
Occupational Therapy Process	*Occupational Therapist*	*Occupational Therapy Assistant*
Outcomes		
1. Responsible for selecting, measuring, documenting, and interpreting expected or achieved outcomes that are related to the client's ability to engage in occupations.	X	
2. Responsible for documenting changes in the client's performance and capacities and for discontinuing services when the client has achieved identified goals, reached maximum benefit, or does not desire to continue services.	X	Contributes
3. Prepares and implements a discontinuation plan or transition plan based on the client's needs, goals, performance, and appropriate follow-up resources.	X	Contributes
4. Facilitates that transition process in collaboration with the client, family members, significant others, team, and community resources and individuals, when appropriate.	X	X
5. Responsible for evaluating the safety and effectiveness of the occupational therapy processes and interventions within the practice setting.	X	Contributes

(Handfield-Jones, et al., 2002). There seem to be periods where practice performance improves in some areas, while simultaneously deteriorating in others.

To facilitate understanding of the complex issues of remaining updated, this chapter examines the Triangular Model of Competency and Continuing Competence (Figure 25.1). The goal is to become familiar with AOTA *Standards for Continuing Competence* (2005) and the way in which they serve as indicators of achieving the competencies associated with one's professional responsibilities. The *AOTA Professional Development Tool* (PDT) (AOTA, May, 2003) is described as a guideline for constructing a reflective portfolio useful in documenting one's efforts toward continuing competence. The National Board for Certification in Occupational Therapy (NBCOT) processes for initial certification and certification renewal are briefly explained along with AOTA's board and specialty certification programs, which use self-assessment and self-appraisal approaches. The importance of state licensure is highlighted.

WHAT DOES IT MEAN TO BE COMPETENT?

There is an important difference between the terms *continuing competence* and *continuing competency;* however, the word *continuing,* in front of each term, indicates the significant focus on lifelong learning. **Continuing com-**

petence "refers to an individual's capacity to perform job [professional] responsibilities" (McConnell, 2001, p. 14). For instance, Maria, who is an occupational therapist, is working with persons with schizophrenia within an inpatient setting, and she plans to develop a club house model program for her clients who return to the community. She needs to focus her learning on the theoretical aspects of the club house model, evidence of the approach's effectiveness, and the business models for its implementation. This building capacity involving the preparation for significant change in practice is continuing competence.

"**Continuing competency** focuses on an individual's actual performance in a particular situation" (McConnell, 2001, p. 14). *Competency* implies a determination of whether one is competent to perform a behavior or task as measured against a specific criterion (Hinojosa, et al., 2000a). Tiffany, an occupational therapy assistant, has just taken a position at the local hospital. Before she can begin seeing clients with occupational performance problems related to the upper extremity, she must demonstrate her skills or competency to the supervising occupational therapist in using standardized hand therapy assessments, splinting, and implementing interventions according to evidence-based and occupation-based protocols developed for each type of diagnosis or surgical intervention.

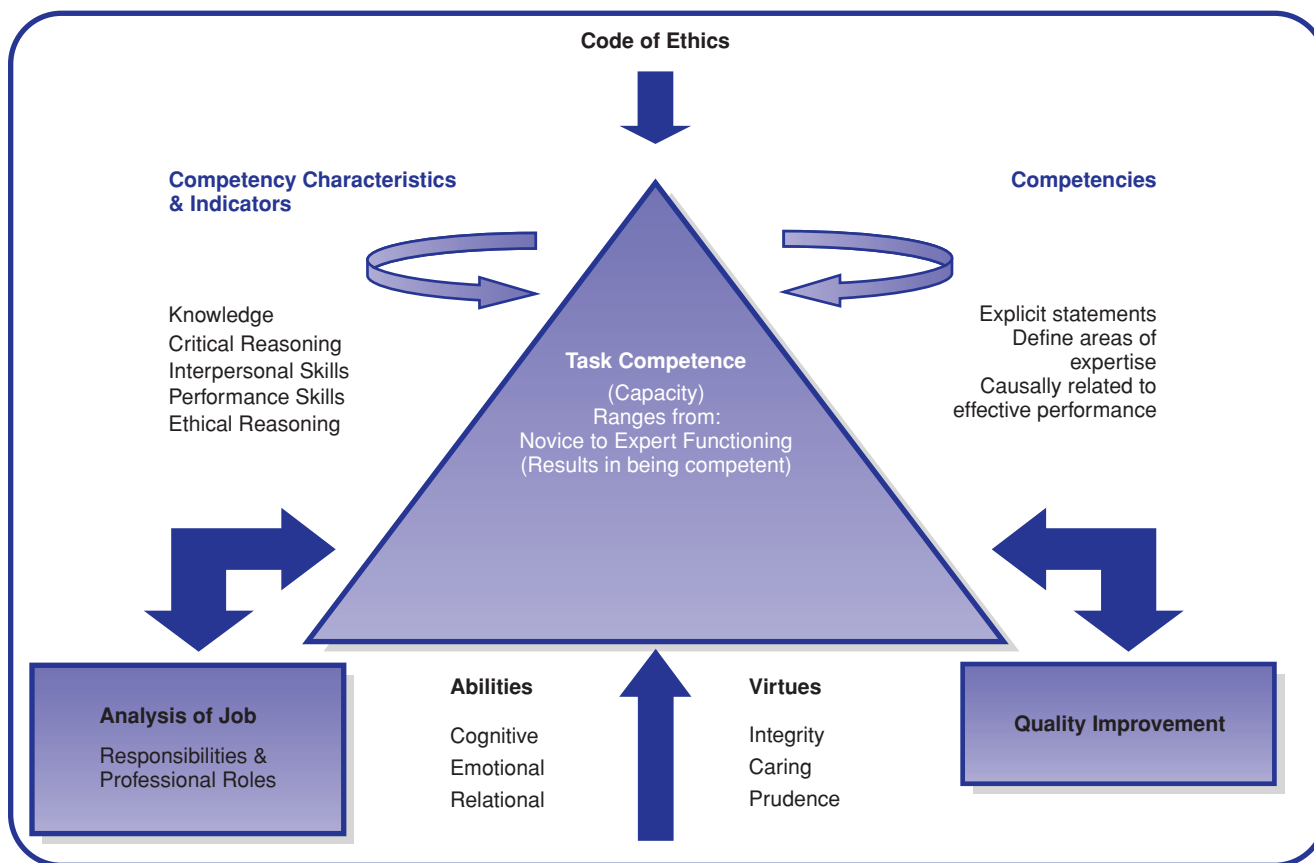
Being **competent** involves the ability to select the best assessment tools, intervention approaches, and outcome measures according to the evidence indicating effectiveness and efficacy as well as to skillfully provide the appro-


FIGURE 25.1   Triangular Model of Continuing Competency & Competence.

priate services to meet the needs of the client (Moyers, 1999). Competent occupational therapy practitioners have the prerequisite knowledge, skills, and attitudes that authorize them to perform restricted, skilled activities resulting in defined client outcomes. Only someone licensed or regulated in a given profession or technical trade may perform a restricted activity, or those processes and procedures ascribed to particular professions or job classifications where specific education and training is required (Moyers & Hinojosa, 2003).

The next important distinction in terms is contrasting *professional development* with *continuing competence* and *continuing competency*. **Professional development** is a career development process and focuses on what the occupational therapy practitioner wants to learn in order to achieve future career aspirations, such as becoming an expert clinician, administrator, educator, researcher, consultant, or private practitioner. The focus of professional development is on determining the future roles you would like to develop and the kinds of tasks and knowledge that are included in these roles. With an understanding of the possible tasks within these future roles, you can begin to determine the skills and reasoning needing further development as well as the criteria used for measuring successful performance.

FACTORS AFFECTING CONTINUING COMPETENCY AND COMPETENCE

Ultimately, the interest in competence is because there are risks associated with poor intervention. When interventions are provided incompetently, they may harm the client, the results of which may in turn raise a further risk of a legal liability for malpractice. Providers, payers, business and industry, social service agencies, and service recipients expect effective intervention leading to desired outcomes. Although there are many factors contributing to unsatisfactory outcomes, practitioners who have not consistently updated their knowledge and skills could be a source of practice errors. The triangular model of continuing competency and competence explains the elements contributing to one's success in remaining proficient (Moyers, 2005). (see Figure 25.1)

The Case Study about José helps in understanding why job task competence is situated at the center of the Triangular Model for Continuing Competency and Competence (Figure 25.1). Occupational therapy practitioners may perform a variety of duties including those of a practitioner, fieldwork supervisor, manager or administrator, consultant, entrepreneur, advocate, educator, researcher,

CASE STUDY: *José: A Therapist Improving Competence and Competencies*

José is an occupational therapist with three years of experience working with clients with brain injury providing both inpatient rehabilitation and outpatient community re-entry programs. His past performance evaluations from his supervisor indicate José enjoys learning, relates well with others, and exudes a calming and rational influence on staff and clients alike. These are all important abilities underlying continuing competence and competency. He displays the necessary virtues in that he genuinely cares for his clients, has the integrity to focus learning on areas of weakness, and the prudence to select learning methods that will help him apply learning to practice. According to the analysis of his responsibilities, the competencies primarily related to his job involve evidence-based evaluation, intervention planning and implementation, discharge planning, community re-entry program implementation, and outcome measurement, all with a focus on occupational performance in daily life participation.

Although no longer being a novice in performing these competencies, his client outcomes indicate that there is a group of clients with high no-show rates in the community re-entry program. When surveying this group of clients, they indicate feelings of depression and unresolved problems with vision. The caregivers of these clients describe their behavior as being difficult to manage because the clients are often argumentative and angry, and often refuse to perform many daily living tasks in which they had previously engaged prior to their head injuries. José schedules a meeting with his supervisor to develop some learning goals related to training caregivers in behavior management, and evaluation and intervention for depression and visual problems. His supervisor agrees that this learning plan will improve his competency, but also wants to bring to the attention of José that the hospital will be putting in place a new documentation and outcome measurement system, with a phase-in process over the next two years. José agrees to add this continuing competence issue into his learning plan.

In order to more fully develop his learning plan, José realizes that he needs to decide how to break-down his learning goals so that he will select the best learning methods that will help him apply the learning to his practice so that

his client no-show rate in the community re-entry program will decline. He decides that he knows a lot about behavior management (competency characteristic), but needs to learn the best way to teach this knowledge (performance skill) to the caregivers so that they will be able to implement these strategies to better support their clients' daily performance. He is worried about how to give feedback in a way that is constructive and does not ruin rapport (interpersonal skill) when working with the caregivers in their practice of these new behavior management skills. Thus, he has identified some potential mismatches between his current competency and knowledge and those needed in the future. He also realizes that he received only basic information (competency characteristic) in his entry-level program about the vision issues of persons with head injuries and that he needs to begin improving his knowledge and critical reasoning through some continuing education courses, reading the research literature, and studying some case studies. As his knowledge and critical reasoning improves, he decides to contact a local occupational therapist with expertise in the vision issues of persons with head injuries to mentor him in his critical and ethical reasoning, and to perhaps provide some observational opportunities and supervised practice experiences (performance skills).

His supervisor provided some of the resources for learning in terms of paying for one continuing education course in low vision and providing the training in the new documentation and outcome measurement systems; however, José knew it was his ethical responsibility to search out and implement other learning opportunities beyond what his employer was willing to provide. His employer, however, was prepared to purchase the recommended supplies or equipment to support application of his learning to practice as she knew José had carefully researched which equipment would most likely be economical as well as effective in evaluating and providing intervention for persons with vision problems affecting their occupational performance. José worked out with his supervisor a plan for program changes in the community re-entry program as well as how to incorporate the new documentation and measurement system.

scientist, or scholar. Regardless of the variety of professional roles held, the occupational therapist and occupational therapy assistant must successfully manage the multiple responsibilities inherent in the job. Job task competence ranges from being a novice to being an expert not only depending upon experience with the task, but depending on the various contextual factors dynamically interacting with the job task. New work tasks or projects or working within new contexts, even though the occupational therapy practitioner might have a lengthy tenure in

a particular job, result in the employee being considered a novice. Even though normally being an expert in a particular job task, a client from a culture different from any clients one has previously provided intervention, may create a task situation in which the expert is performing more at the novice end of the continuum because of the cultural complexities added to the situation.

According to Principle 4 of the *Occupational Therapy Code of Ethics* (AOTA, 2005b), it is the duty of the occupational therapy practitioner to achieve and continually

maintain high standards of competence. Therefore, when encountering work tasks, projects, or contexts in which one is a novice, the occupational therapy practitioner must engage in a self-initiated approach to develop and implement an individualized plan for learning (Hinojosa, et al., 2000b). A learning plan is based on an analysis of the job and quality improvement data to determine the explicit statements or competencies that are causally related to effective job performance or client outcomes.

Competencies typically address those that are generic across all jobs in an organization (e.g., a customer service orientation), those that are related to management or supervision roles (e.g., budgeting or personnel management), those that are threshold or that are the minimum requirements of a job (e.g., being able to evaluate a client), and those that are specific to a job (e.g., being able to conduct a feeding and swallowing evaluation) (Decker & Strader, 1997).

Once competencies and outcomes are determined, the next step is to delineate the indicators fundamental to these competencies (Decker & Strader, 1997). The triangular model of competency and continuing competence uses the *Standards for Continuing Competence* (AOTA, 2005a) as indicators. These include knowledge, critical and ethical reasoning, and performance and interpersonal skills. For example, the competency of client evaluation requires selecting the most appropriate assessment instruments given the client's condition, selecting goals and preferences for specific outcomes, and requiring the adept administration of the tools to yield accurate and reliable data. This competency requires knowledge of a variety of assessment instruments, the critical and ethical reasoning skills to determine which would be the best test given the nature of the instrument and the client circumstances, and the interpersonal and performance skills to conduct the assessment properly while developing empathy with the client. Competency characteristics are intrinsic to the occupational practitioner and include such aspects as expert knowledge and skills, motivation to change performance, positive self-concept that one can become proficient, and attitudes conducive for and a value of learning. If there is a mismatch between the competency statement and the competency characteristics, such as being unaware of available assessment instruments, the occupational therapist in this instance must devise a plan to improve the knowledge needed for achievement of the competency.

Remaining competent and pursuing competence depends upon the occupational therapy practitioner's cognitive, emotional and relational abilities. In order to learn, the occupational therapy practitioner must use the requisite cognitive and intellectual abilities to understand and synthesize complex information. The occupational therapy practitioner must demonstrate a well-adjusted personality, which involves the emotional abilities of open-mindedness, flexibility, and self-monitoring or self-regulation. In addition, the occupational therapy practitioner must have the relational abilities to successfully establish rapport with and advocate for clients and their families or relevant others.

There are also specific virtues related to competence where the occupational therapy practitioner is called upon to aspire toward ideals and to develop virtues of character enabling achievement of those ideals. Integrity involves honesty and sincerity, caring involves the understanding of the altruistic responsibility associated with client service provision, and prudence involves the ability to govern and discipline oneself through the use of reason (AOTA, 1993). These virtues help motivate the occupational therapy practitioner to learn because of the desire to perform better on behalf of the client (caring). Prudence facilitates the disciplined implementation of the learning plan developed in an honest way in terms of making a sincere attempt to achieve job competence as opposed to implementing a plan that focuses on what is easiest or most convenient to learn.

WHO DETERMINES WHETHER SOMEONE IS COMPETENT?

Credentialing, such as state licensure, is an indicator to the public that the health care practitioner has some level of competence to provide skilled services within a specified scope of practice; however, the public is increasingly aware that licensure reflects the minimal standards of competence necessary to protect the public (Grossman, 1997). State licensure boards are primarily responsible for entry into practice by requiring occupational therapy practitioners to pass the examination administered by the National Board for Certification in Occupational Therapy (NBCOT) after completing an accredited educational program in occupational therapy and the required fieldwork. Background checks and fingerprinting may be required as well.

Renewal of the license to practice in a jurisdiction occurs when the practitioner pays a fee. Renewal of the license may also be dependent upon evidence of continuing education, adherence to ethical standards, and evidence of knowledge about the laws and regulations governing occupational therapy practice (jurisprudence tests). The occupational therapy practitioner also has to attest prior to renewal that he or she has never been sued or had an award for malpractice or negligence made against him or her, and never had the license or practice privileges revoked or suspended. If answers to these questions are positive, the licensure board launches an investigation to determine whether the license to practice should be renewed.

While state licensure focuses upon restricting entry to practice in a given jurisdiction to those who are appropriately qualified and who regularly maintain their license, NBCOT, a private credentialing body, awards the ability of occupational therapists to use the initials OTR® and the occupational therapy assistant to use the initials COTA®. Ability to use the credentials depends upon the initial successful completion of the entry examination and then

upon regularly renewing the certification. This certification renewal program is voluntary, is not required by most state regulatory boards, and is not required to receive Medicare or Medicaid reimbursement for the delivery of occupational therapy services. Some employers may require renewal with NBCOT. Renewal of the NBCOT certification involves the collection and documentation of professional development units (PDUs), (some of which must have direct bearing on occupational therapy), through engagement in a variety of learning activities (NBCOT, 2006).

Licensure boards and certification granting organizations tend to use the most common approach in determining competence, which is through testing, credentialing and requiring the appropriate continuing education. However, quality of care is an example of a construct that cannot be directly observed nor measured in all aspects. Certification tests used by many certification programs cannot evaluate how well the applicant actually performs in a given practice situation.

Therefore, understanding the emerging concept of context specificity creates debate regarding the way competence is currently defined and measured. Context specificity indicates that "an individual's performance on a particular problem or in a particular situation is only weakly predictive of the same individual's performance on a different problem or in a different situation" (Eva, 2003, p. 587). According to this definition, competence is best determined by observing the occupational therapy practitioner complete the key competencies important to successful job performance and client outcomes. Due to the expense and impracticality of performance-based testing, the methodology and resources are not feasible at this time for use by licensure boards and other credentialing bodies. Instead, employers may be in the best position to actually determine competency, which has been a recent focus of such organizational accreditation programs as the Joint Commission on the Accreditation of Healthcare Organizations (JCAHO). According to these standards, health care organizations have to prove, track, and improve the competence of employees (Herringer, 2002). The renewal programs of licensure boards and other credentialing bodies are really focusing on pursuit of continuing competence and capacity to perform in the certification area.

WHO IS RESPONSIBLE FOR ENSURING WHETHER SOMEONE IS COMPETENT?

Regardless of legal requirements associated with licensure for maintaining competence and the importance of competence to employers, it is the professional duty of the practitioner, according to the AOTA Code of Ethics (2005b), to assess, maintain, and document his or her own competence. Given that competence is the primary responsibility of the professional, Hinojosa et al. (2000b) outlined AOTA's Continuing Competence Plan for Professional Development as involving nine components, each of which is described in Box 25.1.

Development and implementation of the continuing competence plan can be guided through the use of AOTA's Professional Development Tool (AOTA, May, 2003) which is a framework for building a portfolio that can be used with licensure boards, employers, NBCOT, and AOTA advanced and specialty certifications.

As AOTA's plan for continuing competence suggests, the professional should judge his or her competence according to the current job responsibilities. Does the practitioner have the required knowledge, critical and ethical reasoning ability, and interpersonal and performance skills necessary to perform successfully and to facilitate client achievement of specified outcomes? There is need to maintain skills required for implementing the core of occupational therapy, to develop a specialized knowledge

---

BOX 25.1 | **COMPONENTS OF CONTINUING COMPETENCE PLAN**

1. Recognition of triggers that signal the need to examine competence
2. Examination of one's practice responsibilities
3. Self-assessment of one's competence status for a given responsibility
4. Identification of competence-related educational needs in light of the *Standards for Continuing Competence* (AOTA, 2005a)
5. Development of a competence improvement plan
6. Implementation of the competence plan
7. Documentation of professional development and change in competence
8. Implementation of changes in practice based on new competence, and
9. Demonstration of continuing competence

Adapted from Hinojosa et al (2000b, p. CE-1). Used courtesy of AOTA.

and skill base, and to obtain advanced abilities. For instance, although the core of occupational therapy does not change, the technology related to promoting a client's adaptation or to analyzing an occupation and its associated activities may change.

HOW DO YOU KNOW HOW TO SELECT THE MOST EFFECTIVE LEARNING ACTIVITIES?

In order to develop an effective learning plan, you need to be aware of the best methods for learning performance and interpersonal skills, gaining knowledge, and developing critical and ethical reasoning related to your job competencies. For example, reading may lead to increased knowledge, but role-playing and simulation strategies may be more effective in enhancing interpersonal abilities. The critical issue in selecting learning methods is to use cognitive processes similar to the creative thinking typical of the intricacy of today's practice environment (Fraser, & Greenhalgh, 2001). Therefore, learning approaches should help the practitioner "appraise the situation as a whole, prioritize issues, and then integrate and make sense of many different sources of data to arrive at a solution" (p. 801). These creative learning approaches often involve story telling, case histories, reflection, and problem-based learning strategies. There is an emphasis on self-directed learning where content in the subject matter varies depending on the needs of the learner and there is a use of a variety of learning approaches including experiential learning, networking, list serves for professional interest groups, opportunities to teach others, and time for feedback on the application of the learning (Fraser & Greenhalgh, 2001, p. 802).

COMMENTARY ON THE EVIDENCE

Do Continuing Education and Audits Improve Professional Practice?

O'Brien, et al. (2001) completed a systematic evidence review of randomized trials and quasi-experimental studies to examine the effect of continuing education meetings (including lectures, workshops, and courses) on the clinical practice of health professionals or health care outcomes. Included were thirty-two studies involving from 13 to 411 health professionals (total N = 2995). Within these studies, there was substantial variation in the targeted behaviors, methods for measuring baseline performance, the characteristics of the learning interventions, and the results. The types of planned educational activities studied included meetings, conferences, lectures, workshops, seminars, symposia, and courses that occurred off-site from the practice setting. These educational activities were classified into the general learning methods of interactive workshops, combined workshops and didactic presentations, and those with only didactic presentations. The authors concluded from their analysis that interactive workshops resulted in moderately large changes in professional practice, while didactic sessions alone were unlikely to change professional practice.

Jamtvedt, Young, Kristoffersen, O'Brien, and Oxman (2006) conducted another systematic review of randomized trials to assess the effects of audit and feedback on the practice of health care professionals and patient outcomes. Audit and feedback was defined as any summary of clinical performance over a specified period of time that reported objectively measured professional practice outcomes. They investigated the variation in the effectiveness of interventions across: the type of intervention (audit and feedback alone, audit and feedback with educational meetings, or multifaceted interventions that included audit and feedback), the intensity of the audit and feedback, the complexity of the targeted behavior, the seriousness of the outcome, baseline compliance and study quality. Based upon the 118 studies reviewed, the authors concluded that providing health care professionals with data about their performance (audit and feedback) may help improve their practice; however, the effects were variable and, when effective, produced a small to moderate impact on client outcomes.

These two systematic reviews are important in that it is clear that the learning methods chosen may have differential ability to positively impact client outcomes. Learners must therefore be clear whether they are trying to gain knowledge, improvements in critical and ethical reasoning, or enhanced performance and interpersonal skills. Didactic or lecture style presentations may augment knowledge, but may not lead to application of this knowledge to practice in comparison to more active learning methods and use of feedback on performance.

WHAT DOES ADVANCED AND SPECIALTY CERTIFICATION MEAN?

Specialization refers to becoming proficient in a particular practice area, diagnostic category, or intervention approach. However, specialization is often confused with advanced practice. The public typically views the advanced practitioner as an independent practitioner who possesses a high degree of skill because of more complicated responsibilities. Madill and Hollis (2003) described the key competency characteristics of the advanced health care practitioner as possessing a breadth and depth of knowledge with concerted efforts to continuously add new knowledge, an appreciation of the wider environmental context, the ability to use critical thinking and analysis, extensive contribution to one or more areas of practice, commitment to quality, motivation to continually develop new skills, and advanced qualifications (p. 32). One may be at the entry-level of a specialized area or may be at the advanced level of a specialized area. Whether specialized or advanced, competence includes the practitioner's abilities to implement the core of occupational therapy practice, as well as abilities to work within specialized practice areas, ranging from the entry to the advanced levels, depending on the requirements of the job (Youngstrom, 1998, p. 719).

The AOTA board (mental health, pediatrics, gerontology, and physical rehabilitation) and specialty certifications (low vision; feeding, eating, and swallowing; environmental modification; and driving and community mobility) are examples of ways to stimulate an occupational therapy practitioner's continuing competence, which involves the development of capacity and competency characteristics needed for the future. There are specialty certifications offered through other organizations, such as the Certified Hand Therapist credential from the Hand Therapy Certification Commission (www.htcc.org). See Table 25.2 for examples of advanced and specialty certifications.

TABLE 25.2   ENTRY LEVEL AND POST-ENTRY LEVEL CERTIFICATIONS IN THE UNITED STATES

Credentials		Granting Organization
Entry-Level Credentialing & Certification Renewal		
ACOTE Accredited	Refers to the status of an occupational therapy education program that is fully accredited	ACOTE
OTR	Occupational therapist, registered (professional level)	NBCOT
COTA	Certified occupational therapy assistant (technical level)	NBCOT
Advanced Practice Certifications		
BCG	Board Certification in Gerontology	AOTA-BASC
BCMH	Board Certification in Mental Health	AOTA-BASC
BCP	Board Certification in Pediatrics	AOTA-BASC
BCPR	Board Certification in Physical Rehabilitation	AOTA-BASC
Specialty Certifications		
ATP	Assistive Technology Practitioner	RESNA
CCM	Certified Case Managers	CCMC
CDRS	Certified Driving Rehabilitation Practitioner	ADED
CHT	Certified Hand Therapist	HTCC
CLVT	Certification in Low Vision Therapy	ACVREP
CPE	Certified Professional Ergonomist	BCPE
CVE	Certified Vocational Evaluation Specialist	CCWAVES
SCDCM	Specialty Certification in Driving & Community Mobility	AOTA-BASC
SCEM	Specialty Certification in Environmental Modification	AOTA-BASC
SCFES	Specialty Certification in Feeding, Eating, & Swallowing	AOTA-BASC
SCLV	Specialty Certification in Low Vision	AOTA-BASC

ACOTE, Accreditation Council for Occupational Therapy Education; AOTA-BASCP, American Occupational Therapy Association: Board and Specialty Certification programs; ACVREP, Academy for Certification of Vision Rehabilitation and Education Professionals; ADED, Association for Driving Rehabilitation Specialists; BCPE, Board of Certification in Professional Ergonomics; CCMC, Commission for Case Management Certification; CCWAVES, Commission on Certification of Work Adjustment and Vocational Evaluation Specialists; HTCC, Hand Therapy Certification Commission; RESNA, Rehabilitation Engineering & Assistive Technology Society of North America

These AOTA certifications require the applicant to develop a reflective **portfolio**. These are growing in popularity as "[professional development] tools that aggregate assessment information across time" (Melnick, 2004, p. s44). A reflective portfolio archives for each competency carefully appraised learning activities, the appropriate evidence of this learning, reflections on this learning, and for board only, a **self-assessment** or identification of needs for and a plan for new learning. **Self-appraisal** of learning activities answers the question: What evidence would best indicate I have acquired the competencies needed for specialized or advanced practice? In other words, the portfolio is not a collection or scrapbook of everything one has done, but requires careful selection of learning activities thought most likely to contribute to one's capacity for achieving the competency in a given context.

Self-appraisal thus begins with examining the competency statement and the client outcomes in order to make decisions about how best to learn. A wide variety of learning activities may be used to achieve each competency. Multiple methods of learning are encouraged and rewarded as the learner determines how best to enable the following results (Miller, 1990):

- *Knowing and knowing why:* Learning methods that increase the knowledge needed to have a significant impact on improved client outcomes.
- *Knowing how, when, and with whom:* Learning methods that are focused on the learner developing and using critical and ethical reasoning, in other words, knowing not only the steps, but when and with whom to use the procedures.
- *Showing how:* Learning methods that facilitate skill development so that one can actually perform the steps and procedures in various contexts.
- *Doing:* Learning methods that facilitate application of knowledge, critical and ethical reasoning and interpersonal and performance skills to practice in a consistent manner. This application results in a change in client outcomes.

CONCLUSION

Continuing competence and competency and professional development are the responsibility of the practitioner, educator, administrator, and researcher. The public, our clients, our colleagues, and our employers expect that competent occupational therapists and occupational therapy assistants are providing high quality services. Learning must be managed systematically through careful self-assessment of one's client outcomes, job responsibilities, and future trends in service delivery. Self-assessment helps the practitioner devise a learning plan complete with learning activities most likely to lead to a change in practice. The plan must be properly implemented with the help from administration to apply and evaluate the consequence of the new learning in practice.

PROVOCATIVE QUESTIONS

1. How does one avoid engaging only in learning activities one finds interesting rather than what one needs to know to practice more effectively?
2. What are some ways to ensure new learning is applied to practice?
3. How will you know if your new learning application to practice is effective?

Fieldwork: The Transition from Student to Professional

26

MARY E. EVENSON

Learning Objectives

After reading this chapter, you will be able to:

1. Comprehend how fieldwork is integral to the educational curriculum and one's own professional development.
2. Realize the requirements and levels of fieldwork education in U.S. and international academic occupational therapy programs.
3. Become familiar with traditional and innovative types of fieldwork settings and supervision models.
4. Grasp the dynamic nature of the personal and professional transitions that are inherent in the role shifts from that of being a student to assuming the role of a professional.
5. Appreciate the roles and responsibilities of those stakeholders who are involved in the fieldwork education process.
6. Gain an understanding of the process and types of competencies that are used to evaluate student fieldwork performance.

Fieldwork can be defined as "Work done or firsthand observations made in the field as opposed to that done or observed in a controlled environment" (Pickett, 2000). For occupational therapy education, fieldwork is most often referred to as work done outside of the classroom. The consensus within the occupational therapy profession is that the fieldwork experience plays an integral role in professional development. In 1923, the first standards requiring fieldwork experiences were approved by the American Occupational Therapy Association (AOTA) (Pressler, 1983). Fieldwork continues to function as the critical link between the academic world of theory and the world of practice, demonstrating the value the profession places on experience-based curricula (Cohn & Crist, 1995; Lewis, 2005).

Fieldwork experiences are intended to provide students with opportunities to carry out professional responsibilities under supervision of professionals who also act as role models (Accreditation Council for Occupational

Therapy Education, 2007). Working in the context of real-life practice, students develop a multitude of skills that enable them to establish the foundations of their future practice career. The two main categories of skill development that are inherent in participating in fieldwork are (1) the core skills and techniques that are relevant to occupational therapy service delivery for a given setting and (2) the personal skills that evolve and transform one's level of professional behavior (Missiuna, Polatajko & Ernest-Conibear, 1992). Fieldwork provides a venue for enculturation into the field as the interplay between the student as a person, the profession, and the environment support the development of a professional identity along with a set of basic professional competencies (Alsop & Donald, 1996). This component of education functions as the gateway into the profession because it enables students to establish the fundamental skills of the profession that will support them in transitioning from the practice context of fieldwork into employment. Furthermore, students in Canada and the United States, for example, must complete fieldwork requirements to become eligible to take the respective national certification examinations.

The process and content of fieldwork experiences have been debated over the years. Yet the value of having an opportunity to integrate academic knowledge with application skills at progressively higher levels of performance and responsibility has always been acknowledged (AOTA, 2003; Pressler, 1983). Christie, Joyce, and Moeller (1985) highlighted that value by documenting the fieldwork experience as having the greatest influence on the development of a therapist's preference for a specific area of clinical practice. Of the 131 therapists who were surveyed, 55% indicated that clinical practice preferences were either formed or changed during the fieldwork experience, and another 24% noted that fieldwork experience expanded their interests to other areas of practice. Similarly, Crowe and Mackenzie (2002) examined the influence of fieldwork on preferred future practice areas of occupational therapy students. This study also demonstrated that "students use the fieldwork experience to guide their decision to enter an area of practice" (Crowe & Mackenzie, 2002, p. 25). Thus, the fieldwork experience can be rich and rewarding, and as such, it is likely to have a tremendous bearing on a student's career choices.

PURPOSE AND LEVELS OF FIELDWORK: UNITED STATES

The purpose of fieldwork education is to provide students with opportunities to apply the knowledge, skills, and attitudes that they learn in the classroom into their practice in the fieldwork setting (Costa, 2004). The Accreditation Council for Occupational Therapy Education (ACOTE) Standards and Interpretative Guidelines (ACOTE, 2007)

outline the general fieldwork requirements for students. The requirements are divided into two classifications: Level I and Level II fieldwork. Level I fieldwork offers students practical experiences that are integrated throughout the academic program. The ACOTE standards describe **Level I fieldwork** as "experiences designed to enrich didactic course work through directed observation and participation in selected aspects of the occupational therapy process" (ACOTE, 2007). For both occupational therapy and occupational therapy assistant students, the goal of Level I fieldwork is to introduce students to the experience, "to apply knowledge to practice, and to develop understanding of the needs of clients" (ACOTE, 2007).

Level I Fieldwork Experience

Through Level I fieldwork experiences, students are exposed to the values and traditions of occupational therapy practice and have the opportunity to examine their reactions to clients, systems of service delivery, related personnel, and potential role(s) within the profession. Because the academic Level I performance expectations and specific purposes of the Level I fieldwork experience vary in each occupational therapy curriculum, the timing, length, requirements, and specific focus of the experience are determined by each academic program on an individual basis (AOTA, 1999a). For example, schedule options may include full or half days throughout an academic term, a one-week placement, or otherwise prearranged visits to fieldwork sites.

A study of contexts and perceptions of Level I fieldwork in current practice revealed that the number of placements in emerging practice is growing and that students generally rated their Level I fieldwork experiences as positive (Johnson, Koenig, Piersol, Santalucia, & Wachter-Schutz, 2006). In examining the types of learning opportunities that are afforded to Level I students, observation and communication skills were the most commonly practiced skills across all types of settings (Johnson et al., 2006). Practice of additional clinical skills during Level I fieldwork most frequently included fine and gross motor activities (94%) in pediatrics, range of motion (82%) in physical disabilities, interviewing (77%) in emerging practice settings, and behavioral management (73%) in mental health settings (Johnson et al., 1006, p. 281). Overall, students felt that their learning experience was maximized when they had an opportunity to practice skills and to experience occupation-based practice.

One model of fieldwork that can support students in practicing skills on Level I fieldwork and carrying them over into their Level II placements is the **Same Site Model of Fieldwork** (Evenson, Barnes, & Cohn, 2002). This unique approach provides continuity in structuring learning whereby a student completes a Level I and Level II fieldwork experience at the same training site. Exploratory investigation has shown that students and fieldwork edu-

cators identified the perceived benefits of this model to include becoming familiar with the setting, increasing comfort by lessening anxiety, and gaining preparation for Level II fieldwork.

Level II Fieldwork Experience

The goal of **Level II fieldwork** for the occupational therapy and occupational therapy assistant student is "to develop competent, entry-level generalist" practitioners (ACOTE, 2007). ACOTE (2007) Accreditation Standards state that "Level II fieldwork must be integral to the program's curriculum design and must include an in-depth experience in delivering occupational therapy services to clients, focusing on the application of purposeful and meaningful occupation." The goal of students participating in administration and management of occupational therapy services and research is differentiated for occupational therapy Level II fieldwork when applicable. Additional learning outcomes for occupational therapy Level II fieldwork are to "promote clinical reasoning and reflective practice; to transmit the values, beliefs, that enable ethical practice; and to develop professionalism and competence as career responsibilities" (ACOTE, 2007). For occupational therapy assistant students, the purpose of Level II fieldwork is to "promote clinical reasoning, appropriate to the occupational therapy assistant role" as well as to achieve professionalism and competence (ACOTE, 2007).

Initially working under direct supervision, students test firsthand the theories and facts that they learned in academic study and have a chance to refine skills through interaction with clients across the life course, with clients' families, and with team members while working in various service delivery settings and systems. As the students' abilities grow, supervision may become less direct as appropriate for the setting and the severity of the client's condition. A **developmental model of supervision** can be applied as an approach for planning, intervening, and evaluating the students' readiness for learning and participation throughout the trajectory of a fieldwork placement. Within a developmental framework, the learner and supervisor relationship progresses through four different phases: directive, coaching, supportive, and delegation (Barnes & Evenson, 2000). In all, supervision of students must meet existing local, state/provincial, and/or federal/national safety and health requirements for relevant policies, laws, and regulations for occupational therapy practice.

For students, the overall purpose of the fieldwork experience is to gain mastery of occupational therapy clinical reasoning and techniques to develop entry-level competence. Effective oral and written communication of ideas and objectives that are relevant to the roles and duties of an occupational therapist or occupational therapy assistant, including professional interaction with clients and staff, is expected of all students. Students are responsible for demonstrating a sensitivity to and respect for client con-

fidentiality, establishing and sustaining therapeutic relationships, and working collaboratively with others. Another expectation-more internal to the students' development of positive professional self-images-includes taking responsibility for maintaining, assessing, and improving self-competence. Students are responsible for articulating their understanding of theoretical information and identifying their abilities to implement evaluation or intervention techniques. Moreover, the ability to benefit from supervision as a resource for self-directed learning is *crucial* to professional development.

The requirements established by ACOTE (2007) include a minimum of the equivalent of 24 weeks full-time of Level II fieldwork for occupational therapy students in a minimum of one setting if it is reflective of more than one practice area, or in a maximum of four different settings and a minimum of the equivalent of 16 weeks full-time for occupational therapy assistant students in a minimum of one setting if it is reflective of more than one practice area or in a maximum of three settings. Level II fieldwork may be completed on a part-time basis "as defined by the fieldwork placement in accordance with usual and customary personnel policies as long as it is at least 50% of a full-time equivalent at that site" (ACOTE, 2007). Alternatives to full-time fieldwork, such as part-time models or 12-month experiences, are becoming more common (Adelstein, Cohn, Baker, & Barnes, 1990; Phillips & Legaspi, 1995).

FIELDWORK: INTERNATIONAL PERSPECTIVES

Internationally, the World Federation of Occupational Therapy (WFOT) Minimum Standards for the Education of Occupational Therapists (Hocking & Ness, 2002) require that students complete a minimum of 1,000 hours of approved clinical fieldwork that is spread throughout all years of an academic program. The WFOT requires that fieldwork placements be in locations that offer different levels of health care, such as acute care, rehabilitation, disability, community, and wellness settings. Within these types of settings, fieldwork must provide students with the opportunity to work with people of different ages who have acute and chronic health needs, delivering interventions that focus on the person, the occupation, and the environment (Hocking & Ness, 2002). At least some fieldwork placements must be of up to eight weeks' duration to enable a comprehensive learning experience. Targeted learning outcomes for graduates of WFOT-approved educational programs are to demonstrate knowledge, skills, and attitudes in the following competencies: the person-occupation-environment and its relationship to health, therapeutic and professional relationships, occupational therapy processes, professional reasoning and behavior, and the context of professional practice (Hocking & Ness, 2002).

FIELDWORK SETTINGS AND MODELS

Traditionally, fieldwork has taken place in the context of a hospital or primary health care setting, in which students spend six weeks to three months at one facility with a single supervisor. However, a number of factors, such as increasing demand for occupational therapy services, personnel shortages, and increasing needs for student placements, are influencing the profession to develop and expand innovative fieldwork opportunities (AOTA, 2000; Thomas, Penman, & Williamson, 2005). Academic programs are developing fieldwork in contexts of emerging practice such as community-based day treatment programs, senior centers, assisted living facilities, sheltered workshops, homeless shelters, after-school programs, home health care, rural settings, and international placements (AOTA, 1999b; Johnson et al., 2006). In particular, **project-focused fieldwork** provides a viable approach to developing new programs or resources or, in evaluating existing programs, for prevention or health promotion settings (Fortune, Farnworth, & McKinstry, 2006).

Additionally, various innovative models of supervision have been proposed as approaches to promote self-direction among students and to better equip them to become lifelong learners as alternatives to the model of one-to-one supervision, which can reinforce dependency (Thomas et al., 2005). The development of three models of supervision has been identified: role-emerging, collaborative, and interagency. The impetus for these alternative approaches to supervision is to foster the profession's goal of new graduates being innovative and effective reflective practitioners and critical thinkers (Bonello, 2001). **Role-emerging supervision**, which occurs in a placement in which there is no occupational therapist on site, provides opportunities for students to be more autonomous and independent, promoting increased professional growth. The WFOT Standards (Hocking & Ness, 2002) and the ACOTE (2007) Standards both note that fieldwork can occur in sites where occupational therapy is emerging. ACOTE requires that students in this type of placement receive a minimum of eight hours of supervision each week from a practitioner who has a minimum of three years of experience. Under these circumstances, a member of the facility's staff assumes the responsibilities of day-to-day supervision.

Collaborative supervision is another model used in fieldwork that may entail one or more supervisors working with multiple students "with all participants viewed as more equal partners in the learning process" (Thomas et al., 2005, p. 80). This model encourages students to assume greater responsibility for their learning through peer teaching and mutual problem solving (Ladyshewsky, 1995). In the case of more than one supervisor, it is useful to identify who will serve as the primary supervisor in order to be responsible for managing the overall fieldwork experience, including the evaluation process.

Another approach to supervision is to merge the traditional one-to-one model in an area of emerging practice; this has been described as the **Interagency Model of Fieldwork** (Fisher & Savin-Badin, 2002). In this approach, occupational therapists who have a vision for the development of a new position for occupational therapy work in partnership with community agencies or industry to establish a fieldwork placement. This model is deserving of further study to determine how to offer high-quality learning experiences, including funding the necessary education and training of both fieldwork supervisors and students in order for this model to be successful. Such experiences hold the promise of building skills that will enable individual practitioners as well as the profession to manage opportunities and transitions that lie ahead in the future.

TRANSITION FROM STUDENT TO PROFESSIONAL

The shift from the academic setting to the fieldwork setting is an obvious, yet often underestimated, life change. Occupational therapy students are making the environmental transition from the classroom to the fieldwork setting while simultaneously emerging from the role of student into the role of occupational therapy practitioner. As with any transition, occupational therapy students leaving academia face a process of change from one structure, role, or sense of self to another. The struggle to assimilate into a new environment and to develop a new role can jolt students into disequilibrium, and some students have trouble adjusting to the new role. As is true of all life changes, this disequilibrium can be an opportunity for growth, especially in the context of a supportive supervisory relationship.

This time of transition for students results in changes in assumptions about themselves and the world and requires a corresponding change in behaviors, relationships, learning styles, and self-perceptions. As they move into fieldwork settings, students may begin to reassess their suppositions about occupational therapy, the theories they learned in school, and their views of themselves as practitioners, learners, and individuals. Because individuals differ in their ability to adapt to change and because each student is placed in a different fieldwork setting, the transition has a different effect on each student.

The nature of the fieldwork environment is fundamentally different from that of the academic environment. Knowing and acknowledging some of the distinctions between the two settings can ease the transition and provide students with support to accept the challenges of fieldwork experiences (see Table 26.1). Within the fieldwork environment, the learning focus shifts to the application or implementation of therapy techniques in an applied interpersonal context. Techniques that were introduced in a simulated context now must be mastered and applied with attention to the client's emotional needs.

TABLE 26.1   DISTINCTIONS BETWEEN ACADEMIC AND FIELDWORK SETTINGS

Characteristic	Academic Setting	Fieldwork Setting
Purpose	Dissemination of knowledge, development of creative thought, student growth	Provide high-quality client care
Faculty/supervisor accountability	To student, to university/college	To client and significant others, to fieldwork center and team, to student
Student accountability	To self	To clients and significant others, to supervisor and team, to fieldwork center
Pace	Depends on curriculum, adaptable to student and faculty needs	Depends on clients' needs, less adaptable, shaped by facility procedures
Student: educator ratio	Many students to one faculty member	One student to one supervisor, small group of students to one supervisor, one or two student(s) to two supervisors
Source of feedback	Summative at midterm or end of term, provided by faculty	Provided by clients and significant others, supervisor, and other staff; formative
Degree of faculty/supervisor control of educational experience	Able to plan, controlled	Limited control, various diagnoses and length of client stay, pace of setting and size of caseload varies from setting to setting
Primary learning tool	Books, journal articles, lectures, audiovisual aids, case studies, simulations, technology, Internet	Situation of practice; clients, families, significant others, and staff; may be face to face or electronic (e.g., webcams, e-mail)
Conceptual learning	Abstract, theoretical	Pragmatic, applied in interpersonal context
Learning process	Teacher-directed	Client, self, peer, supervisor-directed
Tolerance for ambiguity	High	Low
Lifestyle	Flexible, able to plan time around class schedule	Structured, flexible time limited to evenings and weekends
Contexts	University or college classroom, online learning	Hospitals, schools, nursing homes, day care centers, day treatment programs, community-based agencies, clients' homes

Abstract questions that are appropriate in the academic environment shift to pragmatic questions to reduce the possibility of error in one's thinking. For example, rather than thinking about a client's function in the kitchen from an abstract perspective, the student has to think about the client's function in the context of a specific kitchen in a certain small apartment and attend to the client's concerns about his or her roles, activities, family, and home environment. Because the student recognizes that his or her actions have an influence on the client's life, tolerance for ambiguity or uncertainty declines during fieldwork.

In the academic setting, students are accountable primarily to themselves, and performance is evaluated on a summative basis through tests, assignments, and grades. Students choose whether to disclose their grades to family or peers, and their performance does not affect others. In the fieldwork center, a student's performance is evaluated on a formative basis and may be observed by the entire

health care team, especially at team meetings. Performance is no longer the private matter that it was at school but is publicly observed because it has direct and critical consequences for clients. Colleagues, clients, and their families may offer meaningful feedback. Although all these opportunities may create disequilibrium or tension, they also constitute new ways in which students learn about themselves and their profession. The broad and diverse experience within the fieldwork setting challenges students to redefine their sense of self.

Fieldwork takes place in a situation over which fieldwork educators have little control. The organizational factors of the health care setting, combined with client care factors, such as the nature and complexity of the client's problem, the length of stay, and fluctuation in the client load, make planning difficult, especially in acute care settings. In settings that provide extended care for clients, however, the fieldwork educators are able to plan ahead, because the client population is more constant and the fieldwork educator knows which clients will be available during student placements.

Fieldwork educators' primary responsibility is client care; they have an ethical imperative to ensure the welfare of clients. This appropriate professional ethic may constrain activities that are desirable from the standpoint of education. However, the supervisory relationship allows fieldwork educators to adapt to the constraints of the setting. This unique relationship is a positive aspect of the fieldwork environment because fieldwork educators can adapt the fieldwork experiences to meet the learner's needs.

Examination of supervisors' perceptions of successful fieldwork students showed important themes of active experimentation as part of the learning process, including adaptability and doing, as well as being flexible and engaging in teamwork (Herzberg, 1994). A literature review on fieldwork success identifies a number of positive attributes to promote student participation (Sladyk, 2002, p. 8), as summarized in Box 26.1. Awareness of these attributes

and characteristics, in addition to positive coping strategies, can aid students in preparing for and participating in their fieldwork placements.

Exploration of students' coping strategies and their perceptions of fieldwork has shown that a majority of students view the experience as important, while more than half found the experience to be stressful (Mitchell & Kampfe, 1993). Level II fieldwork students invested significantly more effort in the positive coping strategies of being problem-focused, making a plan of action and following it, and seeking social support to obtain information, advice, or emotional support. These results verify healthy approaches and "coping skills for dealing with fieldwork transition and stress" (Mitchell & Kampfe, 1993, p. 537). Students less frequently used negatively regarded strategies such as blaming, wishful thinking, or avoidance, implying that students have healthy coping skills available to them to support their participation in the transitions associated with fieldwork.

An **occupational adaptation model of professional development** as applied to Level II fieldwork outlines three classes of adaptive response behaviors: primitive, transitional, and mature, which are typically demonstrated among all students (Garrett and Schkade, 1995). When faced with situations that they perceive as too difficult or too unfamiliar, students tend to revert to lower-level behaviors. This model can be a useful resource both for fieldwork students, to self-assess their own behavior, and for their supervisors, to help understand the implications and timing for increasing workload assignments and providing new learning challenges during fieldwork.

ROLES AND RESPONSIBILITIES OF STUDENTS AND EDUCATORS

After completion of the prerequisite academic coursework, occupational therapy and occupational therapy assistant students are eligible to begin their fieldwork experiences.

BOX 26.1 **POSITIVE ATTRIBUTES OF SUCCESSFUL FIELDWORK STUDENTS**

- Showing interest in the area of practice and the profession
- Demonstrating concern for the client's needs and issues
- Regarding safety as a priority
- Taking responsibility for one's attitude and behaviors
- Managing time
- Adhering to timelines and due dates
- Seeking additional information

- Practicing skills
- Listening
- Using supervision time effectively
- Exchanging feedback with one's supervisor
- Accepting criticism
- Avoiding excuses
- Exploring new approaches or projects
- Engaging in creative problem solving

Sladyk (2002).

Generally, academic fieldwork coordinators are responsible for administrative arrangements to support students' participation in fieldwork experiences, commensurate with the goals of the curriculum as well as with the policies of affiliated practice settings and health care systems. Clearly defined objectives and guidelines help students to organize their efforts toward achieving professional competence. Working toward mastery of the entry-level skills required for high-quality client care is a mutual undertaking between the fieldwork educators and the students. Both assume primary responsibility for the process of evaluating students' progress and modifying the learning experience within the environment, in consultation with the academic fieldwork coordinator, as appropriate. See Table 26.2 to gain insight into how each person contributes to and participates in the overall fieldwork process.

Fieldwork Educator Guidelines

The role for the people who are responsible for supervising students is formally titled *fieldwork educator,* although the terms *clinical educator, fieldwork supervisor,* and *student supervisor* are also commonly used (AOTA, 2000). The people who are responsible for the fieldwork education program and direct supervision of occupational therapy students must be occupational therapists who meet state practice acts and regulations and have a minimum of one year of practice experience, subsequent to the requisite initial certification (ACOTE, 2007; CAOT, 2005). For occupational therapy assistant students, supervision can be provided by a registered occupational therapist or a certified occupational therapy assistant, also with a minimum of one year of experience. Although the minimum require-

ment is one year of experience, fieldwork educators should be competent practitioners who can serve as good role models or mentors for future practitioners. Ultimately, the fieldwork educator strives to develop and provide the best opportunity for the implementation of theoretical concepts offered as part of the academic educational program while creating an environment that facilitates learning, inquiry, self-direction, and reflection on one's practice.

Fieldwork Evaluation

Frequently, students receive informal feedback during supervision meetings; however, formal mechanisms for providing feedback and evaluation of a student's performance, judgments, and attitudes are built into the fieldwork experience. Fieldwork evaluation has two distinct purposes. One is the formative, ongoing process of directing student learning throughout the fieldwork experience; the other is summative, documenting the level of skills attained at the completion of the fieldwork experience. Although these two processes are different, they are not mutually exclusive. The formative process occurs throughout the fieldwork experience so that students and fieldwork educators can compare perceptions, assess which student activities are important and which are less so, review objectives, plan new learning opportunities, and make necessary modifications in behaviors. The second process, which is cumulative, requires documentation of a student's performance at the midpoint of the placement and after completion of the fieldwork experience.

In the United States, the Fieldwork Performance Evaluation for the Occupational Therapy Student (FWPE/ OTS) (AOTA, 2002b) and the Fieldwork Performance

---

TABLE 26.2 ROLES AND RESPONSIBILITIES IN FIELDWORK

Roles	Responsibilities
Academic Fieldwork Coordinator (AFWC)	◆ Serve as a liaison and collaborator with faculty and fieldwork educators to ensure integration of curricular goals with fieldwork (ACOTE, 2007) ◆ Select training sites and assigns students ◆ Oversee administrative requirements, such as contracts and student health records ◆ Available for consultation to fieldwork educators and students
Fieldwork Educator	◆ Meet requisite eligibility for supervisory role, as applicable (ACOTE, 2007; Canadian Association of Occupational Therapy, 2005) ◆ Engage in administrative collaboration with AFWC to determine and schedule assignments ◆ Provide day-to-day student supervision ◆ Complete evaluation of student performance, as designated ◆ Structure learning and create a positive learning environment
Student	◆ Fulfill all duties identified by the fieldwork educators and academic fieldwork coordinators within the designated timelines ◆ Comply with the professional standards identified by the fieldwork facility, the education program, and the Occupational Therapy Code of Ethics (AOTA, 2005)

Evaluation for the Occupational Therapy Assistant Student (FWPE/OTAS) (AOTA, 2002a) are companion instruments, adopted by AOTA's Commission on Education in 2002 (Atler, 2003). Apart from a numeric rating system, the forms provide space for supervisors to add or qualify their scoring with written descriptions and comments (Atler, 2003). The intent of the fieldwork evaluation is not to differentiate between students, but to measure their achievement of specific entry-level competencies. A profession usually defines its boundaries by setting up criteria for entry. In occupational therapy, the fieldwork experience is an essential component of the entry criteria. Successful completion of Level II fieldwork is a requirement for certification as a registered occupational therapist (OTR) or certified occupational therapy assistant (COTA) (National Board for Certification in Occupational Therapy, 2007). Fieldwork provides students with situations in which to practice interpersonal skills with clients and staff and to develop characteristics that are essential to productive working relationships (AOTA, 2000). Future employers want assurance that students satisfy the entry-level requirements. The FWPE data may be synthesized to provide the foundation for employment references.

Internationally, there is a trend toward the use of standardized approaches for the evaluation of student fieldwork performance. The Competency Based Fieldwork Evaluation for Occupational Therapists (CBFE-OT) (Bossers, Miller, Polatajko & Hartley, 2001), widely used across Canada and the United Kingdom, is designed for use in any level of fieldwork and within any placement area. This instrument is used in conjunction with a learning contract associated with each competency. In Australia, eight out of ten academic programs have adopted the use of the Student Placement Evaluation Form (SPEF) (Allison & Turpin, 2004; University of Queensland, 1998). A unique aspect of this tool is banks of items, grouped according to types of practice settings, from which supervisors can select the most relevant learning objectives and items for evaluating student performance. It is noteworthy that each of these fieldwork evaluation tools is intended to be used across and within all practice settings. Furthermore, similar content and competency areas are evident among these tools, as noted in Table 26.3.

Student Evaluation of the Fieldwork Experience

Students also have the opportunity to provide the fieldwork educators and the fieldwork facility with feedback. AOTA (2006) recommends the Student Evaluation of Fieldwork Experiences (SEFWE) form. This form allows students to provide feedback about orientation, caseload, occupational therapy process; theory, frames of reference, and models of practice; fieldwork assignments; supervisor interactions; aspects of the environment, such as team relationships; and how the entire learning experience related to the academic curriculum and their own professional development. The fieldwork sites use this information to improve fieldwork programs, and the academic programs share the information with future students who are interested in training at those sites. In Canada, a similar form is used for students to provide feedback to fieldwork sites. Overall, documentation of students' feedback regarding their fieldwork experiences is information that is valuable to both the training site and the academic program.

CONCLUSION

Fieldwork is the beginning of a lifelong process of connecting theory with practice. The depth of the experience depends greatly on the degree to which students and fieldwork educators share the responsibility for teaching and learning. Today's rapidly changing health and human service delivery systems are providing new opportunities for occupational therapy practice and fieldwork education. Globally, the profession is giving attention to innovative approaches to improving the quality of fieldwork while taking into consideration each country's health, economic, educational, and social status (Bonello, 2001). To be successful in these dynamic and complex situations, practitioners must be able to make judgments based on thoughtful inquiry, analysis, and reflection on practice in order to support their clients in improving their participation in daily and social activities and overall quality of life.

ACKNOWLEDGMENT

PROVOCATIVE QUESTIONS

1. How can the profession reconcile the tension between the evolution of fieldwork in emerging practice, where there might not be an occupational therapy supervisor on site, and the trend for increased regulations requiring direct supervision, such as Medicare in the United States?

2. You are a student who is interested in a Level II fieldwork placement opportunity working in a health and wellness setting. However, your academic program has established fieldwork arrangements with only hospitals, schools, and private health care facilities. How might you proceed to communicate your learning goals and develop a plan of action to explore the feasibility of developing a new type of Level II fieldwork experience?

Questions for Occupational Therapy Practice

JOHN WHITE

Learning Objectives

After reading this chapter, you will be able to:

1. Describe examples of current practice from individual to population-based occupational therapy.
2. Reflect on and discuss key questions that help to inform decisions about current and future occupational therapy practice.
3. Develop questions that support critiques of current occupational therapy practice.
4. Identify possible directions for the development of future occupational therapy practice.
5. Describe threats and opportunities to the future development of occupational therapy.
6. Identify and describe who is optimally served by existing occupational therapy resources and how those services will best be delivered and distributed.

"**D**welling in possibilities" is as natural to practitioners of occupational therapy as is the belief in the link between occupation and health (Meyer, 1977; Rebeiro, 2001; Wilcock, 1993, 1998a, 1998b; Yerxa, 1998). Occupational therapy confronts limitations that environments, circumstances, impairments, policies, and sociocultural situations place on people and imagines possibilities for creating full and satisfying lives. In this chapter, we will explore visions of possible futures for occupational therapy from individual and organizational perspectives.

OPENING QUESTIONS

How are we doing as a profession at creating possibilities for the clients who most need our services? Are we doing our best? If not, what is holding us back? Who is being served through our activities: clients, health care systems, third-party reimbursers, ourselves? Where are we going in the future? This chapter addresses these and related queries in order to prompt therapists to reflect on the relevance of our current practice and how well it corresponds to the most appropriate needs of those we serve. In addressing these questions, occupational therapy practice in the United States will be the primary reference point, but examples of practice in other countries will also be used. I will first address examples of change in the field and then identify some significant threats to our viability. Throughout the chapter, I will pose questions for reflection as we move forward into a rapidly changing future.

RAPID CHANGE

Society is changing at a dramatic and unpredictable pace and increasing in complexity in areas such as technology, knowledge, politics, and culture. Occupational therapy is part of this "hyperchange"—change that is rapid, unpredictable, chaotic, and turbulent (Hinojosa, 2007; Weiner & Brown, 2006). In the 30 years that I have been in practice, especially in the last 15 years, there has been an explosion of changes in occupational therapy. These changes have occurred in occupational therapy education and practice as well as in health care, policy, and technology. We will consider examples of changes in theory, research, and technology.

Some of the change in occupational therapy education and practice has been driven by changes in occupational therapy–related theories. For example, many of the theoretical changes and some of the changes in practice have been fueled by the advent of **occupational science** (e.g., the theories that are featured in Unit I), as well as new approaches to assessment, intervention, education, and research. Occupational science is only one of many influences on changing theory and practice. Practice and theory in Canada, for example, were prompted to change

by the Canadian health ministry's charge to the national occupational therapy association to develop more client-centered practice guidelines (Law et al., 2005). One outcome was the Canadian Model of Occupational Performance (Law, 1998; Law, Baptiste, & Mills, 1995), which brought the concept of spirituality into occupational therapy's domain of concern (Christiansen, 1997; Collins, 1998; Crepeau, 1991; Egan & De Laat, 1994; Townsend, De Laat, Egan, Thibeault, & Wright, 1999; Urbanowski & Vargo, 1994) and ensured a process for person-centered assessment and intervention.

The approach to conducting and using research in occupational therapy changed dramatically with the advent of evidence-based practice (EBP) as a modified form of evidence-based medicine (EBM). Though EBM was first introduced in the 1970s (Cochrane, 1972), it did not have a significant influence in occupational therapy until the late 1990s. EBP began at that time in the United Kingdom (Culshaw, 1995; Eakin, 1997) and spread rapidly to the United States and Canada (Hayes & McGrath, 1998; Law, 1998; Ottenbacher & Maas, 1999). EBP is now becoming a driving force in occupational therapy education and practice (Baum, 2006; Corcoran, 2006) and in other fields. I explore questions concerning EBP later in this chapter.

In the realm of changing technology, home or office-based computers still seemed like science fiction in 1976, yet less than 10 years later, I was using simple cognitive retraining programs on an Apple® computer and learned about a voice-recognition system that cost $25,000 (similar software now retails for about $100). Assistive technology today is evolving faster than many therapists can keep up with, and technological innovation is making participation in a range of occupations possible for people with disabilities that were only dreamed about 20 years ago (Cate & Perez, 2004; Gentry, 2005; Lange & Brians, 1995). How do we best incorporate technology in our field, which has long celebrated the human-to-human connection?

Changes in technology, the role of EBP, and theories are only a few of the many examples that have potentially profound effects on the profession and the status of practice. When we consider the combined force of all the possible global and local changes that affect practice, we begin to see the influence of hyperchange. Change is often said to be good for us, but it is usually challenging, and it can be threatening if we feel that our security or established routines and roles are at risk. If some change is good, is hyperchange better—or just more threatening? Our response is largely determined by how prepared we are to cope with, and adapt to, the changes. "Futurethink" or anticipatory thinking and problem solving, is an approach that Weiner and Brown (2006) recommend as the most effective way to avoid the stresses and negative outcomes in the midst of the turbulent events surrounding hyperchange. Following are some steps in futurethink:

1. Conduct a thorough analysis of the situation by asking good questions, and don't just look for the answers

that you hope to see, but look for the ones that are there in reality.

2. Look for the big picture in its most holistic context by linking events and trends for the broadest patterns and key connections.

3. Link information to action. Once you understand the big picture in its full context and have an idea of how to proceed, take action to implement the solution in order to avoid blocks that lead to inaction (Weiner & Brown, 2006).

THREATS TO PRACTICE

Considering the extent of current change, it might be that change itself is a threat to the profession. We will now analyze some external and internal threats to occupational therapy.

External Threats

External threats to the success of the global profession are most easily identified. These threats warrant action if we are to fulfill our "potential to create a significant impact on tomorrow's world" (Yerxa, 2003, p. 979) by promoting a "new concept of health" that promotes agency and participation for those we serve (Yerxa, 2003, p. 978). One of the biggest external challenges to sustained growth and success in occupational therapy is the source of payment for occupational therapy services, whether in free-market or government-sponsored health systems, along with the ever-growing pressure and related ethical challenges to increase therapist productivity (Howard, 1991; Slater, 2006). For example, in the United States, reimbursement for rehabilitation services in skilled nursing facilities was severely curtailed in 1999. In that case, government policy was primarily responsible for significantly decreased payment for services (Daus, 1999). This change in payment for services followed close behind changes in health care systems, such as the advent of managed care practices (Christiansen, 1996). These professional crises (Baptiste & Martin, 1994; Fine, 1998; Wood, 1998) were preceded by a constantly changing approach to reimbursement by federal, state, and private insurers that have dictated what work occupational therapists would and would not be paid for (Walker, 2001). Tighter budgets for therapy services drive the need for greater productivity in terms of "treatment units" (the unit of intervention time that is charged to the client's account) ever higher. A different sort of resource crisis occurs in some developing nations when occupational therapists leave their native countries to pursue practice in nations where salaries are much higher, sometimes after being recruited by companies in developed countries (Sinclair, 2005). Considering our commitment to ethical, high-quality service, what is our response to a trend that is essentially taking from the poor to give to the rich? How do we balance the individual freedom to practice where one chooses with the need to provide services where they are most needed?

Professional "turf" competition, often played out at the professional licensure level, is an increasing threat as other professional groups claim practice areas that have traditionally been held sacred by occupational therapy (see the "practice alerts" section on www.aota.org for various turf issues). These are certainly challenges that must be addressed by the members of the profession through individual and organizational activity and advocacy. When challenged in this way by groups that feel that they can do work that occupational therapists have traditionally claimed, it is critical for us to ask ourselves, "What are we doing that is unique to occupational therapy and not redundant to related professions?" For example, what can make hand therapy a unique and obviously a special part of occupational therapy? There are examples of occupation-based hand therapy in the literature that begin with client-centered assessment (Amini, 2004; Earley & Shannon, 2006). Will they prove to be uniquely occupational therapy and simultaneously more effective than more pathology-focused approaches? What differentiates occupational therapy service in a long-term care facility from activity therapy or physical therapy (Atwal, 2003) or makes it distinct from social work in a community mental health program (Rebeiro, Day, Semeniu, O'Brien, & Wilson, 2001)?

Considering innovative and emerging practice models from international examples, how are our resources best applied to relatively new populations? New models of practice are seen with occupational therapy for children who survived war in Kosovo (Algado & Burgman, 2005), and advocating and promoting participation through play for children with HIV/AIDS in South Africa (Ramugondo, 2005). Yet one more example is through power-sharing, using approaches such as community-based rehabilitation (CBR), which applies traditional rehabilitation approaches in community settings to address **occupational apartheid** and **occupational deprivation** (Kronenberg & Pollard, 2005).

If we can successfully address the questions in this section, we should be able to avoid the risk that Mary Reilly identified when she described a potential dilemma for the profession in that the need for occupationally relevant services will always exist, but it is up to occupational therapy to make the most of its unique contribution to society to ensure the profession's survival. Reilly asserted that even if occupational therapy were to fail as a profession, another similarly situated group would emerge to "serve society's need for action" (Reilly, 1962, p. 2).

However, as significant as these examples of external threats are, if we allow internal professional threats to prevent us from developing our fullest potential to serve those who most need our services, there will be little force or structure that we can use to find ways to meet the external challenges.

Internal Threats

What internal forces threaten to diminish our effectiveness in a world of need for our services? A few examples to be explored here are the question of unification versus diversification, the tension between general practice and specialization, and the role of professional associations. A search for agreement about our common purpose, core values, and unifying theory is perhaps one of the most significant challenges with which occupational therapists have wrestled for at least the past 30 years (Engelhardt, 1977; Hocking, Whiteford, Henare, & Hansen, 1995; Kimura, 1987; Nelson, 1997; Polatajko, 2006; Whiteford, Townsend, & Hocking, 2000). Do we gain more strength, credibility, and value as a profession through the diversity of many approaches to practice, or will we benefit more from a universal approach?

Occupational science has contributed to the search for a common unifying core that began with a spirited debate about whether the new discipline should be partitioned off from occupational therapy (Clark et al., 1993; Mosey, 1992, 1993). Time has shown that increasingly, the evolution of the science and therapy are intricately intertwined, leading to new theories, applications, and research endeavors. There is a growing global presence in that there are now at least eight societies promoting various aspects of occupational science that are influencing occupational therapy practice worldwide (see http://isos.nfshost.com/links.php).

How ultimately successful the interaction between occupational science and occupational therapy will be has yet to be determined, but several examples demonstrate early influences. One is the landmark USC Well-Elderly Study (Clark et al., 1997; Mandel, Jackson, Zemke, Nelson, & Clark, 1999), which demonstrated the value of occupational therapy interventions enhanced by occupational science research to improve health and life satisfaction in community-dwelling elders. Another example of the influence of occupational science on practice is evident in the change in focus of national conference presentations in North America, the United Kingdom, and the World Federation of Occupational Therapy (WFOT). Before the development of doctoral and other occupational science programs since 1989 (Clark et al., 1991; Yerxa et al., 1989), the use of the term *occupation* in national occupational therapy conference papers was rare. *Occupation* is now featured prominently in program titles, yet the challenge to develop a universally agreed-upon definition of *occupation* and its distinction from *activity* persists (American Occupational Therapy Association, 1995; Baum & Edwards, 1995; Evans, 1987; Pierce, 2001; Wilcock & Townsend, 2000; Wu & Lin, 1999). Entry-level educational programs are incorporating occupational science into curricula in hopes of preparing students to better understand and apply occupation in practice (Behr, Bass-Haugen, Gordon, Bennett, & Henderson, 2003; Hender-son, 2004; Hilton & Randolph, 2003; Wilcock, 2003; Wood et al., 2000). Finally, professional associations in several countries have adopted practice guidelines that reflect the influence of occupational science research and theory development (College of Occupational Therapists, 2004; Youngstrom et al., 2002). The summary question arising from this discussion is: Will occupational science be a force that is capable of uniting the occupational therapy profession through its international focus on understanding occupation and promoting new and more effective approaches to applying that understanding in practice?

Specialization is another phenomenon that could be a strength or could present a potential threat to the profession. While helping individual practitioners to develop the expertise they need to address highly complex specific problems, specialization can also dilute a common professional identity and potentially lead to a scramble for resources. The debate is not unique to the United States and is linked to the power of the national occupational therapy organizations to control the issue of specialization (Chacksfield, 2006; Crawford-White, 1996; Cromwell, 1979; Knutsson, 1980). Former American Occupational Therapy Association (AOTA) president Mary Foto presented a comprehensive review of arguments for and against specialization that have been extant in the United States since at least 1952. She proposed a compromise position in which the profession could embrace "specialists, generalists, and assistants." However, much work is still needed to clearly define the different roles and develop clear competencies for each (Foto, 1996). Foto proposed that such work would most appropriately be done by AOTA.

AOTA has apparently responded to Foto's recommendation through the development of board certifications in various practice areas such as mental health, pediatrics, and physical rehabilitation, as well as certification in specialty practices related to driving, low vision, and dysphagia (AOTA, 2007). Other organizations also offer specialty certifications with widely varying criteria for earning the certificate. For example, the American Society of Hand Therapists (ASHT) supports certification in hand therapy through a rigorous and lengthy process (American Society of Hand Therapists, 2007; Hand Therapy Certification Commission, 2007). Some for-profit companies offer certification in specialized testing techniques such as the Sensory Integration and Praxis Test (Western Psychological Services, 2007) or treatment procedures such as lymphedema management (Coast to Coast School of Lymphedema Management, 2007). What are the implications for such specialization, and who is being optimally served through these certifications? At what point does a person become a hand therapist or lymphedema specialist and lose his or her identity as an occupational therapist? If the specialist is helping the client, does it matter what professional name is used to identify the therapist? Would the client be served better if the specialty were delivered through the context of authentic occupational therapy (Wilcock,

1998a; Yerxa, 1967)? We must also ask ourselves about the legal and ethical issues that arise when a person who is certified as an occupational therapist is providing services that have little resemblance to occupational therapy, but are being charged in the name of occupational therapy. I believe that the name under which one practices and the kinds of practice one performs do matter and that specialization should add value to a service that is delivered in keeping with the guiding principles of occupational therapy, not supplant or replace it so that the professional identity as an occupational therapist is lost.

Threats can be the paradoxical side of strength. Such is the case with professional associations that are generally seen as a strength in advancing the field but can also be seen as holding back progress through entrenched traditions and bureaucracies. What are the most appropriate roles of our professional organization in helping us face a rapidly changing world? Hinojosa (Hinojosa, 2007) suggested that if we are to flourish in an age of hyperchange, we will need to consider challenging questions related to the structure of our professional organizations, more critically and rapidly scrutinize our practices, and create innovative paradigms to cope with rapid social and scientific change. One way in which AOTA is charting a course for the future of occupational therapy in the United States is through development and promotion of a Centennial Vision for 2017 that states, "we envision that occupational therapy is a powerful, widely recognized, science-driven, and evidence-based profession with a globally connected and diverse workforce meeting society's occupational needs" (AOTA, 2006) with suggested actions to accomplish these goals. Does this vision capture the unique nature and contribution of occupational therapy? If so, will such a vision be adequate to meet the challenges of hyperchange? Is the profession prepared to step up to do the work that is needed to be ready to embody the vision? In taking action, will the profession practice good "future-think" (Weiner & Brown, 2006)? For example, will our professional associations push us to unquestioningly embrace evidence-based practice as a key to professional validation?

Evidence-Based Practice

One factor that has been imposed from outside the field but is being supported by professional organizations and adopted in practice is that of evidence-based practice (Holm, 2000, 2003). What began as an epidemiologist's proposal to use appraisals of relevant medical research to guide systematic decision making (Cochrane, 1972), eventually called evidence-based medicine (EBM), has grown into a worldwide phenomenon that most health care professions have adopted as the singular most important hallmark of best practice. The EBM agenda promotes effectiveness, efficiency, and equality in the delivery of health services and grew out of a social ethic of care and

equitable distribution of services (Cochrane, 1972). Other fields, including occupational therapy, adopted an approach related to EBM called evidence-based practice (EBP). EBP clearly has the potential to improve clinical decision making and foster the growth and acceptance of the field of occupational therapy. However, there is a risk inherent in the rush to embrace EBP that threatens our ability to demonstrate the effectiveness of our outcomes. That risk occurs when we uncritically adopt the hierarchy of levels of evidence, and it is compounded when the client's perspective is ignored (Coster, 2005; Sudsawad, 2006).

Fortunately, there are leaders in the EBM/EBP fields who are promoting a more integrated approach to EBP. This approach helps practitioners and researchers to value the client's collaboration in the clinical decision-making process and rely on their own practice expertise while appraising the best scientific evidence available. David Sackett, a leader in the practice and teaching of EBM, and his colleagues have updated the definition thus: "Evidence-based medicine (EBM) is the integration of best research evidence with clinical expertise and patient values." (Sackett, Straus, Richardson, Rosenberg, & Haynes, 2000, p. 1). They emphasize that practitioners must incorporate the patient's unique expectations, preferences, and concerns if practice decisions are to truly serve the individual.

Qualitative methodologies can be one form of research evidence that informs practitioners of client values and experiences (Sackett et al., 2000; Sudsawad, 2006; Tickle-Degnen & Bedell, 2003; Whiteford, 2005, 2007). However, qualitative studies are still considered to be at the lowest level in the hierarchy of levels of evidence (Mykhalovskiy, & Wier, 2004; Tickle-Degnen & Bedell, 2003; Whiteford, 2007). Evidence-based medicine is appropriately reliant on strict quantitative scientific method to study questions of pathophysiology. However, those reductionistic methods are likely to fall short in studying the complex phenomena associated with human behavior, meaning, and occupation. In a strict EBP approach, qualitative research methods that are more descriptive, narrative, or interpretive in nature are more easily discounted, and the credibility of much of the core of occupational therapy service (i.e., restoration of a meaningful life of action (Yerxa, 1991, 1998)) is thus diminished.

Occupational therapy needs an approach to EBP that supports **integrated practitioners** who use "integrated science." An integrated practitioner is one who considers the best scientific evidence while simultaneously attending to the humanistic aspects of the client's narrative and lived experience (Yerxa, 2005). Whether or not occupational therapists develop such an EBP approach and earn the respect of others in its use will likely depend on our skill in using currently defined best practice, demonstrating the value of our practices with multiple research methods, and collaboratively guiding the change to a more inclusive

model of the types of evidence that are needed in a holistic and integrated field of practice such as occupational therapy.

Across professions, there are calls for new approaches to incorporate multiple methods and factors into the research appraisal process (Clarke, 1999; Kuzel & Engel, 2001; McGuire, 2005; Mykhalovskiy & Wier, 2004; Upshur, VanDenKerkhof, & Goel, 2001). Tickle-Degnen and Bedell (2003) offer an alternative appraisal model in their **heterarchical** approach, which suggests that therapists consider a network of factors for clinical decision making instead of a hierarchy of levels. Humphris (2000) suggests that the levels of evidence be viewed along a continuum in which the significance of the level is determined by the nature of the question or clinical situation being considered. In this approach, the congruity between the research or clinical question and the research methodology takes precedence in appraising the evidence (Ottenbacher, 1992).

Even if more inclusive and integrated models are created, they will be useful only if therapists adopt them as standard practice. McCluskey (2006) describes the barriers to implementing EBP in occupational therapy and the process of managing change in a fast-changing world. How will therapists find enough time and develop adequate skills (the most oft-cited barriers) to integrate EBP into their practices? These challenges cannot be addressed by individual practitioners alone but must be taken on by professional organizations, employers, and educational institutions to attain systematic change in the use of EBP. Occupational therapy theory development also needs to incorporate these concepts to support best evidence-based practice.

Theories and Models of Practice

Our theories themselves, if not constantly questioned, tested from new perspectives, and validated through research and practice, can be limits to our success. Kuhn (1970) argued that fields that tenaciously hold onto inadequate paradigms to support their theories and practices are likely to miss opportunities to envision new and more suitable paradigms, thus risking becoming ineffective. How well do our theories explain our most important phenomena of concern, such as occupation, life balance, adaptation, independence, and performance? How universally can theories that are developed in one country be applied elsewhere? How open are we to consider alternative explanatory theories?

Michael Iwama, an occupational therapist of Japanese ancestry who was raised in Canada, was confronted by just such a paradigm dilemma while on an extended teaching assignment in Japan. The result was the development, with his students, of the Kawa (River) model (Iwama, 2003, 2006). This model was developed because of the difficulty his students in Japan had in understanding and applying some Western concepts and models of occupational therapy and occupational science to their own lives. The Kawa model was built on assumptions about Japanese culture, which is more collectivist, naturalistic, interdependent, and hierarchically structured than is typical in Western cultures, and demonstrates the value of **cultural relativism**. If we envision occupational therapy becoming universally relevant, we must understand the cultural implications of our understandings of occupation and intervention (Iwama, 2005) and be open to reinterpreting or revising them. Iwama's own questions prompt important challenges for consideration:

> With whose cultural norms do we view our clients—especially those clients who fall outside of our conceptions of the normal? Do our current epistemologies, ideologies, theories and practice in occupational therapy truly abide within the lived realities of those we serve? To what extent do occupational therapists situated outside of the mainstream social spheres of experience participate in our knowledge production and discourse? (Iwama, 2005, p. 252)

Many other commonly used occupational therapy concepts need such critical scrutiny. Balance is one such idea that needs elaboration through research and theory development as well as a means of clearly applying it in practice, should it prove useful. Early work is being done to examine what life balance is (Blessing, 2004; Matuska & Christiansen, 2003), how to measure it (Erickson & Matuska, 2006; Matuska & Christiansen, 2003), and how to use it in practice (Davis, 2004). Occupational therapy has repeatedly emphasized the importance of independence as a goal of practice, yet the concept has not been fully explicated or researched. Alternatives to independent functioning such as the notion of interdependence (Gage, 1997; Higgs & Titchen, 2001) are emerging, especially as occupational therapists consider more inclusive cultural views (Iwama, 2006). Occupational justice is a relatively new idea that demands greater cultural competence and is providing a means of considering population-based occupational therapy.

OCCUPATIONAL JUSTICE

If we have difficulty in understanding the cultural differences of our clients, how well will we be able to serve them? So far in this chapter, the question of who is being served has focused more on the individual, the traditional unit of interest in occupational therapy. However, with the advent of the concept of occupational justice (Townsend & Wilcock, 2004; Wilcock, 1998b), occupational therapists are increasingly considering larger groups and entire populations in terms of opportunities for occupation and the social, cultural, political, economic, and geographic

factors that control or affect access to participation. Significant numbers of the world's population experience occupational deprivation, the lack of opportunity to participate in needed or desired occupations; for example, over half the people of the world are malnourished and lack basic health care (World Health Organization, 2002). When such basic needs are not met, it is difficult to pursue higher-level needs (Maslow, 1943), ones that are usually associated with occupational fulfillment. People who are experiencing disability are often deprived of occupational opportunities either related directly to the impairment underlying the disability or, in many cases, due to the social construct of disability (Beer, 1998; Higgins, 1992; Liachowitz, 1988) in which political, attitudinal, physical, or social barriers limit occupational opportunities.

Often when I am teaching about occupational justice, students or therapists seem to be inspired by the concept of improving justice in the world through occupational therapy. However, a common question arises: "With so much need for occupational therapy in traditional settings, why should we be looking to do this kind of work?" My response is that once a practitioner has embraced the basic philosophy of the profession, (i.e., that occupational engagement and meaningful occupation are essential for health and well-being (Wilcock, 1998a, 1998b) and the environment either supports or constrains occupational performance), it is difficult to think about how occupational therapy would *not* be used to promote occupational justice. In other words, occupational justice is fundamental to our practice. Furthermore, whenever the occupational therapy process is used to help a person achieve occupational goals, it is assumed that occupational deprivation is remediated or prevented and thus occupational justice is advanced for that person.

What is our responsibility for addressing the problems of the world's people who are "constrained, deprived, and alienated from engaging in occupations that provide personal, family, and/or community satisfaction, meaning and balance through what they do" (Wilcock & Townsend, 2000, p. 85)? Do we accept the charge from the World Health Organization to "respond to each individual's spiritual quest for meaning, purpose, and belonging" along with the individual's rights to employment, rest, and leisure (World Health Organization, 1998, p. 2) by promoting participation and supporting pursuit of meaningful activities, that is, by applying an occupational therapy process to help correct injustices in these areas? If we, as an international profession do embrace occupational justice, there are many challenges to its admittedly utopian vision. However, if we are not in pursuit of an ideal world, we risk settling for less than the best of what occupational therapy has to offer.

There is, however, a growing awareness of occupational justice through publications and projects on health disparities (Braveman, 2006; Ford, Waring, & Boggis, 2006). International attention to the occupational justice–related projects featured in *Occupational Therapy Without Borders: Learning from the Spirit of Survivors* (Kronenberg, Algado, & Pollard, 2005), as well as WFOT's adoption of CBR (Kronenberg, 2003), are useful examples. Currently, occupational justice is best known in circles of educators and those who are actively involved in international professional activities. Therefore, a key question to consider is whether or not concepts related to occupational justice will eventually be adopted by mainstream therapists and incorporated into what Kronenberg has called **political activities of daily living** (Kronenberg & Pollard, 2005). "The availability of occupational justice is determined by political factors in the occupational environment" (Kronenberg & Pollard, 2005, p. 67), and Kronenberg believes that those with political freedoms must take political action at whatever level is available to them to help resolve occupational injustices. The practice of political activities of daily living extends beyond writing letters to lawmakers, raising funds for a political cause, or voting regularly, as important as those activities are. Understanding the political nature of human relations and societies and then embodying that understanding so that political awareness and action for justice become activities of daily life is a key to achieving occupational justice.

When considering occupational justice in occupational therapy, one envisions practice as applied to large populations, although the concept does apply to individuals as well. However, to achieve the ambitious goals of an occupational justice vision, by thinking and working at the population level, occupational therapy can have a much greater impact than its usual focus on the individual. Yet what will it take to create a critical mass of therapists who view practice in this way to be able to realize significant gains for a more occupationally just world? How significantly will the educational process need to change for occupational therapists? Can it be integrated into an already crowded curriculum in a way that still allows graduates to competently enter more typical practice areas? Does occupational justice present a threat to the profession through taking the focus off our traditional unit of interest (the individual), or does it offer a potential boon by reaching greater numbers of individuals through population work, thus demonstrating greater value to society? Would an occupational therapist working strictly at the policy level in a national government still be doing occupational therapy? If he or she is promoting occupational justice through the policy work, does it matter? These are among the questions for pondering and reflection.

SUMMARY

This chapter provided an overview of occupational therapy practice with examples that present a small sample of the incredibly wide range of ways in which occupational therapy is practiced and pose many questions (and a few answers), designed to assist us in appraising the status of

the field currently and into the future. The chapter began with an eye toward the many possibilities that exist for the profession, then examined some of the factors that threaten our realization of those possibilities. Throughout, we periodically considered the question of who is being served by our actions, which is perhaps the most crucial question we should continuously be asking ourselves.

The overview that was presented here is designed to help in creating a big picture of occupational therapy practice. A big picture, yes, but within the confines of this brief chapter, it is a necessarily incomplete one. Keeping an accurate vision of the big picture is one of the three steps that are recommended for successfully coping with the hyperchange (Weiner & Brown, 2006) in which we are all immersed. In keeping with that recommendation, I encourage you, the reader, to seek to complete this big picture of practice through your reading of this text and the many other sources of information about practice and international occupational therapy. Join your state and national association, as well as the World Federation of Occupational Therapists. Attend conferences to meet others in your field and hear firsthand your fellow occupational therapists' stories of research, practice, theory, and dreams. In doing so, you will likely learn, as I have, that the big picture of occupational therapy is ever changing, ever growing. Understanding the big picture of occupational therapy is like the view from an airplane leaving the earth: You see more and more of the world, but the more you take in, the more there is to see, and you realize that you will never get the whole picture—but how much fascination there is in seeking it!

I hope that you are prompted to reflect on these questions and press yourself and your fellow students and colleagues for answers and to use those answers to help chart the future of the profession. So I will leave you with two final questions:

1. What possibilities will occupational therapy realize?
2. What constraints and threats will we allow to hold us back or face creatively and adaptively to realize the promise of our unique field?

PROVOCATIVE QUESTIONS

1. Where does the greatest potential lie for occupational therapy to realize its greatest good for society? How should the profession pursue that potential?
2. Assuming that the current models of EBP do not optimally serve occupational therapy practice, what form of EBP will best serve the development of occupational therapy?

OT Values and Beliefs in Action

"We are smart, talented people who have a passion to improve the lives of those we serve. We can provide leadership to our institutions, our communities, and to society. The work we do is so important."

M. Carolyn Baum

Ethical Decision Making in Occupational Therapy Practice

REGINA F. DOHERTY

" The tools of ethical decision making include developing 'habits of thought' for reflection on complex, changing situations that are part of everyday practice. "

—JENSEN (2005)

Learning Objectives

After reading this chapter, you will be able to:

1. Recognize the ethical issues that occupational therapy practitioners encounter in clinical practice.
2. Understand basic ethical theories and approaches to ethics.
3. Understand and apply an ethical decision-making guide for case analysis.
4. Understand and apply ethical reasoning as a construct within the clinical decision-making process.
5. Identify and know how to access ethics resources.
6. Understand effective communication strategies for difficult conversations.

WHY ETHICS?

Ask yourself the following questions:

- What would I do if a client told me that he had stopped taking his medication but he didn't want me to tell his doctor because the client had been giving the prescription to his girlfriend who "needs the drug more" but cannot afford it?

- How would I feel if the family of an infant with Down syndrome told me that they wanted to discontinue the infant's feeding tube because they did not think she would have a good quality of life?
- What would I say to a colleague who asked me to change my documentation to indicate that a client is worse than he really is so that the client can qualify for additional services?

Ethical questions like these often arise for occupational therapy practitioners in their day-to-day clinical practice. These questions must be attended to so that normal care delivery is not disrupted and best practice is achieved. This requires practitioners to recognize ethical situations and to have both the capacity and the willingness to address these situations systematically. This chapter discusses ethical issues that arise in occupational therapy practice. It serves as a foundation to aide the reader in understanding, recognizing, and reasoning through ethical issues. Occupational therapy practitioners in all professional roles will encounter ethical problems. Ethics is about reflecting, thinking, critically reasoning, justifying, acting on, and evaluating decisions. Ethical problems are often dynamic and complex, requiring additional knowledge and consultation with various resources. Consequently, knowledge and understanding of ethical reasoning and decision making are essential for competent occupational therapy practice.

ETHICS, MORALITY, AND MORAL REASONING

The terms *ethical* and *moral* are often used interchangeably in clinical practice, and though related, they have slightly different meanings. The term *ethic*s stems from the Greek word *ethos,* meaning "character." Ethics is a branch of philosophy that involves systemic study and reflection providing language, methods, and guidelines to study and reflect on morality (Purtilo, 2005). In contrast, the term *morality* refers to social conventions about right and wrong human conduct and sets the stage for ethical behavior. Values, duty, and moral character guide reasoning and inform ethical decisions (Beauchamp & Childress, 2001). Values are the beliefs or objects a person holds dear (e.g., life). Duties describe an action that is required (e.g., provide food and shelter to care for ones family). Moral character describes traits or dispositions that facilitate trust and human flourishing (e.g., compassion, honesty) (Purtilo, 2005). There are three types of morality: personal, group or professional, and societal (Glaser, 2005). Personal morality includes individual beliefs and values. Group morality is the morality of the profession or group to which an individual belongs. A professional organization, such as the American Occupational Therapy Association (AOTA), maintains collective values that guide group decisions. For occupational therapists, this might be the emphasis on occupational performance. Societal morality is the morality of society as a whole. Societal values may change over

time, and different communities may fight for the protection of different values and rights. It is important to reflect on how these different types of morality interrelate, because in a pluralistic society, no single vision of morality prevails, making ethical decision making ever challenging.

We use moral reasoning to reflect on ethical issues. Moral reasoning is about norms and values, ideas of right and wrong, and how practitioners make decisions in professional work (Barnitt, 1993). Ethics provides the mechanisms for this reflective process (Purtilo, 2005), which ultimately results in a course of action that practitioners feel is the most ethical to pursue. Ethical practice requires a commitment to personal conduct and an appreciation of its effect on others (Jennings, 2003).

Occupational therapy practice involves collaborating with clients to help them to optimize their independence and quality of life. This work consists of personal encounters that may bring with them difficult situations that challenge the value system of practitioners and society. Consequently, effective moral reasoning and ethical decision making are closely linked to effective practice (Bebeau, 2002; Hartwell, 1995; Sisola, 2000).

ETHICAL IMPLICATIONS OF TRENDS IN HEALTH CARE AND OCCUPATIONAL THERAPY PRACTICE

Health care systems are increasingly complex. New technologies, including those utilized in intensive care, life-sustaining treatment, reproductive medicine, genetics, and organ transplantation, have created ethical dilemmas for health care professionals relative to patient autonomy and the allocation of resources. Improved lifestyle choices, managed care, and changes in health care legislation also complicate occupational therapy practice, increasing the likelihood of encountering ethical dilemmas. Practitioners may face dual obligations regarding clients and the institutions that the practitioners serve centering on limited resources related to health care access and coverage. Tensions between what is good for society as a whole and what is best for the individual also arise in care delivery (Smith, Hiatt, & Berwick, 1999; World Health Organization, 1994). Common ethical issues that occupational therapy practitioners encounter include the following:

1. Confidentiality and disclosure
2. Quality of life
3. Clients' decision-making capacity
4. Personal and professional boundaries
5. Use of power
6. Resource allocation and priorities in treatment
7. Cultural, religious, and family considerations
8. Balancing benefits and harm in the care of patients (Barnitt, 1998; Fletcher, Miller, & Spencer, 1997; Foye, Kirschner, Wagner, Stocking, & Siegler, 2002; Purtilo, 2005).

The most frequently cited ethical issues that rehabilitation practitioners encounter are related to health care reimbursement, conflicts around goal setting, and patients' and/or caregivers' refusal to follow the team's recommendations (Foye et al., 2002). Occupational therapy practitioners often face competing demands between access to care and reimbursement for services. Balancing obligations to both patients and non-patient-related groups (e.g., payers, administrators) is a common struggle, and ethical issues arise when obligations to both cannot be met (Foye et al., 2002; Triezenberg, 2005).

VIRTUES OF HEALTH CARE PROFESSIONALS

Health care professionals hold a unique societal role because the public expects them to uphold particular virtues. These include the virtues of benevolence, competence, objectivity, caring, and compassion (Devettere, 2000; Fletcher et al., 1997; Pellegrino, 1995, 2002; Purtilo, 2005). First, the occupational therapy practitioner must be benevolent and focus on the good of the client. This often requires subordination of self-interest to that of the client. Second, the practitioner must be competent. All practitioners are responsible for achieving and maintaining competence in their area of clinical practice. Third, practitioners must be objective and use evidence to guide practice decisions. Fourth, practitioners must be caring because care enhances comfort and recovery (Fry & Veatch, 2000). While most practitioners recognize that caring is inherent in the health care professional's role, there are times when professionals must deal with difficult clients or families. There may be lack of reciprocity and mutuality caused by the condition itself, such as combativeness resulting from a head injury, which can erode the caring relationship. Erosions in care relationships can also occur when acuity rises and staffing diminishes (Maupin, 1995). Finally, practitioners must be compassionate. Compassion is the ability to enter into the experience of illness with the client (Pellegrino, 1982). Compassion is being kind, understanding, genuine, empathetic, caring, considerate, and professional in carrying out a task or duty. From time to time, all health care providers will experience complex situations and conflicting demands. It is during these times that practitioners must call on both character and conduct to provide compassionate care.

DISTINGUISHING AMONG CLINICAL, LEGAL, AND ETHICAL PROBLEMS IN PRACTICE

Practitioners must learn to distinguish ethical questions from other questions that they encounter in the care of clients. Many times, what might appear to be an ethical issue is in fact something else, such as a miscommunication or a clinical or a legal issue. For example, a clinical question would be "Can clients with severe dysphasia due to end-stage amyotrophic lateral sclerosis (ALS) eat?" This is a clinical question because there is a diagnostic answer to the question. Clients who pass a modified barium swallow (MBS) test are clinically able to eat. If they fail this test but want to continue eating orally, an ethical question could arise. The ethical question would be "Should clients with end-stage ALS who fail a MBS test eat?" This is an ethical question, as it raises questions relative to quality of life and the risks and benefits of eating with diminished swallowing capacity.

Legal questions may also arise in decision making in patient care. Law and ethics are related fields; however, they have different goals and sanctions. Both rely on analytical processes and ground rules for good decision making; however, laws are legislated and are legally enforceable (Horner, 2003). Laws prescribe what we cannot do. What may be permitted legally might not be justified ethically and vice versa. In the case of clients with ALS, a legal question would be "Do competent clients have the right to refuse medical advice and continue eating orally despite the recommendation of the team?" This example highlights the importance of distinguishing the type of question to more critically reason through the problem.

Reflection and Ethical Practice

Recognizing the morally significant features of a situation is the first step in ethical reflection. Reflection is a form of self-assessment that can be used to improve practice. Developing reflective capacity is a critical element in professional development and competence (Jensen & Richert, 2005). When reflecting on ethical aspects of practice, practitioners must consider their own values and how those values might influence their work. A value is a belief or an ideal to which an individual is committed (Kanny, 1993). Values clarification is commonly used to aid providers in reflection. Clarifying values and opinions allows practitioners to see elements of a situation that they did not see before, allowing for better appreciation of the complexity of decisions. For a values clarification exercise see Exercise 28.A on the Willard & Spackman Website.

Another form of reflection is mindfulness. Mindful practice entails metaprocessing—thinking about thinking or feeling about feelings. Mindful practice enables practitioners to listen more attentively to clients' distresses, recognize their own errors, refine their technical skills, make evidence-based decisions, and recognize the values necessary to act with compassion, competence, presence, and insight (Epstein, 1999).

Use of narratives, both written and oral, is another form of reflection. Telling stories allows therapists to reason through the moral features of a situation and develop a judgment about what ought to be done (Mattingly, 1998).

Guided narrative review with a mentor is an effective way to infuse ethical reasoning into clinical practice.

Identifying Different Types of Ethical Problems

When reflecting on an ethical issue, it is important to distinguish among the different types of ethical problems that occur in clinical practice. An ethical problem is a situation that is believed to have negative implications regarding cherished moral values and duties *and* that will pose an extremely difficult choice to an individual or group of individuals (Purtilo, 2005). It may be manifested by an emotional reaction such as discomfort, anxiety, or anger. An ethical issue is often captured when the clinician says, "This just doesn't feel right." This "not right" feeling is an emotional response that serves as a trigger to initiate ethical reflection. These feelings are often moral challenges and must be worked out beyond gut feelings to reasoned alternatives and actions.

Ethical distress is a type of problem that occurs when clinicians know the right thing to do but cannot achieve it because of external barriers or uncertainty about the outcome (Purtilo, 2005). Often, multiple stakeholders are involved in the care of the client (e.g., the primary care physician, consulting specialists, rehabilitation practitioners, the organizational administrator, the private insurer, and the family). Ethical distress occurs when stakeholders hold different opinions regarding the goals of care, leaving practitioners with no clear course of action. While conflict may arise in the care of patients, the paramount goal should always be patient's welfare. Ethical distress must be worked through so that this goal can be achieved.

An ethical dilemma is slightly different from an ethical distress. A dilemma is a situation that is marked by conflict between ethical beliefs and involves choice between alternatives that appear to be equally morally unacceptable (Purtilo, 2005). An ethical dilemma exists when the individual has obligations to do both X and Y but cannot do both (Horner, 2003). In a true dilemma, there is a strong persuasive argument both for and against a course of action, posing a moral conflict for the individual.

ETHICAL THEORIES AND PRINCIPLES THAT APPLY TO CLINICAL PRACTICE

Theories provide support for clinical decision making. Ethical theories and principles provide us with language for diagnosing, communicating, and problem solving ethical questions in clinical practice. Ethical theories are well-developed, systematic frameworks of rules and principles (R. J. Nash, 2002). They provide reasons and ideals for ethical standards. Many ethical approaches and theories serve as a reference point for guiding clinical decision making. The most commonly used ethical approaches in health care ethics are principle-based approaches, virtue- and character-based ethics, utilitarianism, and deontology.

Principle-Based Approach

A principle-based approach to ethics relies on ordinary shared moral beliefs as theoretical content. Principles are duties, rights, or other moral guidelines that provide a logical approach to analyzing ethical issues for a given situation. In case analysis, principles are identified, applied, and compared to weigh one principle against another in deciding a course of action. The following principles are commonly used in clinical ethics:

◆ Autonomy. Autonomy is the ability to act independently on one's own decisions (Beauchamp & Childress, 2001). Because autonomy is so highly valued in Western society and medicine, it is often regarded as the most important element in health care decision making (Pellegrino, Siegler, & Singer, 1991).
◆ Beneficence. Beneficence refers to actions done on or for the benefit of others.
◆ Nonmaleficence. Nonmaleficence is the duty not to harm others.
◆ Fidelity. Fidelity means being faithful to both implicit and explicit promises or commitments.
◆ Justice. Justice refers to equal treatment. It deals with the proper distribution of benefits, burdens, and resources. Procedural justice is often used to reflect impartial decision-making procedures. Distributive justice refers to the equitable allocation of societal resources such as health care (Horner, 2003).
◆ Veracity. Veracity refers to telling the truth.
◆ Paternalism or parentalism. Paternalism or parentalism occurs when an individual assumes to know best and makes decisions for the client (rather than with a client). Paternalism can limit clients' access to information and violates their autonomy.

Virtue- and Character-Based Ethics

Virtues are dispositions of character and conduct that motivate and enable clinicians to provide good care (Fletcher, Miller, & Spencer, 1997). Virtue ethics, derived from Aristotle and Thomas Aquinas, focuses on moral agents and their good character. Using this approach, moral goodness is achieved when behaviors are chosen for the sake of virtue (caring and kindness) rather than obligation.

Utilitarianism

Utilitarianism derived from the work of Jeremy Bentham and John Stuart Mill is concerned with actions that maximize good consequences and minimize bad consequences. From this perspective, morally right acts produce the best overall results; that is, the ends justify the means. Utilitarianism is often used in public policy development. A common criticism of utilitarianism is that it deemphasizes

relationships to maximize outcomes for as many people as possible.

Deontology

Deontology is a duty-based moral theory that is based primarily on the work of Immanuel Kant. In this theory, moral rules are universal and never to be broken; consequently, doing one's duty is considered primary, regardless of the consequences. For example, truthfulness is an unconditional Kantian duty. A practitioner would never protect a client from the truth even if the truth would harm the client in some way. From a Kantian perspective, respect for people is a moral imperative; therefore, withholding the truth disrespects clients' right to know. A common criticism of deontology is that it overlooks the potential for conflicting obligations, overemphasizes rules, and underemphasizes the consequences of action.

ETHICAL RESOURCES AND JURISDICTION

Resources

Practitioners who face ethical issues must be knowledgeable about the resources that exist to support them in this dimension of their clinical reasoning. Resources are crucial for sharing the uncertainties related to ethical issues that practitioners encounter at all levels of practice.

Ethics Committees

Ethics committees support practitioners who need assistance in reasoning about ethical dimensions of care. The three primary roles of ethics committees are consultation, education, and policy review and development. The courts, the President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research, and accrediting agencies such as the Joint Commission on the Accreditation of Hospital Organizations recommend consultation with ethics committees (Aulisio, Arnold, & Younger, 2000). Ethics committees provide an environment for safe and open discussion of basic moral questions, ease the feelings of staff, provide knowledgeable resources, and empower clinicians to make morally justified decisions.

Effective ethics committees are interdisciplinary and have strong institutional support. They analyze cases from many different perspectives to ensure the best outcome for clients. Occupational therapy practitioners who are either interested novices or experts in ethics should serve as members of ethics committees because they can bring broad perspectives to ethics discussions, are resources for topics related to values clarification and quality of life, and are skilled in group facilitation. Practitioners in settings without ethics committees should use their mentors, managers, administrative supports, and professional organizations for assistance with ethical issues. Other organizational resources, such as the office of patient care advocacy (also known as the ombudsman), office of social work, chaplaincy service, and office of legal counsel, can also provide guidance with ethical issues.

Institutional Review Boards

Increased impetus for research and attention to evidence-based practice have resulted in an increase in the number of occupational therapy practitioners involved in clinical research. All clinicians who are involved in research activity have a moral obligation to familiarize themselves with the rules, regulations, and ethical obligations of conducting responsible research. There are many ethical considerations in research (e.g., data integrity, conflict of interest, authorship), but the most compelling pertains to human subjects as research participants.

To ensure an objective review of ethical issues related to human subject research, any institution that receives federal funding is required to have an Institutional Review Board (IRB). An IRB is a panel of diverse individuals, including organization staff and at least one community member, who are responsible for reviewing all research proposals and grants to ensure that adequate protections for research participants are in place. These protections include informed consent, research design and methodology, recruitment, the balance of risks and benefits, and confidentiality. The three fundamental principles that guide the ethical conduct of research involving human participants are respect for persons (autonomy), beneficence, and justice (National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, 1979). Occupational therapy practitioners should refer to their organization's specific policies and regulations regarding oversight and training in ethical conduct in research.

Codes of Ethics

Codes of ethics embody professional ethics (Banks, 2004). They are written documents produced by professional associations, organizations or regulatory bodies that state the commitment to a service ideal or core purpose. Ethical codes ensure public trust and safeguard the reputation of a profession. Codes of ethics are often aspirational, educational, and regulatory in nature (Banks, 2004). The values articulated in the ethical code serve to guide professional practice.

The AOTA's Occupational Therapy Code of Ethics (AOTA, 2005) serves as a guide to professional conduct. It is supported by the Guidelines to the Occupational Therapy Code of Ethics (AOTA, 2006) and the Core Values and Attitudes of Occupational Therapy Practice (AOTA, 1993). Together, these three documents, known as the Ethics Standards, serve as resources to all occupational therapy practitioners encouraging them to attain the

highest level of professional behavior. These documents reflect the values and beliefs of the profession and provide clarification and support when an ethical issue arises. Additional information about the code and related documents and the AOTA Ethics Commission can be found at www.aota.org.

Regulatory Agencies

Three types of organizations provide oversight for occupational therapy practice: the AOTA, the National Board of Certification in Occupational Therapy, and state regulatory boards. Each has distinct concerns, sanctions, and jurisdiction, but one commonality is their concern for ethical practice.

The American Occupational Therapy Association

The AOTA, the professional association for occupational therapy, is the primary vehicle for influencing, promoting, and developing the profession's services to society (Doherty, Peterson, and Braveman 2006). The AOTA develops standards of practice for all occupational therapy practitioners. These standards are an essential resource for clinicians, students, educators, and researchers. As health care professionals, occupational therapy practitioners have an obligation to understand, respect, and demonstrate the values and ethics of the profession (Slater, 2006).

Within AOTA, the Ethics Commission reviews the AOTA Occupational Therapy Code of Ethics every five years. Its primary responsibility is to recommend the ethics standards for the profession. It also educates members and consumers regarding ethics standards. Ethics Commission members and staff of the AOTA Ethics Program are resources for students, clinicians, educators, and consumers. They provide assistance with the interpretation of relevant ethical principles via advisory opinions, consultation, articles, and presentations. Finally, the Ethics Commission is responsible for the process of developing and implementing the enforcement procedures for the code. Disciplinary actions apply to members of AOTA and include reprimand, censure, probation, suspension of membership, and permanent revocation of membership.

National Board for Certification of Occupational Therapy

The National Board for Certification in Occupational Therapy (NBCOT) is a credentialing agency that provides certification for the occupational therapy profession (NCBOT, 2006). Its mission is to serve the public interest by assuring the competency of all certified occupational therapy practitioners. NBCOT establishes minimum standards for certification to enter practice and ongoing recertification standards, including continuing competency through professional development. The NBCOT Certifi-

cant Code of Conduct outlines professional responsibilities for certified occupational therapy practitioners. As in many organizational codes of conduct, the NBCOT Certificant Code of Conduct includes ethics-related principles such as fairness, honesty, truthfulness, and technical competence. Violation of this code of conduct is grounds for sanction, which may entail reprimand, probation, or suspension or revocation of certification. Suspension or revocation of certification prohibits sanctioned individuals from practicing occupational therapy.

The NBCOT Qualifications and Compliance Review Committee oversees certification violation issues such as breaches of ethics and unprofessional practice. NBCOT notifies state regulatory boards and the public of any complaints it receives and the disciplinary action it takes in response to these complaints. Additional information about NBCOT and the NBCOT Certificant Code of Conduct can be found at www.nbcot.org.

State Regulatory Boards

State regulatory or licensing boards (SRBs) safeguard and promote the public welfare by ensuring that qualifications and standards for professional practice are properly evaluated, applied, and enforced (Doherty, Peterson, & Braveman, 2006). Occupational therapy is regulated in all 50 states and in three U.S. territories. The level of regulation varies; therefore, all occupational therapy practitioners must be aware of the specific provisions and statutes for the state in which they work. Most states use professional licensure to regulate practice, but several have certification, registration, or simply trademark requirements. Licensure is a means of defining a lawful scope of practice. It ensures patient protections and legally articulates the domain of practice for the profession. Licensure also prevents nonqualified individuals from practicing occupational therapy or using the title "occupational therapist" or "occupational therapy assistant." Many states include codes of ethics or codes of ethical conduct) statements in their licensure law or regulations. SRBs have the authority by state law to discipline occupational therapy clinicians who violate regulations, including the state's code of ethics. Practitioners have the responsibility to understand the regulations under which they work and the procedure for processing a complaint.

THE ETHICAL DECISION-MAKING PROCESS

The ethical decision-making process, like the clinical reasoning process, aids in reasoning through a problem in a structured and systematic way. This process provides a way for practitioners to give due consideration to issues, reflect on them, formulate possible alternatives, and make thoughtful choices. Common aspects of ethical

decision-making models are the need for the clinician to do the following:

1. Identify the ethical question
2. Gather the relevant data
3. Formulate a moral diagnosis
4. Problem-solve practical alternatives and decide on an alternative for action
5. Act on the choice and evaluate the results (Bailey & Schwartzberg, 2003; Gervais, 2005; Hansen & Kyler-Hutchison, 1989; Miller, Fletcher, & Fins, 1995; Purtilo, 2005; Scanlon & Glover, 1995).

CASE STUDY: *Dual Obligations and Difficult Conversations: Ethical Issues in Confidentiality and Refusal of Services*

Maura is an occupational therapist working for an early intervention (EI) program. She received a referral on a 2 ½ year old girl named Jen Stone who was recently discharged from the hospital. Jen is the youngest of five children, and the reason for her referral to EI was a recent hospital admission following a home accident. Jen was injured when the Stones were moving. During the move, they removed a door from its hinges to move several large pieces of furniture. The door fell on Jen, resulting in head trauma. Maura's initial evaluation noted that Jen was profoundly delayed in all developmental milestones. Her vocabulary was limited to about 10 words, and she demonstrated a mild left hand weakness and significant delays in fine motor skills. Jen rarely smiled and demonstrated significant stranger anxiety during the evaluation. Ms. Stone reported that all her children were "slow talkers." Ms. Stone thinks that Jen needs medication because of the way she hit her head. In subsequent conversation with Ms. Stone, Maura realized that Ms. Stone was talking about phenobarbital, an anticonvulsant medication that is prescribed to prevent seizures and not designed to foster development. Maura explained the purpose of the medicine and that Jen needs extensive therapy to assist with her neurological recovery. Ms. Stone told Maura that everyone in the hospital wanted Jen to go to a rehabilitation facility but that she really wanted to take Jen home. Maura concluded that Ms. Stone had a poor understanding of typical child development and how this head injury would affect Jen.

Maura left the Stones troubled by the case and with serious questions about Jen and her family. In her monthly meeting with the EI team, Maura brought up her concerns. Shoshona, the caseworker assigned to Jen's case, reported that "this is a high-risk family" and that other siblings had been admitted to the hospital in the past only to be taken home against medical advice. After that meeting, Maura and some of her coworkers went for a quick cup of coffee. As Maura waited in the line at the coffee shop, Shoshona said, "Stick with that Stone case. Make sure you do whatever you need to stay involved. Remember this is a high-risk family." Maura was shocked at this breach of confidentiality and said, "Remember, we are not at the office anymore."

The following week when Maura went to see Jen, Ms. Stone would not let her in, saying that her husband had overheard some people talking about them in a coffee shop. Mr. Stone had told his wife, "If you let *them* in the house again, *you* will regret it." Maura quickly apologized and left, embarrassed, upset, and concerned about Jen and her family.

This case highlights how in clinical ethics, a client's story often begins in one setting and continues to unfold in another. It also highlights the imperative nature of facts in complex ethical decision making. To ensure a professional and caring response to this situation Maura must carefully analyze the ethical issues. The ethical decision-making process serves to help guide her thinking and actions. The following sections describe that process.

Identify the Ethical Question

The first step in addressing an ethical issue is to determine that the problem has an ethical dimension separate from other dimensions (clinical, legal, and political). The occupational therapy practitioner must identify and reflect on the ethical questions that have emerged in the case. This often begins with the question "What should I do?" In the case of Jen and Maura, some of the ethical questions are as follows:

◆ Should Maura persist in seeking to follow up with Ms. Stone and Jen? If she does, will she be doing more harm than good?
◆ Should the Stones have the right to refuse services for their daughter?
◆ Should the facility discuss the breach in confidentiality with the Stones? With their overseeing agencies? Could the facility regain the trust of the family despite this breach?
◆ Should Maura advocate for the organization or for Jen and the Stones? How can she balance her dual obligations to the Stone family and the organization?

In clinical practice, ethical questions often occur alongside clinical and legal questions. Our emphasis here is on the ethical analysis of this case. However, practitioners must also be aware of the legal and clinical dimensions to effectively analyze complex cases. One of the ethical questions identified above is "*Should* the Stones have the right to

refuse services for their daughter?" This is different from the legal question "*Do* the Stones have the right (legally) to refuse services for their daughter?" One of the clinical questions in this case is "What would be the impact of denied therapeutic intervention on Jen's development?" Another is "What is the evidence to support timing of intervention following head injury?" The practitioner must consider these various dimensions and reflect on the contribution of each to the overall critical reasoning process, the goal being to achieve the best outcome for the client.

Gather the Relevant Data

The next step in ethical analysis is to gather the relevant data identifying the known facts and beliefs about the case. It is important to distinguish between the two. Facts are needed to make judicious decisions. Facts regarding medical information and factors such as family context, client preferences, social and cultural issues, institutional factors, and provider considerations should be confirmed for accuracy. Additional information should be sought if needed.

Some of the facts regarding the current problem are as follows:

◆ Jen presents with developmental skills that are well below the norm for her chronological age.
◆ The Stones took Jen home against the advice of hospital staff members, who recommended transferring Jen to an inpatient rehabilitation facility.
◆ Ms. Stone has a low education level.
◆ Maura has been denied access to the home.
◆ The caseworker broke confidentiality and violated client privilege when talking about the case at the coffee shop.

Some of the beliefs are as follows:

◆ There might be neglect or abuse in the home.
◆ Jen's parents are not acting in her best interests by refusing inpatient rehabilitation and early intervention.
◆ Jen's baseline status was one of significant developmental delay.
◆ Jen would have made more progress in a rehabilitation facility than at home.
◆ The Stones believe that the caseworker's breach of confidence was intentional. (In most cases, breaches in confidentiality are not malicious in nature but rather are either unintentional disclosures with the goal of bringing about a good result or the result of carelessness.)

Formulate a Moral Diagnosis

Once the information has been gathered, a moral diagnosis must be formulated by identifying the type of ethical problem and the principles that apply to the case. If there is more than one problem, they should be ranked in order of importance.

Having considered the ethical questions in the case of Jen, Maura must decide whether the ethical problem is distress or dilemma. As is common in clinical practice, many cases pose distress; however, Jen's case is a true dilemma because Maura is faced with two courses of action, both of which appear to be unacceptable. If she returns, Jen and Ms. Stone might be harmed by Mr. Stone. If she does not return, Jen's development is at risk. Maura is having difficulty deciding what to do that will both honor the principles of beneficence (doing good for Jen) and nonmaleficence (not causing harm to Jen and Ms. Stone). Maura knows that Shoshona's breach of confidentiality violated the family's trust (fidelity) and that she must take steps at her facility to ensure that the confidentiality of others is not violated in this way again (justice). Maura is also in a position in which she might need to balance organizational and professional responsibilities.

There are many stakeholders in this case, and there are multiple issues of power between and among Mr. and Ms. Stone, Maura, Shoshona, and the EI agency.

Problem-Solve Practical Alternatives and Decide on a Course of Action

Now that Maura has delineated the facts and beliefs about the problem, she must begin to identify practical alternatives and decide what do. Maura must ask herself, "What is the good or right thing to do?" She would be wise to seek out ethics resources in her facility and to ask her mentors for guidance in this ethical analysis. She might consult with various stakeholders, such as the social work office, the EI service director, Jen's pediatrician, and the team, to identify strategies to engage the family and regain their trust. She could also meet with the agency's ethics committee or read resources such as the AOTA Occupational Therapy Code of Ethics. These resources will help to guide Maura's reflection and subsequent actions. Generating a list of alternatives enables evaluation of the positive and negative consequences. Once the alternatives have been identified, ethical theory should be applied to support and justify the proposed action.

Maura brainstormed a list of possible alternatives:

◆ Approach Ms. Stone one last time to clarify the facts and ensure that she is making an informed refusal of services
◆ Apologize for the breach in confidentiality in an attempt to move forward
◆ Tell the family about the steps the agency has taken to ensure that this breach in confidentiality does not happen again

Continued

CASE STUDY: *Dual Obligations and Difficult Conversations: Ethical Issues in Confidentiality and Refusal of Services*   *Continued*

- ◆ Offer an alternative practitioner to work with Jen
- ◆ Offer an alternative agency or setting to provide services

   Maura will need to reason through the alternatives, apply ethical theory to support her actions, and come to a judgment on the best approach. Maura and her employer might also need to consult with agency's legal counsel, since the confidentiality breach represents a HIPAA (Health Insurance Portability and Accountability Act) violation. Having virtue, sensitivity to ethical issues, and a process for analyzing ethical questions are important elements in ethical decision making. Maura weighs all of the alternatives and, after conversations with multiple resources, decides to reapproach Ms. Stone ensure that she is making an informed refusal and, if so, to offer her alternative agencies to service Jen and social service resources, should she wish to pursue them.

Act on That Choice and Evaluate the Results

Now that Maura has decided on the course of action, she must act on the decision, bridging the gap between knowing what she ought to do and actually doing it. This is where the Aristotelian notion of practical wisdom and moral argument join together with clinical judgment for action. Often, this is the most difficult step because it requires calling on moral courage to take positions that are unpopular or contrary to the interest of others (Aulisio et al., 2000). Moral courage is a skill. It involves facing and overcoming fear to uphold an ultimate good.

   Maura will need courage to talk with Ms. Stone. She must uphold the virtue of humility and acknowledge the error in the EI system. Maura must also have the fortitude and skill to engage the family in regaining trust so that Jen will have access to therapy. She will need to be attentive to the interests and emotions of the family and remember the ultimate goal, which is to get Jen the therapy she needs. Maura must justify her action with moral reasons. If the social worker and Maura gather evidence of abuse or neglect in the home, they will need to familiarize them-

selves with EI agency and state policies on mandated reporting. Maura will need to be creative in coming up with alternatives to this complex situation so that the ultimate goal of caring for Jen is achieved. She might also have to make sacrifices for Jen's benefit. This could include withdrawing from the case and turning it over to a different EI agency so that Jen will receive intervention.

   Finally, Maura must evaluate the results of her action. Evaluation includes both current and retrospective analysis. Seeking the input of knowledgeable colleagues and even ethics committee members can be helpful in evaluating the outcome of the actions taken. This analysis can guide future action by either avoiding or preventing a similar situation or knowing how to act should a similar situation arise in the future. Questions Maura might ask are as follows:

- ◆ What have I learned from this case to help improve future patient care?
- ◆ What have I learned that will contribute to my own moral life and to my virtues as a practitioner?
- ◆ How has this case affected me as a care provider?
- ◆ What additional knowledge do I need to be more effective in handling future ethical dilemmas?

   Evaluation of the decision-making process in cases such as this one has the potential to change clinical practice, policies, education, or service delivery systems. Evaluation provides the opportunity for personal and professional refection that can lead to further professional development and greater confidence to respond to future ethical dilemmas. Maura could also work with her colleagues and agency to make changes in policies (such as confidentiality and disclosure) and staff education so that a similar breach of confidentiality does not occur in the future. Maura should also consider how those she consulted with contributed to the case and should critique her own decision-making process to improve her future practice.

DIFFICULT CONVERSATIONS

The case of Maura and Jen highlights how practitioners must engage in difficult conversations. Some of these are with clients, some with families, and some with colleagues. While these conversations may be uncomfortable and awkward, through development of effective listening and communication strategies, practitioners can become more skillful and confident in meeting this challenge.

   Occupational therapy practitioners who are empathetic are better prepared for difficult conversations. The discus-

sion of empathy is relevant in ethical decision making as it can help practitioners appreciate the experience of those who seek their care. However difficult these discussions might be, clients also have difficult choices. Developing the ability to evaluate a client or family's behavior requires practitioners to appreciate and accept a different perspective and different choices (Cohen, 2004). This is the first step in demonstrating moral sensitivity.

   Open communication and empathy are key components to the delivery of compassionate care. The following are suggestions for effective communication:

1. **Be present.** Always respect others. Try to minimize interruptions and ensure that the environment is as free of distractions as possible. Choose an appropriate communication style for the situation. Establish rapport by making good eye contact, sitting close to the person, and/or touching the person as appropriate to communicate support.

2. **Use open-ended communication and listen quietly.** We often say too much, which does not allow time for the other person to speak. Phrases such as "go on" can encourage the person to examine issues at a deeper level (Cameron, 2004).

3. **Remain focused on the person and the goals of intervention.** Are the goals appropriate and achievable? Do they maximize benefit and minimize burden? If the conversation begins to stray off the topic, bring it back by stating, "While I appreciate you sharing that interesting information, it diverts us from our focus today, which is on. . . ."

4. **Be contrite and humble.** If you do not know the answer to a question, say so and assure the person that you will find the answer. Then find the answer and follow up with the person. Share your uncertainty about the case or prognosis.

5. **Legitimize the losses that the person is experiencing.** It is important to acknowledge the person's experience. Many clients are not prepared to cope with their newly diagnosed condition. They did not expect ever to be in a compromised state, and their family might not be able to cope with the personal or financial implications of this change. Denial, depression, and anger are common responses to disease and disability. Practitioners need to acknowledge these emotions openly by stating, "What I am hearing you say is that you are angry that you can no longer cook" or "Let me see if I can summarize what your daughter is trying to say. . . . . Is that correct?"

6. **If you are having difficulty with an issue, think how the problem might be experienced from the client's perspective** (L. Nash, 1981). By listening more openly to the other side of the argument, one can appreciate it for what it is (Cohen, 2004).

7. **Acknowledge 'the elephant in the room'** (Quill, 2000). Questions surrounding quality-of-life and end-of-life issues can be especially complex. Occupational therapy practitioners who have established relationships with their clients are obligated to fully inform clients of the likelihood of the success or failure of therapeutic interventions. It is important to engage clients in shared decision making. Practitioners should keep questions straightforward, listen carefully to answers, and follow the person's lead by asking focused follow-up questions using the person's own words. Asking questions such as "What are your most important hopes?" and "What are your biggest fears?" can assist both practitioner and client in setting appropriate goals for care (Quill, 2000).

8. **Pay attention to the words you use and how you use them.** Be aware of your tone, facial expressions, and body language. Use calm and composed language (Weeks, 2001). If the content of your message is clear, the listener can better process the information.

CONCLUSION

Ethical issues are ever present in professional practice and will continue to challenge occupational therapy practitioners as the fields of medicine, technology, and health care delivery evolve. Occupational therapists must recognize, critically reason, act, and reflect on ethical issues that arise in their professional roles. Occupational therapy practitioners who are reflective and knowledgeable in ethical decision-making processes are best prepared to successfully address ethical aspects of practice. Ethical behavior is the responsibility of all occupational therapy professionals.

> You have chosen a career path that will require complex (and at times perplexing) judgments about morality regarding patient care, health policy and other aspects of professional life. Many such judgments will have significance in terms of your own moral life, that of your profession, and that of society. But the path is not one you must forge anew every step of the way. (Purtilo, 2000)

Client-Centered Collaboration

29

SUSAN AYRES ROSA

Learning Objectives

After reading this chapter, you will be able to:

1. Discuss the terms *collaboration, client-centered care,* and *autonomous moral agency* in the context of health care.
2. Describe the benefits to clients and practitioners of client-centered collaboration.
3. Identify environmental and personal factors that can pose challenges to using client-centered principles in occupational therapy practice.
4. Discuss the importance of client advocacy, communication skills, and negotiating differences with clients over therapy goals and expectations to client-centered practice.

INTRODUCTION

Prominent among the values reflected in the official documents of the American Occupational Therapy Association (AOTA) is an appreciation of and respect for the uniqueness of individual clients and each client's right to exercise choice and self-direction (AOTA, 1998, 2002, 2005). The AOTA Code of Ethics (AOTA, 2005) specifically mandates that practitioners respect their clients' rights to influence decisions that affect them. One way in which practitioners act in accordance with these ideals and ethical mandates is by encouraging clients to participate in all phases of the therapeutic process, including problem identification, goal setting, intervention planning, and evaluating outcomes. Working together with clients in this way is at the heart of collaborative models of care and client-centered practice in occupational therapy (Corcoran, 1993; Law, 1998).

In this chapter, we examine the terms *collaboration* and *client-centered* and review the research evidence on the outcomes of client-centered practices. We also explore some of the challenges facing practitioners that may help to explain why being client-centered remains elusive for occupational therapists.

COLLABORATION IN HEALTH CARE

To collaborate with clients in health care means working with them to find common ground regarding health-related problems and what to do about them. Collaboration involves a dynamic process of information sharing and

negotiation in which both clients and practitioners are active partners. Clients must be able and willing to express their concerns. Practitioners must strive to understand those concerns while also sharing their expertise and technical knowledge.

Collaborative models of care, such as client-centered practice, are grounded in the conviction that clients are capable of acting as autonomous moral agents on their own behalf (Bartholome, 1992). This is the notion that clients not only have the right and the capacity to contribute to the decisions that affect them, but also are the experts on their own illness-related experiences. Because of the personal knowledge that clients have of their own situation, they are likely to know better than health care professionals can what will work for them. As our profession struggles to glean knowledge from relatively scant research evidence to guide decisions about best practices, practitioners must strive to seek out and honor the personal knowledge that clients bring to the therapy encounter; it may be the best and most relevant evidence available to them.

BEING CLIENT-CENTERED

In occupational therapy, the ideal of collaboration is incorporated in the concept of client-centered practice (Law, Baptiste, & Mills, 1995). The term *client-centered practice* dates back to the late 1930s and the writings of the psychologist Carl Rogers, who championed an approach to counseling that focused on the concerns that clients themselves identified (Law & Mills, 1998). The foundation of Rogers's approach is a respect for the unique cultural values of clients and a belief that clients both desire and have the capacity to take an active role in directing their own care. Rogers ardently believed that clients know best their own needs and experiences.

The following seven concepts are common to all occupational therapy models of client-centered practice:

1. Respect for clients and their families and the choices they make
2. Recognition that clients and families have the ultimate responsibility for decisions about daily occupational and occupational therapy services
3. Provision of information, physical comfort, and emotional support with an emphasis on person-centered communication
4. Facilitation of client participation in all aspects of occupational therapy service
5. Delivery of flexible, individualized occupational therapy services
6. Facilitation of the capacity of clients to solve their occupational performance issues
7. Recognition of and focus on the person-environment-occupation relationship (Law & Mills, 1998)

This list clearly reflects a respect for clients as autonomous moral agents and the principles that Rogers espoused.

RESEARCH EVIDENCE

While research evidence is scant that addresses the effectiveness of a specifically client-centered approach in occupational therapy, an emerging body of research findings suggests multiple benefits to be derived from incorporating client-centered principles. Moreover, this evidence suggests that both clients and practitioners benefit.

The benefits that have been reported for occupational therapy clients from using a client-centered approach include improved functional performance in areas of interest to them, resumption of life roles, decreased pain, improved safety and physical health, and increased levels of satisfaction with therapy and the outcomes of intervention (Case-Smith, 2003; Horowitz, 2002; Van Leit & Crowe, 2002). A greater awareness on the part of clients of their therapy goals and increased adherence to intervention recommendations have also been associated with treatment approaches that incorporate client-centered principles (Case-Smith, 2003; Law, Baptiste, & Mills, 1995; Wressle, Eeg-Olofsson, Marcusson, & Henriksson, 2002).

A number of studies have examined client perspectives on occupational therapy generally (McKinnon, 2000; Palmadottir, 2003) and client-centered practices specifically (Corring & Cook, 1999; Darragh, Sample, & Krieger, 2001; Sumsion, 2005). These, like the personal testimonial of Mary Feldhaus-Weber printed in Chapter 11, teach us how important it is to clients and how empowering it can be for them when practitioners are willing to listen carefully to clients' concerns, honor their abilities, and trust their knowledge about what is best for themselves.

Research has also shown that working in a client-centered way can have important consequences for practitioners. Occupational practitioners who feel that they have helped clients in ways that are meaningful to the clients report a strong sense of connection with those clients and a sense of joining with them in mutually supportive partnerships. These types of experiences nourish and sustain practitioners and motivate and inspire them in their work (Rosa & Hasselkus, 1996). Interestingly, findings from this same research suggest that not being able to work collaboratively with clients can be associated with a drain on practitioners' emotional resources and feelings of guilt, rejection, and even failure.

THE CHALLENGES OF CLIENT-CENTERED COLLABORATION

In view of the ethical mandate to be client-centered and the documented benefits to clients and practitioners alike, it is important to point out that being client-centered has been troublingly elusive for occupational therapy practitioners. Studies have shown, for example, that practitioners do not always attempt to collaborate with clients; do less than they could to ensure clients' participation in problem identifica-

tion, goal setting, and intervention planning; and employ communication styles that inhibit client participation and information sharing (Allison & Strong, 1994; Clark, Corcoran, & Gitlin, 1995; Hasselkus & Dickie, 1990, 1994; Helm & Dickerson, 1995; Levine & Gitlin, 1993; Neistadt, 1995; Northen, Rust, Nelson, & Watts, 1995; Rosa & Hasselkus, 1996). The reasons for these behaviors can be complex. Challenges include institutional barriers associated with therapy settings and personal factors related to both therapists and clients.

Contextual Influences on Client-Centered Collaboration

Occupational therapy practitioners have traditionally worked in hospitals and other medical settings where the medical or expert model tends to be the dominant model of service delivery. Historically, the medical model has included the beliefs that power and control over medical decisions rightly reside primarily with professionals because of their superior knowledge and authority. In this model, clients have a corresponding duty to comply with the expert advice that medical professionals offer. The expert model continues to exert a strong influence in some settings (Fearing & Ferguson-Pare, 2000; Kyler, 2005; Lawlor & Mattingly, 1998; Wilkins, Pollock, Rochon, & Law, 2001). Being client-centered in such contexts challenges practitioners to advocate for clients whose voices might not otherwise be heard and to provide leadership in promoting change within the institution (Fearing & Ferguson-Pare, 2000).

In rehabilitation settings, the goals and expectations of therapy emphasize independence, hard work, and having clients do as much as possible for themselves. Because these goals are so universal in rehabilitation and so strongly advocated, at times without a determination of whether they are in line with what clients want for themselves, some have suggested that they constitute a rehabilitation ideology (Hasselkus, Dickie, & Gregory, 1997; Lawlor & Mattingly, 1998). Indeed, occupational therapy practitioners working in rehabilitation settings have described ways in which they persisted in pushing such a rehabilitation agenda even in the face of strong resistance from clients (Rosa and Hasselkus, 2005). The challenge for practitioners working in rehabilitation is to understand clients' values and concerns and reflect on the extent to which these may differ from any taken-for-granted goals and expectations that might be imposed on clients as the result of a rehabilitation ideology.

Personal Influences on Client-Centered Collaboration

In addition to institutional barriers, personal factors associated with both clients and therapists can present barriers to the process of information sharing and negotiation necessary to practicing in a collaborative, client-centered way. If clients are either unable or unwilling to express themselves, voice their concerns, or otherwise take an active part in the process or if practitioners do not listen carefully for clients' concerns or do not have the skills or patience necessary to work around the many difficulties that can arise, the process can break down.

Among the reasons why clients might be unable or unwilling to be effective partners with therapists are language differences, aphasia, hearing loss and other barriers to basic communication, physical or cognitive deficits, psychological issues, and cultural differences. Clients might simply be too sick or too tired to identify goals or make decisions about their care. Cognitive limitations, level of education, and mental illness can interfere with a client's ability to think clearly or comprehend issues involved. Distrust of others, anger, anxiety, depression, and disorganized and delusional thinking can limit the ability to engage in effective partnerships. Clients might have cultural beliefs that cause them to be uncomfortable making decisions about their own care. Practitioners are called on to overcome the barriers that are present to the extent possible in an effort to understand clients as fully as they can and share the power and responsibility of decision making (Precin, 2002; Sumsion, 1999).

The above examples make clear that collaborative, client-centered care can require high-level communication and sophisticated personal interaction skills. Thomson (2000) has suggested, in fact, that clients who present some of the kinds of difficulties referred to above should perhaps be considered "specialist cases" (p. 11) because of the level of advanced skill Thomson believes is necessary to collaborate with them effectively.

In addition to skill, practitioners must be open to exploring differences regarding therapy goals and expectations with clients whose goals, culture, and life experiences might be very different from their own (Sumsion & Smyth, 2000). The range of individual differences within cultures and the potential for vastly different world views between cultures can offer new challenges with each patient. When differences are present, effective communication demands an openness to exploring these differences with clients in addition to skill and patience in negotiating them.

Findings from a recent study reveal that occupational therapists do not always display this kind of openness to exploring differences with clients (Rosa & Hasselkus, 2005). Rather, agreement on therapy goals and expectations seemed to be based on compatibility with clients rather than on negotiating differences with them. The occupational therapists who participated in the study collaborated readily with clients with whom they felt considerable rapport, clients who were "on the same wavelength" when it came to therapy goals and expectations and with whom they felt a strong connection. Conversely, therapists found themselves at odds with clients with whom this was not the case and experienced conflict and

tension surrounding therapy goals and expectations when working with these clients.

Social psychologists tell us that it is natural for each of us to be more open to some people than others. For example, we are more likely to help someone to whom we are attracted, we are attracted to people with whom we feel some measure of compatibility, and we communicate most readily with those with whom we have positive interactions (Schroeder, Penner, Dovidio, & Piliavin, 1995). These behaviors are a spontaneous expression of our feelings toward those to whom we feel attracted and with whom we feel some connection. Correspondingly, it might be only natural for us to be less open to helping clients who are angry, demanding, or unpleasant or who present us with other tough behavioral or communication challenges. It is easy to understand, then, that it might be harder for us to find the motivation to understand clients like these.

In professional-client relationships, the professional has the responsibility to try to understand all clients, even those with whom they feel they have little or nothing in common, who are unpleasant, or with whom they feel little or no attraction or rapport. If occupational therapy practitioners are to accept the responsibility to face these challenges, to bridge differences, and to resolve conflicts, they, like all professionals, must get beyond what simply comes naturally to them. This is the point that Montgomery (1993), a nurse scholar and researcher, stresses:

> This natural state of responsiveness and commitment is not adequate by itself to ensure effective caring on a professional level. Clients who have contact with helping professionals expect more than good intentions. Therefore, helping professionals not only must be competent in the skills and science of their profession, but also must possess sophisticated relational and communication abilities to handle a variety of interpersonal and relational challenges and demands. In other words, making a commitment to care is not easy. Caregivers need to develop communication abilities that will allow them to continue to stay involved and continue to be therapeutic in the face of these demands and challenges. (p. 14)

Because of the many challenges that may be present, engaging in the kind of dialogue necessary to achieve effective collaboration and meaningful exchange of information with all clients can be inordinately difficult. The importance of developing strong communication and interpersonal skills cannot be emphasized enough.

CONCLUSION

Occupational therapy practitioners have an ethical responsibility to include clients in discussions regarding their own care and to provide them with the opportunity to share in the decisions that affect them. But as we have seen, multiple factors present a host of difficult challenges to uphold-

ing our profession's ideal of client-centered collaboration. To be successful, occupational therapy practitioners must work against the institutional factors that can negatively influence decision-making processes, commit themselves to developing the requisite communication skills, and strive for the kind of openness to difference with others over values and beliefs that is necessary to overcome gaps in understanding. Only then will occupational therapy professionals be able to nurture greater health and well-being for the clients they so want to help and for themselves.

PROVOCATIVE QUESTIONS

1. Should all clients be considered "autonomous moral agents"? Might there be some individuals who are not capable of serving as their own moral agents?

2. Penny Kyler (2005) has advocated that occupational and physical therapists go beyond a client-centered or family-centered model to a relationship-centered approach, which takes into consideration the individual client and his or her relationships to others and to all of the external environments that may exert influence the therapist-client interaction. These external environments include the social, political, economic, physical, and cultural contexts in which the client-therapist interaction takes place. To what extent do you agree with Kyler? Does the model of client-centered collaboration described here fit with Kyler's notion of a relationship-centered approach?

3. How do you feel about the relative importance of clients' personal knowledge of their illness experiences and the evidence-based, technical knowledge that therapists have? To what extent do you agree that the first may be more important that the second?

Evidence-Based Practice

Using Available Evidence to Inform Practice

LINDA TICKLE-DEGNEN

30

Learning Objectives

After completing this chapter, you will be able to:

1. Describe how research evidence provides central tendency, or generality, information about individuals as well as individual variation among individuals.
2. Describe the clinical tasks for which to use evidence.
3. Name the basic steps of using evidence.
4. Write answerable clinical questions.
5. Identify key terms for searching research literature effectively.
6. Describe how to appraise the clinical relevance and trustworthiness of a research report.
7. Describe qualities of effective communication about evidence.
8. Describe how evidence-based practice can be client-centered.

INTRODUCTION

Imagine that you are going to work with a new client tomorrow. What do you do? How do you decide what this client needs and how you might help the client to achieve occupational goals? You might do what an occupational therapy student, Rebecca Reis (1994), did as she prepared to meet a new client. Rebecca's fieldwork supervisor assigned her to work with Wanda, a middle-aged woman with a Colles' fracture, who up until then had been receiving occupational therapy from the supervisor. Wanda would be not only a new client to Rebecca, but also her first client in a busy, fast-paced outpatient clinic and one with an unfamiliar diagnosis.

In preparation, Rebecca discussed Wanda with her supervisor to receive expert guidance and then looked over Wanda's medical chart to orient herself to the nature of Wanda's medical problem and current interventions. During their initial session together, Rebecca asked Wanda directly how she was managing at home, to understand Wanda's personal experience of daily life activities with this type of fracture, and examined her wrist

to assess directly the nature of Wanda's wrist functioning. Wanda reported minor problems at home, and Rebecca implemented a supervised protocol of modalities and exercises directed at maximizing Wanda's wrist function.

Over five or six sessions, Rebecca found Wanda to be pleasant and courteous but relatively indifferent to questions about how she was managing at home with regard to her wrist. They passed their therapy sessions in light conversation until their very last session together. At that time, Wanda opened up and told her personal details about her life, including sexual abuse as a child and lengthy rehabilitation for her own substance abuse. She talked about how a girlfriend had always told her she should write a book about all that she had experienced and how she had once started to write it all down. Rebecca was "stunned" (Reis, 1994, p. 351) and moved. Rebecca ended the therapy sessions believing the Colles' fracture to be insignificant in the scheme of Wanda's life. Rebecca did not know what to do with the information that Wanda had given her in that last session, although she recognized that the information was quite significant.

We, like Rebecca, cannot know whether or not the information that she learned in that last session could have been used or could have been helpful if known earlier or whether, if known earlier, it would have changed the direction of therapy or its outcome. However, for the purposes of this chapter, I use Rebecca's vivid story (Reis, 1994), as reported to Mattingly and Fleming (1994) for their research study on clinical reasoning, to illuminate how **evidence-based practice** might create a different scenario for working with a client like Wanda. In fact, Rebecca and Wanda worked together before the movement of **evidence-based practice** had taken hold in healthcare (Sackett et al., 2000). Rebecca did everything correctly, given her student role and the standards of occupational therapy and other health care professions in the 1980s and into more recent times. She recognized that she needed information, or evidence, for providing occupational therapy that would ben-

efit Wanda. The forms of evidence that she used to inform her work with Wanda were expert opinion, medical records about tests and interventions conducted with Wanda, information from Wanda herself, and direct observation of Wanda's wrist function.

Because it was not common practice to do so at the time, there is a form of evidence that Rebecca did not seek out or use. She did not use evidence from research studies to inform her practice with Wanda, the type of evidence meant in the term *evidence-based practice.* It is only now, approximately 20 years later, that occupational therapy practitioners are starting to use this type of evidence in their practice, though not yet consistently. This chapter describes how evidence from research studies can be put into practice consistently and in a manner that enriches the contributions of occupational therapy and the outcomes of clients.

CLINICAL REASONING ABOUT HUMAN BEINGS IN RELATION TO RESEARCH EVIDENCE

> Central tendency is an abstraction, variation the reality. . . . I am not a measure of central tendency, either mean or median. I am one single human being with mesothelioma. . . . I must not simply assume that my personal fate will correspond to some measure of central tendency. (Gould, 1996, pp. 48–49)

My suggestions for evidence-based practice are informed by Gould's (1996) insights about research findings and personal outcomes as applied to his own experience with mesothelioma. He was told that his postdiagnosis survival would be eight months, based on research findings. Instead, he lived for more than 20 years postdiagnosis, having a prolific scientific and writing career as an evolutionary paleontologist. I use the concepts that Gould represents in the above quote as the basis for describing clinical reasoning about evidence that balances an understanding of the **central tendency**, or generality, of individuals' attributes, with an understanding of the **individual variation** of these attributes (Tickle-Degnen, 2001). This perspective is consistent with Mattingly and Fleming's (1994) concept of conditional reasoning.

One of the strengths underlying the use of research findings to guide practice with an individual client is that human beings share many similar attributes by virtue of sharing genes and the ecosystem of the earth. As a result, there is a degree of **central tendency** or generality in human behavior and outcomes that can be gleaned from research studies of humans. It is possible that an individual client will respond to assessment and intervention procedures in the same manner in which participants in research studies responded. On the other hand, every individual is unique, having a pattern of life experiences, thoughts, and perceptions in different contexts that matches no other's exactly. In applying research evidence to individuals, we must be

PRACTICE DILEMMA

WHAT COULD REBECCA HAVE DONE?

As an occupational therapy practitioner in an outpatient clinic, what could Rebecca have done with the information about Wanda's background and life? More important, what if Rebecca had heard this information earlier in her sessions with Wanda? Would therapy have been different? Would Rebecca have felt that she had had a more meaningful intervention with Wanda?

highly cognizant of this **individual variation**, assessing at all decision points how this particular client may vary from the others. Understanding this dynamic of generality and variation is the key to using evidence-based practice effectively with all clients, including Wanda.

THE EVIDENCE-BASED PRACTITIONER

Imagine yourself, in the present, as an evidence-based practitioner who is just about to meet the Wanda of Rebecca's clinical experience. As an evidence-based practitioner, you would use scientific reasoning along with the current and best evidence from research studies to support central clinical tasks, such as the selection of appropriate and valid assessment procedures, interventions, and procedures for monitoring clinical progress (Law, 2002; Sackett et al., 2000). It is important to understand that in evidence-based practice, scientific reasoning does not replace reasoning that is informed by clinical experience, theory, core values of practice, and ethics. Nor does the use of research evidence replace the clinical use of information derived from observing clients and talking with their family members or from consulting with experts and peers. Evidence-based clinical reasoning involves the use of all forms of evidence in the pursuit of optimal client outcomes. It is the integration of scientific reasoning with reasoning that has been matured by clinical experience, validated practice theory, and client-centered values and ethics (Egan,

Dubouloz, von Zweck, & Vallerand, 1998; Lee & Miller, 2003; Rappolt, 2003).

ORGANIZING EVIDENCE AROUND CENTRAL CLINICAL TASKS

Table 30.1 shows how, you, the evidence-based practitioner, could organize the search for and interpretation of evidence around central clinical tasks, in general, and, specifically, with respect to Wanda. One of the first clinical tasks that the practitioner faces in working with a client is that of *getting to know the client* with respect to occupational needs and status, to ensure that services are relevant and beneficial specifically for that person. Research evidence that would be relevant to this task includes findings about (1) typical occupational experiences and needs of individuals with personal characteristics or health care conditions similar to the client and (2) the quality of occupational assessment procedures with respect to identifying the unique clinical needs of these types of individuals.

With respect to Wanda, descriptions of the occupational lives of women with Colles' fractures or similar injuries could enhance your understanding of possible issues that Wanda might face in her own life and could generate a discussion with Wanda about her own life. Such a discussion might identify what specific types of in-depth information about Wanda you want to learn in the assessment procedures. After targeting key areas to assess, you could go back to the research literature to find evidence

TABLE 30.1 ORGANIZING EVIDENCE AROUND CLINICAL TASKS WITH WANDA		
Central Clinical Task	**Research Evidence**	**Use of Evidence for Wanda's Specific Case**
I. Get to know a client	A. Typical occupational experiences and needs of clients from populations who can be compared to Wanda B. Quality (e.g., reliability, validity, trustworthiness, usefulness) of occupational assessment procedures for these populations	Generate a discussion with Wanda about her own occupational experiences and needs in comparison with the research samples Select the best assessment method to identify Wanda's unique occupational experiences and needs
II. Choose an effective intervention	Relative effectiveness of different types of interventions designed for these populations	Select, ideally in collaboration with Wanda, a potentially beneficial intervention
III. Monitor response to intervention	Quality of occupational assessment procedures for monitoring changes in clients from these populations with respect to achieving intervention goals	Select the best assessment method for monitoring change in Wanda

about the reliability, validity, trustworthiness, or clinical use-fulness of methods to select the most valuable methods for assessing those areas.

A second central clinical task is that of *choosing an effective intervention* approach and procedure for address-ing the client's specific needs and goals. The research evi-dence that would be relevant to this task includes findings about the relative effectiveness of different types of interven-tions designed for individuals with a particular type of per-sonal characteristic or health care condition. With respect to Wanda, you could use **effectiveness evidence** about interventions designed for individuals with Colles' fractures and similar injuries to select an appropriate intervention. In a client-centered approach, this selection would involve collaboration with Wanda (Tickle-Degnen, 2002a).

A third central clinical task is that of *monitoring response to intervention.* Once an intervention has been chosen and then implemented with the client, its effective-ness for that particular client must be monitored, docu-mented, and revised if necessary. The research evidence that would be relevant to this task includes findings about the quality of occupational assessment procedures with respect to monitoring changes in the client related to progress toward intervention goals. Notice how this task is different from the initial getting-to-know task in which assessment procedures are selected for initial identification of a client's needs and for developing therapeutic goals that are uniquely relevant for the client. Assessment procedures that are valid for that initial assessment might or might not be valid for assessing change. With respect to Wanda, you could use information about the reliability, validity, trust-worthiness, or clinical usefulness of methods for evaluating change in Wanda with respect to the goals established for her occupational therapy.

In addition to the three central clinical tasks discussed here—getting to know the client, choosing an effective intervention, and monitoring response to intervention—there are other important clinical tasks that occupational therapy practitioners undertake with their clients, such as designing and implementing a discharge plan. Regardless of which tasks are central to a particular practitioner's prac-tice or setting, the procedures of evidence-based practice are the same with respect to an emphasis on using *system-atic and reflective analysis of evidence* to guide decision making and clinical procedures toward beneficial outcomes with clients.

THE STEPS OF EVIDENCE-BASED PRACTICE

The evidence-based practitioner systematically integrates research evidence into practice by carrying out a series of steps around each clinical task (Law, 2002; Sackett et al., 2000; Tickle-Degnen, 1999):

1. Writing down an answerable clinical question
2. Gathering current published evidence that might answer the question
3. Appraising the gathered evidence to determine what is the "best" evidence for answering the question
4. Communicating with clients and colleagues about the evidence for decision making

Step 1: Writing an Answerable Clinical Question

The first systematic step, writing down a question, helps the practitioner to focus on the specific type of evidence that would help a clinical task. The question must be written by using key words and terminology that tap into a general body of research literature that may hold an answer to the question and that locate evidence that is relevant to per-forming a particular clinical task with a specific client. An *answerable* question, therefore, must be neither too broad nor too narrow in its focus (Sackett et al., 2000). For occu-pational therapy, this type of question is composed of three elements (Tickle-Degnen, 1999): (1) the *type of evidence* that is needed to address the particular clinical task; (2) a *variable* or attribute that is related to occupational expe-rience, behavior, the occupational therapy process, or out-comes; and (3) a description of the *client's population.*

Type of Evidence

The clinical task dictates what type of evidence is needed. To be able to find the evidence successfully, the practitioner must have a basic working knowledge of the terminology of research designs and methods or use a research meth-ods textbook as a reference manual (e.g., Domholdt, 2005; Portney & Watkins, 2000). The task of getting to know a client involves gathering evidence that is descriptive of the experiences and needs of clients in general (i.e., clients who have been research participants in published studies) and evidence that tests the quality of assessment procedures for determining an individual client's unique experiences and needs. **Descriptive evidence** is published in studies that used a descriptive research design or procedure, includ-ing correlational studies, qualitative interview studies, and participant-observation studies. **Assessment evidence** is published in studies that use a methodological design to study the reliability, validity, or trustworthiness of an assess-ment procedure.

The task of choosing an effective intervention for a client involves gathering evidence that evaluates the effec-tiveness or efficacy of a type of intervention in comparison to alternative interventions or no intervention at all. **Effec-tiveness evidence** is published in studies that used an intervention or treatment research design or procedure, including randomized controlled trials and other forms of experiments, or quasi-experimental and other nonexperi-mental intervention studies.

The task of monitoring response to intervention involves gathering evidence that tests the responsiveness of tests and procedures to clinical change in clients. **Responsiveness evidence** is published in studies that use a repeated measures design across time periods to evaluate the reliability, validity, or trustworthiness of an assessment procedure with respect to monitoring change in clients.

Occupational Variable

In addition to writing an answerable question in language that shows what type of evidence is being sought, the question must be written in language that shows what type of occupational variable or variables are of interest. Variables of interest are attributes of clients that are addressed in occupational therapy, such as their physical or psychosocial functioning, occupational performance, or satisfaction with outcomes. Models and theories of occupation and occupational therapy, such as the Person-Environment-Occupation Model (Law, Cooper, Strong, Stewart, Rigby, & Letts, 1996), as well as more general models of health that encompass an occupational therapy perspective, such as the International Classification of Functioning, Disability & Health (World Health Organization, 2005), provide the language needed to identify occupational variables. The evidence-based practitioner uses reference resources, such as this current edition of *Willard & Spackman's Occupational Therapy,* as a tool for identifying and naming these variables.

Client Population

A final element found in the wording of an answerable clinical question identifies features of the client population of interest, such as the client's clinical condition or diagnosis, gender, ethnicity, age group, and socioeconomic status. The evidence-based practitioner uses clinical knowledge, clinical textbooks, and other practice resources to identify which features of the client's population are important for guiding clinical reasoning and decision making. Important features are those that identify populations or subpopulations of which the client is a member, ensuring that retrieved evidence will be relevant to the client.

Step 2: Gathering Current Published Evidence

Once a clinical question has been written, the practitioner draws on the elements of the written question to search for and gather evidence for finding possible answers to the question. Relevant research is published in a variety of fields: occupational therapy, medicine, nursing, physical therapy, education, psychology, sociology, anthropology, and so on. Consequently, search strategies should tap into the research literature of different disciplines.

Each element of an answerable clinical question contains one or more *key terms* for searching the literature. A whole body of literature can be excluded inadvertently simply because the key terms that are used in the search do not match terminology used by the researchers or the cataloguers of the research literature. Some of the important terms that occupational therapy practitioners use to identify clinical conditions (e.g., sensory integrative disorder) or occupational variables (e.g., occupational performance) are not the most typical terms used to describe or catalogue research studies in the broader literature. Therefore, it is important to generate a list of synonyms for each key term in each element of the question before beginning the search. Fortunately, electronic databases are becoming increasingly flexible in linking terminology across different disciplines. Literature search services such as PubMed (U.S. National Library of Medicine, 2005) provide online tutorials so that evidence-based practitioners can learn how to effectively search the literature with key terms.

Table 30.2 shows examples of questions that you could write with respect to Wanda for the clinical task of getting

---

TABLE 30.2   CLINICAL QUESTIONS, KEY TERMS, AND ALTERNATIVE TERMS (IN PARENTHESES) FOR GUIDING THE SEARCH FOR EVIDENCE ABOUT GETTING TO KNOW CLIENTS LIKE WANDA

Clinical Question	Elements of the Question		
	Type of Evidence	*Occupational Variable*	*Clinical Population*
A. What are the daily life roles of women with a Colles' fracture?	Descriptive (correlational) (client report)	Daily life roles (activities of daily living) (quality of life)	Women with Colles' fracture (middle-age) (wrist)
B. What is a valid method for assessing the occupational goals of clients with hand dysfunction?	Validity (assessment) (methodological)	Occupational goals (goals) (aspirations)	Hand dysfunction (women) (wrist fracture)

to know her. Possible key terms and alternatives that are synonyms, or are broader or more specific terms are listed. With respect to Question A in Table 30.2 ("What are the daily life roles of women with a Colles' fracture?"), the combination of the three terms *descriptive, daily life roles,* and *women with Colles' fracture* returned 0 abstracts from PubMed. Replacing the term *daily life roles* with *activities of daily living* also returned 0 abstracts. The combination of the terms *descriptive, quality of life,* and *women with Colles' fracture* returned a single abstract (Dolan, Torgerson, & Kakarlapudi, 1999). Replacing the term *women with Colles' fracture* with *middle-aged women* returned far too many abstracts to be useful (466), and replacing the term with *wrist* returned one abstract about spinal cord injury.

With respect to Question B ("What is a valid method for assessing the occupational goals of clients with hand dysfunction?"), the terms *validity, occupational goals,* and *hand dysfunction* returned 0 abstracts. The terms *validity, occupational goals,* and *women* returned six abstracts, including one published in the *American Journal of Occupational Therapy* (Melville, Baltic, Bettcher, & Nelson, 2002).

Perhaps after performing an occupational therapy assessment with Wanda, you learned about her interest in writing about her life. If the Colles' fracture had affected her ability to write or type, you might have the following question: "What is an effective intervention for improving writing ability in women with a Colles' fracture?" This and other intervention effectiveness questions are useful for choosing an intervention after the practitioner has gotten to know the client's needs and goals. One search service that is particularly designed to find citations of research related to intervention questions is OTseeker (Bennett et al., 2003, link found at www.otseeker.com). Many searchable databases are helpful (e.g., ProQuest at www.proquest.com or Ovid at www.ovid.com) if you have access to them through library resources.

Finally, you could write a question designed to help you find an assessment for monitoring Wanda's response to intervention, such as "What is a responsive method for assessing recovery of writing ability in women with a Colles' fracture?" Search procedures are similar to those used for the descriptive and assessment questions listed in Table 30.2.

Experience will show you that different combinations of key terms return abstracts with varying success. There is no fail-safe method for returning the most relevant abstracts for answering the questions. An electronic search on key terms is only a partial strategy for retrieval of research evidence. Once a single relevant study is located, the reference list of the study should be examined for other relevant studies. Also you can search the *Related Links* associated with the electronic abstract. Obviously, these searching strategies require time to produce evidence that is useful and comprehensive.

Efficient Gathering of Evidence

Occupational therapy practitioners are very busy and rarely have enough time to complete a reflective, systematic, and thorough review of the literature to guide their clinical tasks with a single client. It must be remembered that the knowledge gained through gathering evidence is cumulative; that is, knowledge of the research literature accrues steadily as more and more clients are seen. Because there is at least a small (sometimes larger) degree, of generality, or central tendency, across clients (e.g., sharing of age, gender, or socioeconomic status), information found with respect to one client or one client group typically can be at least minimally useful for informing your practice with all clients in general. As a result, practitioners can develop routines for collecting and cataloguing evidence for efficient use with future clients. These routines can include the following ones (Tickle-Degnen, 2000a):

1. Periodically search for and retrieve research synthesis articles or practice guidelines that are relevant to your area of practice. These syntheses give a large amount of evidence in a concise and rigorous format.
2. Maintain an up-to-date library of texts that compile current evidence, such as this text and others (e.g., Law, Baum, & Dunn, 2005).
3. Collect and file bibliographies and reference lists from practice conferences and journals.
4. Participate in a journal group or electronic mailing list that discusses relevant evidence.
5. Write down a clinical question every time one is stimulated by a clinical dilemma or need, and then categorize and prioritize the ones most relevant to your practice. This simple exercise will keep you alert to evidence as it arises in your professional life.

The Importance of Gathering Disconfirming Evidence

One goal of gathering research evidence is to determine under which conditions and with which populations occupational therapy assessments are most valid and occupational therapy interventions are most effective. Naturally, there will be some situations in which assessments are less valid and interventions less effective. To provide the best services to clients, the evidence-based practitioner must go beyond one goal, that of the *confirmation* of the value of occupational therapy assessments and interventions, toward a second goal, that of the *disconfirmation* of their value. Having this balanced view about evidence promotes a search that is complete, open-minded, and critical, as opposed to incomplete, closed-minded, and unreflective. Cherished or entrenched practice beliefs and expectations might be disconfirmed or revised, but client outcomes are likely to be maximized. For example, in the case of Wanda, you might find that focusing occupational therapy on her wrist function alone, to the exclusion of her psychosocial

needs, will not be as helpful as you thought it would be (e.g., Chan & Spencer, 2004).

Step 3: Appraising the Evidence

The goal of the search for evidence is to find the *best* possible answer to the clinical question, not a single *correct* answer (Sackett et al., 2000; Tickle-Degnen, 2000b). The evidence may be useful and valuable for guiding work with a client even though it cannot give a definitive prescription of practice. It offers hypotheses to test and possibilities to try out. Before you can use the evidence, however, you must determine systematically just how useful and valuable it is for providing a possible answer to your question.

The Basics of Appraising the Relevance and Trustworthiness of Research Evidence

Evidence that is clinically useful and valuable is both relevant to the clinical task and trustworthy (Domholdt, 2005). There are many excellent resources for guiding the appraisal of research evidence (e.g., Law, 2002; Sackett et al., 2000). Therefore, the presentation here is on the general systematic reasoning that underlies the appraisal process.

APPRAISING THE RELEVANCE OF A RESEARCH STUDY. The **relevance** of a research study is determined by the degree to which it answers the clinical question and by the degree to which its methods fit within the constraints and resources of the practitioner's context of practice (Tickle-Degnen, 2001, 2002b). Rarely will the search for evidence locate a study or set of studies that directly answers the clinical question. The studies were designed to answer the authors' research questions, not your clinical question. The most relevant research study is one that (1) provides the type of evidence that is needed for the clinical task, (2) investigates a variable that is the occupational variable of interest or one highly related to that variable, (3) includes research participants who are members of your client's population, and (4) offers clinical methods that are suitable to your context of practice.

To illustrate the process of examining relevance, we return to the citations retrieved in response to Question B in Table 30.2, "What is a valid method for assessing the occupational goals of clients with hand dysfunction?" One citation was for a paper by Melville and colleagues (2002) that can be retrieved in full text from the American Occupational Therapy Association's Website (www.aota.org). Full text retrieval for papers published in the *American Journal of Occupational Therapy* is available to all members.

The purpose of Melville and colleagues' (2002) research study was to investigate patient perspectives of the validity of the Self-Identified Goal Assessment (SIGA). Patients were interviewed about the usefulness of the instrument with respect to identifying their own goals. This purpose signifies that the study provides **assessment evidence** about occupational goals and thus is relevant with respect to the type of evidence and occupational variable elements of the clinical question. Remember, however, that the key term *women* was used to retrieve this citation after the term *hand dysfunction* failed to retrieve any citations with the relevant type of evidence and occupational variable. As a result, the study is less relevant with respect to the clinical population element of the question. With respect to Wanda, the sample consisted primarily of women; however, they were older and frail, on the average, rather than middle-aged and relatively robust. More important, they were inpatients in a subacute rehabilitation inpatient unit, not outpatients. Items contained in the SIGA were worded around identifying tasks "you would like to work on or improve on in therapy before you go back home" (p. 653). Therefore, although the assessment is relevant for assessing the occupational goals of inpatients, it is not relevant, as worded, for assessing the goals of outpatients.

Although the SIGA might not be the most relevant assessment for Wanda because of some of its wording, its structure is highly practical for your busy outpatient practice. The authors (Melville et al., 2002) found that the mean administration time of the SIGA was 5.6 minutes, compared to 18.8 minutes for administering another possibly relevant goal assessment measure, the Canadian Occupational Performance Measure (COPM; Law et al., 2005). Since the SIGA generally is relevant to your purposes, you should continue with your appraisal of the trustworthiness of the findings of the study.

APPRAISING THE TRUSTWORTHINESS OF A RESEARCH STUDY. Whereas the relevance of a research study is assessed primarily as a degree of fit between your clinical need, as represented in the clinical question, and the methods of the study, the **trustworthiness** of a research study is assessed primarily as a degree of fit between the researcher's research question, or purpose, and the methods of a study. A trustworthy study is one for which the conclusions are defensible with respect to the methods of the study, and there are few if any alternative plausible, scientific explanations for the findings beyond the conclusions drawn from the study and its researchers (Domholdt, 2005). Trustworthiness is enhanced when the researcher carefully and rigorously maintains standards of discovery, description, and explanation (Carpenter & Hammell, 2000).

The most trustworthy research study is one that (1) gathers the type of evidence that achieves the stated purpose, (2) investigates trustworthiness using a variety of methods, and (3) clearly identifies the study's methods, strengths, and limitations with respect to standards of science. The evidence-based practitioner attempts to evaluate the degree to which a descriptive study provides a defensible description of a client or clinical population;

the degree to which an assessment study provides a strong test of the reliability, validity, or usefulness of an assessment procedure; or the degree to which an intervention effectiveness study supports the conclusion that client outcomes were caused by the intervention and not by other factors.

In general, studies that are of interest to occupational therapy practitioners, that is, studies of clinically relevant human performance, behavior, motives, and interests, have limitations in their ability to meet their purposes. For example, individuals from a given clinical population might be rare or have difficulty participating in research procedures. Or the variable of interest might be complex and difficult to describe or assess. Or factors that are not anticipated or understood by the researchers might contribute to the findings, such as unexpected cold weather affecting an individual's response to exercise. Nonetheless, some studies provide stronger evidence with respect to trustworthiness than others because they have attempted to carefully and rigorously address these and other potential limitations (Domholdt, 2005).

With respect to the study of the SIGA by Melville and colleagues (2002), the stated purpose of the study was to investigate patient perspectives of the validity of the SIGA. Clearly, the purpose was to collect **assessment evidence**. To accomplish this purpose, the investigators modeled their design and procedures after those used for validation studies of the COPM. Occupational therapy practitioners administered the SIGA to 20 women and 10 men close to admission in a subacute rehabilitation unit and then once again before discharge. Following each administration, an investigator conducted a structured interview of each patient to gather patient perspectives related to the usefulness of the SIGA in identifying personal therapy-related goals. Data analysis consisted of descriptively analyzing the results of the SIGA administration to clients (e.g., numbers and types of goals identified) and summarizing, quantitatively and qualitatively, the clients' responses to the structured interviews about the usefulness of the SIGA. The investigators compared their results with the results of a previous study of the SIGA as well as results from studies of the COPM, finding results to be similar. They also discussed clearly the strengths and limitations of the study methods and the SIGA and provided suggestions for future validation studies.

From your reading of the SIGA assessment study, you might conclude the following:

1. The study gathered data from a relatively small sample in a manner that used interview procedures that were rigorous for measuring subacute rehabilitation patient perspectives about the SIGA. The investigators were careful to have the SIGA administered by the patient's occupational therapy practitioner and to have an impartial researcher carry out the interviews to gather patient perspectives. The items in the inter-

view were designed to gather evidence that would elicit patient perspectives that were both positive (i.e., confirming) and negative (i.e., disconfirming) with respect to the usefulness of the SIGA.

2. The study compared their findings with the results of a previous study of the SIGA and published studies of the COPM. This comparison was used to determine whether the results of the SIGA study converged toward or diverged from the results of the other studies, enabling an additional test of the trustworthiness of the study findings.

3. The report of the study included clear information about the study's strengths and limitations, including a listing of other validation studies that were needed to provide a stronger test of the validity of the SIGA. In addition, the authors refer the reader to a Website where the reader can download the SIGA and its administration protocol. This access enables the reader to inspect the measure closely and evaluate strengths and weaknesses further.

Although the study was small and limited in scope for testing validity, the research methods were rigorous and generally conformed to standards of sound scientific practice with respect to gathering preliminary evidence on a new measure. It is reasonable to trust the study's findings for the small sample that it tested. Yet it is also reasonable to be cautious in concluding that the findings would be similar for other patients in subacute rehabilitation settings and to be more cautious about conclusions with respect to other clinical populations, such as clients in outpatient settings.

Interpretation of the Results of a Study

Now that you have completed a basic evaluation of the relevance and trustworthiness of the evidence from the study, it is time to examine the results in terms of how they can help answer the clinical question. The general results of the Melville and colleagues' (2002) study were favorable to the validity of the SIGA. Generally, the findings were convergent with other studies on client goal assessments, lending credibility to the usefulness of goal assessments with clients in general. For example, the SIGA identified goals that almost all of the patients tended to remember within 48 hours after administration and to view as their own goals as opposed to goals that others wanted for them. The SIGA was more valid for identifying one's immediately current goals and less valid for identifying goals that were consistently held by the patients. One third of the participants said that they would like to modify their goals 48 hours after administration. The researchers make a defensible argument that the SIGA may be useful as a means for monitoring changing goals and for revising goals as clients engage in therapy over time.

Central tendency research findings, such as averages and majority responses, are helpful for understanding how clients will respond in general, and individual variation

research findings are helpful for anticipating the range of possibilities of how a single client might respond (Glasziou et al., 1998; Tickle-Degnen, 2001). For example, although the majority of clients (29 out of 30) saw the SIGA as useful, there was one individual who found it to be not very useful. And although the SIGA identified goals with which 70% of participants continued to be satisfied 48 hours later, 30% were ready to change their goals at that follow-up period. Melville and colleagues (2002) conducted open-ended interviews and described qualitatively individual responses in a manner that individualizes the quantitative responses. This description helps the reader to understand how participants arrived at their views of the SIGA. In studies with larger sample sizes than that of Melville and colleagues, individual variation information is found in descriptive statistics, such as the ranges and standard deviations (Tickle-Degnen, 2003), and in the results of analyses for different subgroups of research participants, such as separate findings reported for females and males (Tickle-Degnen, 2001).

On the basis of both central tendency and individual variation findings as well as your evaluation of the relevance and trustworthiness of the results, you may interpret the results as indicating that it is possible that a goal assessment procedure similar to the SIGA would be a valid means for getting to know Wanda better. Your reading of Melville and colleagues (2002) points you to the possibility of using the COPM. It would be ideal for you to go through the same evaluation process as outlined here for a study of the SIGA with a study of the COPM. Your new assessment question might be "Is the Canadian Occupational Performance Measure a valid method for assessing the occupational goals of clients with hand dysfunction?" A search using the PubMed database on the key terms *Canadian Occupational Performance Measure* and *hand dysfunction* returns five abstracts, including one that specifically addresses use of the COPM in an intervention effectiveness study of occupational therapy with women who have Colles' fractures (Dekkers & Soballe, 2004). Although the study was designed to collect intervention effectiveness evidence, it provides assessment evidence as well. The *Related Articles* link in PubMed attached to this article links to 102 references that are relevant to the rehabilitation of Colles' fractures. It might be helpful to look over some of these abstracts to gain a better understanding of what Wanda faces with respect to her Colles' fracture.

If there is time, or at a later date, you should evaluate the body of evidence as a whole with respect to answering the clinical question, giving extra weight to the single studies with the strongest evidence. The "best" evidence is the best that can be found, not "best" in the sense of meeting all of the standards. The possible answer this best evidence delivers may be one about which you can feel a high, moderate, or low degree of confidence. You might not have enough time to gather and evaluate enough evidence to form a confident opinion, which is very likely, given, in this scenario, how busy you are as a practitioner in an outpatient clinic. Even with little research evidence about which you feel a modicum of confidence, you may go to the next step of evidence-based practice: communication about the evidence with the client, in this case Wanda, and other individuals who are important to the client.

Step 4: Communicating About the Evidence for Decision Making

The primary purpose of communication about evidence is making wise decisions about therapeutic goals and procedures (Tickle-Degnen, 2000b, 2002c). Wise decisions are ones that are likely to benefit the client and family members and are embraced by client, family members, you (the occupational therapy practitioner), and others of importance to the client, such as other practitioners. Communication that achieves these types of decisions (1) has content that accurately represents the research evidence, including its strengths and weaknesses related to relevance and trustworthiness, (2) involves language that is mutually understandable to all participants, and (3) encourages an open and mutual discussion of information and ideas rather than a closed-ended or unidirectional delivery of information from one individual to another. Even a small amount of evidence in which you have a small degree of confidence can be helpful in decision making if it is presented with these qualities in mind.

Accurate Content About the Evidence

Accurate communication content is balanced in its description of central tendency findings about average or majority responses of research participants, and variation findings about the degree to these participants differ in their responses. Communication with an overfocus on central tendency findings implies that the client surely has the same occupational issues, goals, and outcomes as the majority of research participants or the ones with an average response. For example, a statement that is overfocused on central tendency findings might be the following: "Clients find satisfaction in forming their own goals for therapy" (or, if the evidence pointed in this direction, replacing *satisfaction* with wording associated with dissatisfaction). This example implies that all participants in the research studies were satisfied, which was not the case. On the other hand, communication with an overfocus on variation findings implies that the client surely will have different occupational issues, goals, and outcomes than will the majority or average research participant. For example, consider the statement "Some clients are satisfied and some are not with making their own goals for therapy, because everyone is different and unique." This example fails to inform Wanda about majority or average responses, which she might find helpful in orienting her own response.

An example of a communication that balances central tendency findings with a variation perspective, and therefore is more accurate than the statements in the previous paragraph, would be "Generally, clients have found satisfaction in forming their own goals for therapy. However, some have been more satisfied than others in participating in forming their own goals. Would you like to be involved in forming some of the goals that you and I work toward in therapy?" In this communication, the findings are accurately portrayed, in the past rather than present tense, and the pertinent relevance issue is addressed, enabling Wanda to assess the evidence herself.

Balance in central tendency and variation findings is the basis of communication for all types of evidence. When the evidence is about descriptive, intervention, or **responsiveness evidence**, the same wording issues apply. Wording such as "You must do this intervention because it has been found to work for other clients" is inaccurate, misleading, and contrary to client-centered practice.

Mutually Understandable Language

Information that is understandable is communicated with words and grammar that fit the client's background and comprehension ability. The point is to provide information that supports the client's active participation in clinical decisions. The use of professional terminology (e.g., *functional performance*) or jargon (e.g., *ADL*) should be avoided or explicitly taught to the client. Similarly, scientific, research, and statistical terminology should not be used unless it is of interest to the client. As was shown in the previous sections, findings can be discussed without going into a complex description or explanation.

The main goal of communicating about evidence is to inform the process of decision making, not to elaborate on detailed points that are not necessary for this goal. Information that is understandable and usable is brief and to the point. Pictures and graphs may be used depending on the client's preferred learning style (Redman, 1997).

Encouraging an Open and Mutual Discussion of Information and Ideas

In her review of research on client-centered practice, Law (1998) demonstrated that respect and collaboration elements of the therapeutic relationship were important predictors of rehabilitation outcome, just as they are in all health care relationships (Martin, Garske, & Davis, 2000). Practitioners and clients come to an understanding of one another's perspectives through communication and the therapeutic activities they do with one another (Crepeau, 1991; Mattingly & Fleming, 1994). When the practitioner begins a discussion about evidence, the wording should reflect that the discussion will be about open-ended probabilities and possibilities, rather than about closed-ended certainties.

In communicating with Wanda about the possibility of performing an assessment of her occupational goals,

building on the communication qualities described previously, you might say, "Wanda, there are some questions I could ask you about your goals for therapy that might be helpful for me getting to know more about what is important to you, so that we can focus on those things in therapy. In a research study, most patients were satisfied with these questions for identifying their goals, although some were not satisfied. It was a fairly small study of people who were older than you and staying in a hospital, but the general method seems useful for our needs right now. Do you have any thoughts about me asking questions about your goals for therapy?" Later, if the two of you try out the assessment methods, modified for Wanda's situation, you could suggest to Wanda that you repeat similar questions at each session, since the research study by Melville and colleagues (2002) suggested that people may change their goals quickly.

ETHICS, PRACTICE VALUES, AND EVIDENCE-BASED PRACTICE

As has been put forward in this chapter, evidence-based practice emerges from the core values and ethics of occupational therapy (American Occupational Therapy Association, 2000; Christiansen & Lou, 2001; Kanny, 1993). Evidence-based practice occurs in a respectful, truthful, and collaborative relationship with the client and with those acting on the client's behalf. Clients are viewed as active contributors to the planning and intervention process of therapy rather than as passive recipients of information or services (Law, Baptiste, & Mills, 1995). To be active rather than passive, that is, to act with as much autonomy as possible and the least amount of dependency, clients and those acting on their behalf must be informed rather than uninformed or misinformed. To be an informed client means to know the meaning of one's occupational status in relationship to one's quality of life, to know the nature and quality of possible occupational therapy assessments to be undertaken, to know the quality and probable outcomes of relevant interventions, and to have the means to assess one's own progress toward meaningful outcomes. Once informed, clients and those acting on their behalf can reason and act with the degree of autonomy of which they are capable.

One implication of autonomous reasoning and action is that clients can choose to participate or not participate in occupational therapy assessments and interventions. Likewise, family members or other health practitioners may decide to encourage or discourage client participation. Evidence-based practice is not about the imposition of the will of one individual on the will of the other, but rather is a mutual search for and discussion about information that will aid informed, wise decision making. The practitioner's responsibility is to provide information in such a manner that reasoned decision making is maximized.

EMBRACING AN IDEOLOGY OF CHANGE IN OCCUPATIONAL THERAPY KNOWLEDGE AND PRACTICE

Perhaps one of the greatest challenges of evidence-based practice is that what is considered to be the best evidence to answer a clinical question can change as more research is conducted. What might be the best information for working with Wanda today might be substandard a year from now. That there is no fixed answer to how to work with people like Wanda requires an approach to occupational therapy education, practice, and theory development that embraces an ideology of change and development. We certainly embrace this ideology for our clients, expecting them to be open to, and changing with, the new circumstances of their lives, to losses, and to gains.

How can we embrace this ideology of change? First, we must recognize that knowledge is not static and closed, but rather dynamic and open (Kaplan, 1964/1998). Strategies for using dynamic and open evidence begin with recognizing that knowing how to learn on a daily basis is a fundamental skill of an occupational therapy practitioner. Expertise is not knowing facts but rather knowing how to find out probabilistic answers to complex questions in a manner that can help us to make practical decisions (Mattingly & Fleming, 1994; Tickle-Degnen & Bedell, 2003).

Second, we must advocate for resources to do evidence-based practice. Using an ever-changing pool of evidence requires time and institutional, organizational, and government support in the form of policy, training, and infrastructure. Without this time and support at a systemic level, it is very difficult for individual practitioners to be evidence-based (Illott, 2003).

By adapting to changing circumstances and changing evidence, occupational therapy will continue to be a vibrant, healthy, and important force in the health of individuals with occupational needs. The tools and strategies of evidence-based practice harness this change to the benefit of our clients and our own professional development.

PROVOCATIVE QUESTIONS

1. What is the evidence that hand injury or hand therapy is interrelated with psychosocial aspects of clients' lives and experiences?

2. What should Rebecca do with the information that Wanda disclosed to her during therapy?

3. Imagine that you have a new client with a diagnosis of adrenoleukodystrophy, a diagnosis that is unfamiliar to you. What steps would you take to find evidence that would provide you with a better understanding of the needs of clients from this population?

4. As you are developing an intervention plan, you can find no evidence specifically about the effectiveness of occupational therapy on outcomes for individuals with adrenoleukodystrophy. What should you do as an evidence-based practitioner?

5. In a clinical setting that does not provide organizational support for evidence-based practice, what strategies would you develop to support your evidence-based practice?

Learning Objectives

After reading this chapter, you will be able to:

1. Define the terms *abuse, neglect,* and *exploitation,* and give examples of each of these as they relate to people with disabilities across the life course.
2. Recognize the main risk factors that contribute to clients' vulnerability and know ways to identify these in individuals' lives.
3. Identify ways in which abuse and neglect may be prevented through occupational therapy.
4. Understand the law and the American Occupational Therapy Association's standards of practice regarding an occupational therapy practitioner's role in responding to suspected abuse or neglect.

INTRODUCTION

Occupational therapy's domain of practice and primary mission is the promotion of individuals' engagement in meaningful activities and roles within their homes and communities (American Occupational Therapy Association, 2002). Preventing the abuse, neglect, and exploitation of occupational therapy clients fulfills two central missions of the profession: helping people to pursue occupational goals and protecting them from harm. A sense of physical and emotional safety is needed for clients to work toward the achievement of many occupational performance goals (Christiansen & Townsend, 2004). The Occupational Therapy Code of Ethics—2005 cites beneficence, or the demonstration of concern for clients' well-being, as its first principle (American Occupational Therapy Association, 2005). Clearly, occupational therapy practitioners have a mandate to understand the dynamics that result in harm to clients and to join with colleagues from other helping disciplines to strive to eliminate this public health problem. The purpose of this chapter is to assist the reader in understanding why and how abuse occurs, to help prevent such situations from developing, and to recognize and respond to abusive situations affecting a variety of client populations.

MALTREATMENT AND OCCUPATIONAL PERFORMANCE

For many individuals with disabilities, experiences of maltreatment by family members or paid caregivers result in long-term reductions in their occupational opportunities. Maltreatment includes economic exploitation, neglect, and various forms of abuse (see Box 31.1.) Research has shown links between maltreatment early in life and lifelong neurological, developmental, and psychiatric problems (Egeland, Sroufe & Erickson, 1983; Haskett & Kistner, 1991; Hoffman-Plotkin & Twentyman, 1984; Jaudes & Diamond, 1985; Manly, Kim, Rogosh, & Cicchetti, 2001; Pears & Fisher, 2005; Putnam, 2003). Individuals with disabilities who are enduring maltreatment might avoid opportunities to participate in occupational roles because of fear of punishment, or they might have restricted access to resources and contexts requisite to many activities (Milberger et al., 2003; Ryan, Salenblatt, Schiappacasse, & Maly, 2001; Stancliff, 1997).

DISABILITY: A RISK FACTOR FOR ABUSE ACROSS THE LIFE COURSE

People of all ages with disabilities are at significantly increased risk of neglect, abuse, and exploitation when compared with those whose abilities are typical (McAllister, 2000; Milberger et al., 2003; Spencer et al., 2005; Strand, Benzein & Saveman, 2004). A study comparing the prevalence of maltreatment in school children found a rate of 11% among nondisabled children and a rate of 31% in the disabled group (Sullivan & Knutson, 2000). In 47% of the cases, the child's disability was thought to have been a causative factor in the abuse; in over 14% of the cases, disabilities were the result of abuse. In a survey of agencies serving survivors of sexual abuse and assault, Sobsey (as cited by Lumley & Miltenberger, 1997) found that 54% of the clients had cognitive impairment. A study of women with mild mental retardation found that 71% of the sample had experienced forced or coerced sexual contact (Stroms-

---

BOX 31.1   **DEFINITIONS OF TERMS**

- **Economic exploitation** is the unethical use or taking of another person's money or property, either without their knowledge or through the use of undue influence. Theft and coercion to "give" gifts or loans are examples of this.
- **Neglect** is the withholding of nutrition, shelter, clothing, or medical care, such that a dependent person's health is endangered. Undersupervision and abandonment are included in this category.
- **Self-neglect** occurs when an older person engages in behavior that places his or her safety or health in danger without the cognitive capacity or judgment to anticipate consequences.

- **Physical abuse** includes punching, shaking, kicking, biting, throwing, burning, and other forms of injurious punishment.
- **Sexual abuse** is any seduction, coercion, or forcing of a person to observe or participate in sexual activity for the sexual gratification of a more powerful individual.
- **Psychological abuse** involves coercion and punishment through threats of harm to the individual or those he or she cares about, humiliation, or otherwise deliberately undermining a person's self-esteem and well-being.

ness, 1993). Research involving 177 women with physical disabilities, most of whom lived independently, found that 56% of the sample had experienced some form of abuse (Milberger et al., 2003). Results of a national study indicated that at least 450,000 elderly Americans experienced abuse, neglect and/or exploitation in 1996 (National Center on Elder Abuse, 1998). The National Center on Elder Abuse (1998) estimated that for every case of elder abuse, neglect, or financial exploitation reported to state authorities, about five others have gone unreported.

Studies have shown that abuse occurs in many settings: homes, schools, work settings, group homes, and residential care facilities (Lumley & Miltenberger, 1997; Marchetti & McCartney, 1990). The home is the most common site of maltreatment, although abuse in institutional settings is also well documented (Bonner, Crow, & Hensley, 1997; National Center on Elder Abuse, 1998). Data regarding the incidence of abuse and neglect are not complete or entirely accurate, due to significant underreporting and limitations in data collection (Bonner et al., 1997; Kenny, 2001; Oktay & Tompkins, 2004). It is very likely that the actual numbers of people suffering mistreatment are much greater than can be established through current methods of data collection (National Center on Elder Abuse, 1998).

CAUSES OF ABUSE AND NEGLECT

Abuse, neglect, and exploitation are the outcomes of a dynamic interplay of factors that involve the environment, the perpetrator, and the victim (Hoffman-Plotkin & Twentyman, 1984; McAllister, 2000). Only by understanding each of these domains and how they interact can problems of mistreatment be prevented and methods of dealing with mistreatment be improved.

Environmental Risk Factors

Prevailing societal, community, and family attitudes about how to resolve conflict and the value of persons with disabilities influence individuals' behaviors. In the dominant culture of the United States, individualism is generally valued over collectivism (Kondo, 2004). Individuals and families are encouraged to take responsibility for themselves, and privacy is highly valued. Self-reliance and achievement through independent effort are also prized. These values have helped the United States to become the greatest economic power the world has ever known. These values might also have contributed to the isolation and disparagement of people who have needs that require a more interdependent way of life. Additionally, contemporary American culture promotes violence as an acceptable solution for conflict, a means of establishing power, and even a source of entertainment (Noguera, 2001; Prothrow-Stith, 1991). The prevailing cultural conditions

result in an environment that supports the use of aggression in American homes and institutions.

The more immediate community culture can have a greater impact on individuals' behavior than the culture that is found at the national level. Some neighborhoods and towns are cohesive and interactive, resulting in available positive support and social scrutiny, a combination that tends to reduce antisocial behavior (Sampson & Groves, 1989). In other communities, neighbors might not know one another at all or might harbor mistrust and dislike of each other. In such communities, there might be no one to turn to in times of crisis and no sense of mutual concern or interest. In communities where people commonly verbally and/or physically batter one another or where neighbors rarely interact, all people are at increased risk of victimization (Vondra, 1990).

Poverty is a risk factor for many public health problems, including domestic violence and neglect. It correlates positively with increased rates of child abuse and neglect (Coulton, Korbin, Su, & Chow, 1995; Sedlak & Broadhurst, 1996; U.S. Department of Health and Human Services, 2000). Additionally, unemployment (Milberger et al., 2003) and lower income (Oktay & Tompkins, 2004) are positively correlated with maltreatment of adults with disabilities. Although poverty is linked to increased levels of abuse, high levels of social integration and community morale appear to be mitigating factors that can reduce levels of child abuse even in low-income neighborhoods (Garbarino & Kostelny, 1992).

Risk Factors Related to Caregivers

People who perpetrate abuse range from the overwhelmed parent or caregiver who occasionally reacts harshly out of exhaustion and despair to the calculating sociopath who deliberately seeks and systematically hurts victims (MacNamara, 1992). Some caregivers are neglectful out of ignorance of the medical or daily care needs of the individual in their care or because of a lack of resources. Sometimes family caregivers have health or life complications of their own and are unable to manage the demands of juggling a complex array of responsibilities (McAllister, 2000). Some caregivers harbor feelings of anger and resentment based on a history of conflict with a spouse or parent who is now in their care.

Social isolation, a critical risk factor in maltreatment, can be a function of the person as well as the environment. Many caregivers, both family members and paid staff, work alone for long hours, resulting in increased stress and a lack of oversight by outsiders. If a caregiver has limited contact with others who are emotionally and functionally supportive, the risk of abuse increases (Windham, 2000). Caregivers who seek and utilize social supports within the family or community are reducing the risk of maltreatment as well as increasing their job satisfaction (Gerits, Derksen, & Verbruggen, 2004).

Caregivers who have little sensitivity to others' feelings or perspectives, limited capacity for putting others' needs before their own, and/or a low tolerance for frustration are at increased risk of acting abusively. People who abuse alcohol or drugs or who have other mental health problems such as depression or borderline personality disorder are more prone to act abusively than is the typical caregiver. An adolescent mother is at increased risk of mistreating her child, just by virtue of being young, both psychologically and neurologically (Strauch, 2003). As with all risk factors, these personal characteristics are not reliable predictors. However, they are factors that, when combined with other features of the situation, can influence outcomes.

Risk Factors Related to the Client

A trait that is shared by people who become victims of domestic or institutional abuse or neglect is dependence on others for meeting basic needs, such as shelter, food, clothing, medical care, or social contact. This group includes all infants and children, with or without typical development, as well as adolescents and adults with significant disabilities and the elderly. The longer the duration of a person's dependency, the longer is the duration of increased risk of maltreatment.

The more fragile an individual's health, the greater are the chances of long-term harm from maltreatment. Infants and young children are at higher risk for life-threatening injuries than are older children and adolescents (Sedlak & Broadhurst, 1996). Of all elders, those aged 80 years and older were abused at two to three times the rate of younger respondents in a national sample (National Center on Elder Abuse, 1998).

People who are unable to report or resist mistreatment are at increased risk of abuse and neglect for multiple reasons (Lumley & Miltenberger, 1997; Vondra, 1990). Individuals with cognitive disabilities are often acculturated to be passive and compliant (Tharinger, Horton, & Millea, 1990). They are expected to trust and obey a wide array of caregivers and are often rewarded for being "good" (Lumley & Miltenberger, 1997). Assertive disagreement or resistance to following directives may be construed as problematic or even symptomatic and may be treated accordingly. In addition to issues of acculturation, many people with limited independence have severely restricted social lives and are eager to please their caregivers, whom they may construe as potential friends.

If an abusive or exploitative caregiver provides essential assistance, the care recipient might be unable or unwilling to risk the loss of services, even if it means enduring mistreatment (Milberger et al., 2003). In some cases, even if victimized individuals would like to have help, their disabilities and social isolation prevent effective communication of the problem.

In addition to prolonged dependence, some individuals have inherent and learned traits or behaviors that may trigger aggression by a susceptible caregiver. Dependent individuals who resist attempts to provide care and those who are more active, for example, may elicit aggressive reactions more often than do passive individuals (Strand et al., 2003). Clients who have cognitive deficits might strike or otherwise hurt caregivers, who might then retaliate (Oktay & Tomkins, 2004; Strand et al., 2004).

However, current evidence indicates that caregiver characteristics are more important in predicting abuse than are the level of dependence and the severity of impairment of the care recipient. One recent study of characteristics of children who were abused concluded that parental attitudes toward the children were more predictive of abuse than was the type or severity of the child's health problems (Sidebotham & Heron, 2003). Personal care assistants of adults with disabilities are more likely to abuse if they are male, are inexperienced, work long hours, or have a low income (Oktay & Tompkins, 2004). An exception to this trend may be women with hearing impairment, which may be a type of disability that, in and of itself, increases the risk of abuse, regardless of caregiver characteristics (Milberger et al., 2003).

PREVENTING MISTREATMENT

MacNamara (1992, p. 4) states, "One reason for the persistence of the problem [of abuse] is that it tends to be treated episodically and not systematically." Occupational therapy practitioners can influence the environment, including the caregivers, and the client. Helping clients to develop skills that reduce dependency in activities of daily living reduces caregivers' stress and necessary intrusion. The routine involvement of people with disabilities in community functions also reduces the risk of victimization. Not only is social isolation reduced, but the disabled individual has opportunities to develop social and decision-making skills that are antithetical to acting like a victim.

Most abuse is caused by someone familiar with access to the victim (Sobsey & Doe, 1991). Caregivers can benefit from a supportive educational approach that includes hands-on training and performance evaluation, which facilitates a sense of empowerment along with needed skills. Helping family caregivers to develop a schedule of family, friends, or community members who can regularly visit with, assist, or provide respite to the caregiver eases isolation and reduces the risk of abuse at home. Connecting families with consumer support groups and social service agencies that provide professional respite, day programs, supervised group living, transportation, or other services to disabled individuals is another way of reducing the risk of abuse and neglect.

When clients enter institutional care, their likelihood of experiencing sexual abuse increases significantly (Lumley & Miltenberger, 1997). Occupational therapy practitioners can provide needed support and information to institutional workers via regular consultative visits and during direct intervention (Marchetti & McCartney, 1990). An

even more sustaining approach is to advise managers on ways to maximize the quality of staffing. Establishing shifts that are predictable and of reasonable duration, providing frequent and regular supervision, and requiring staff development and training help to reduce the risk of abuse in institutional settings (MacNamara, 1992).

Another level of preventive intervention lies in the larger environment. Occupational therapy practitioners are positioned to help facilities to develop programs that bring community members into the facility and take people with disabilities out into the community. Occupational therapy practitioners can educate members of community agencies and businesses regarding opportunities to include people with developmental disabilities and their caregivers. Such groups include churches, Junior League, Lions Club, Rotary Club, Boy and Girl Scouts, Small Business Associations, groups of artists and musicians, and Junior Achievement. Institutions that invite the public in via volunteer opportunities and open social events and that establish a high profile in the community provide a healthier environment for both staff members and residents.

Assertiveness training that specifically teaches individuals to recognize and respond to dangerous or exploitative situations can help clients to avoid victimization (Khemka & Hickson, 2000; Lumley & Miltenberger, 1997). Sexuality education is a necessary and often overlooked intervention for people with developmental disabilities (Lumley & Miltenberger, 1997; Tharinger, Horton & Millea, 1990). It is impossible for clients and caregivers to make good choices without adequate information. Occupational therapy practitioners who have completed appropriate educational preparation can make important contributions here, either independently or in conjunction with other professionals on the intervention team.

IDENTIFYING AND RESPONDING TO MISTREATMENT

Unfortunately, it is not always possible to prevent abuse from occurring. Occupational therapy practitioners can play an effective role in identifying and intervening in existing cases of abuse. The presence of practitioners in institutional, community, and home settings allows them to continuously evaluate clients' interactions with paid and family caregivers, friends, and work associates during routine activities. Often, the signs of ongoing physical or sexual abuse are subtle and indirect, especially if the client has limited language, is intimidated, or is habitually compliant. Practitioners must be sensitive to changes in demeanor and nonverbal communications to evaluate the possibility of abuse (Tharinger et al., 1990). Client behaviors that may indicate abuse include acting anxious or out of character in the presence of a particular individual. Occupational therapy practitioners should be vigilant for physical evidence of abuse, such as bruises or other types of injury that are not logically explained. Interactions between the caregiver and client may indicate patterns of domination, intimidation, or neglect. Caregivers should be evaluated by interview and observation for signs of distress and burnout, anger, or lack of preparedness for the tasks for which they are responsible. The caregivers' work-related social supports and resources that they can access in emergencies are part of the evaluation as well.

PRACTICE DILEMMA: Iris and the "Teasing" Co-Worker

Iris was a 23-year-old woman with Down syndrome who was in her second month of a competitive employment position in a discount retail store, where she stocked shelves and swept the floor. Iris received weekly job coaching by an occupational therapy practitioner, who was impressed by Iris's developing work habits and social skills. One week, the practitioner noticed that Iris appeared subdued and preoccupied. When she asked Iris how things were going and how she was feeling, Iris characteristically answered, "Fine." During the following visit, the practitioner learned that Iris had missed two days of work in the previous week. The occupational therapy practitioner observed Iris and a male coworker, Bob, as they stocked shelves. Bob teased Iris by "accidentally" knocking items off the shelves so that she would then bend over to pick them up as he watched. He called her "hot stuff," which made Iris blush and look uncomfortable. When asked privately how she felt about working with Bob, Iris replied, "He bugs me!"

Questions for Reflection and Discussion

◆ What are three signs that there is risk of abuse in this situation?

◆ What is the occupational therapy practitioner's responsibility in this situation?

◆ How could the occupational therapy practitioner intervene by facilitating changes in the environment?

◆ How could the occupational therapy practitioner intervene by facilitating changes in the client's behavior?

Practitioners in all 50 states are legally mandated to refer cases of suspected abuse or neglect to the appropriate agency and to know their state's regulations and procedures for reporting suspected abuse (Child Welfare Information Gateway, 2005; Schauer, 1995; Tharinger et al., 1990). In many cases, a decision to refer a family to Child or Adult Protective Services is made by a team, and the team's leader makes the report. However, in the absence of a team decision, an individual practitioner who has reason to suspect maltreatment is legally and ethically responsible for making a referral independently. People who report reasonable concerns to protective services are legally protected from prosecution, and their identity will be held confidential. If abuse, neglect, or exploitation is suspected, the occupational therapy practitioner should call the local branch of the appropriate state agency. Contact information for this is available in the telephone book in the government agencies and emergency numbers sections and via the Internet.

All reports that are made in good faith are acceptable, even if it becomes apparent that maltreatment has not occurred. Referrals involve making a telephone call followed by a letter that outlines the client's name, age, and address and a summary of the reasons for concern. Reports are categorized by severity and type, and investigations are scheduled accordingly. The occupational therapy practitioner should submit repeated reports if continued observations of the problem behaviors occur; multiple referrals are sometimes needed before a case qualifies for an in-depth Protective Services evaluation or a legal intervention. The average time period between referral and the initiation of intervention services is 29 days (U.S. Department of Health and Human Services, 2000).

Approximately 21% of reported child abuse and neglect cases reach the courts (U.S. Department of Health and Human Services, 2000). Available figures indicate that 7% of cases of elder abuse are resolved in court (National Center on Elder Abuse, 1998). Judges rely on professionals' notes and reports to make decisions about cases of alleged abuse. For documentation to serve as credible evidence in court, it must be deemed reliable and valid (Barth & Sullivan, 1985; Kreitzer, 1981). Reliable evidence is documented close to the event's occurrence and, when possible, by more than one observer. Repeated observations or measures taken over a period of time strengthen the report. Valid evidence employs a variety of direct measures, involves standardized tests as much as possible, and is based on objective information rather than the practitioner's interpretation.

Involving Protective Services in a case adds another facet to the work of the treatment team. The role of Protective Services is to screen cases for possible abuse or neglect; evaluate those whose problems meet intake criteria; and intervene in identified cases of abuse, neglect, or exploitation. Protective Services agencies offer or arrange for an array of services to families who are admitted to the caseload. Services may include case management, mental health counseling, drug and alcohol treatment, in-home assistance, respite care, and assistance with housing and medical care (National Center on Elder Abuse, 1998; U.S. Department of Health and Human Services, 2000).

Protective Services agencies are frequently criticized by the media and the community at large. They are typically overburdened and underfunded (Faller, 1985; Roche et al., 2000). Protective Services caseworkers are typically paraprofessionals who carry large, emotionally stressful caseloads and find limited resources to meet clients' complex needs. They earn relatively low wages for long hours of stressful and often dangerous work. Occupational practitioners whose clients are involved with Child or Adult Protective Services should strive to initiate and maintain regular contact with their clients' caseworkers to share information and form a positive working relationship. Protective Services workers can in turn support therapeutic efforts by encouraging clients and their caregivers to attend appointments and work with the practitioner.

Occupational therapy practitioners are strategically positioned, have the knowledge and skills, and are ethically and legally mandated to address this public health concern at every level. For society to reach the goal of full inclusion, it is essential to create and maintain environments that are free of abuse and exploitation. All occupational therapy practitioners should be proficient in preventing, identifying, and intervening in cases of suspected or actual abuse.

OCCUPATIONAL THERAPY INTERVENTION FOR ABUSED CHILDREN AND THEIR CAREGIVERS

Effective intervention with victimized clients and their families or caregivers requires an interdisciplinary team approach that addresses the needs of the system as well as the needs of individual family members. In many settings, the team includes social workers, teachers, psychologists, physicians, nurses, speech therapists, and/or physical therapists.

Intervention for the Caregivers or Parents

The occupational therapy practitioner can assist caregivers by helping them to identify and build on their family's strengths, teaching concepts and skills that may be lacking, and assisting with building a natural social support system. The development of a support system begins with the caregiver-practitioner relationship, which is facilitated via the practitioner's communication of caring and respect. When the caregiver views the practitioner as someone in whom to trust and confide and as someone who will try to help, a milestone has been reached. Edu-

cational and support groups for parents or other caregivers help participants to learn that they are not uniquely troubled, and they often discover helpful solutions to commonly experienced problems. Even more enduring forms of support can be developed by helping parents or other caregivers to develop mutual relationships with reliable friends, family, and community resources.

Caregiver education must be customized to fit the developmental, cognitive, physical, social, and emotional abilities of the client and the context of his or her life. Bearing this in mind, caregiver education could include behavior management techniques such as praising approximations of desirable behaviors, sticker charting, and gentle time-out. Information related about the client's developmental needs and capacities for self-regulation and safety can reduce frustration and danger caused by caregivers' unrealistic expectations. Role-playing and practicing new skills in client-caregiver activity-based sessions help to consolidate new knowledge and skills. Assertiveness training can help parents and other caregivers to improve general communication abilities and facilitate empowerment. Education and practice of crisis prevention techniques (i.e. list making; financial budgeting; planning work, leisure, and health care obligations around daily care and transportation resource availability) is often useful. Carefully timed and tactful referral for further help such as that afforded by psychotherapists, day care programs, adult educational or vocational training programs, and financial advisors can also significantly influence family functioning.

Intervention for the Child

Emotional bonding with a caring adult is requisite to healthy personality development (Bowlby, 1988; Feeny, 1996; Hazan & Zeifman, 1999; Waters & Stroufe, 1983) and subsequent social relationships (Schneider, Atkinson & Tardif, 2001). Ideally, this type of relationship should be developed with a caregiver who is a permanent member of the child's world. Sometimes the practitioner must assist the child in establishing initial trust in therapy and then transferring this new ability to a caregiver in the larger world. The practitioner may facilitate a child's ability to form relationships through activities found in healthy parent-child interactions, including cuddling and holding, feeding, grooming, and teaching developmentally appropriate skills. Reliability, gentleness, and communication of caring are essential features in this kind of therapy. Approaches for addressing the abused child's psychosocial needs may be combined with occupational therapy techniques used in treating other developmental needs, such as motor skills, dressing, and eating. Therapeutic activities based on sensory integration theory, neurodevelopmental treatment, and behavioral approaches are easily performed with attention to the nature and quality of the therapeutic relationship.

Intervention for the Parent-Child Relationship

The most desirable outcome for troubled families is reunification of children and parents, given that a safe and caring environment has been established. As the parent and child become better able to receive and respond to support from the practitioner, the likelihood of facilitating their own positive interactions increases. The occupational therapy practitioner can select activities to elicit appropriate caregiving behaviors by grading the amount of interaction and external structure required. Activities should be selected for appropriateness in terms of the parent's and the child's developmental levels and should be presented in a supportive mode. The practitioner might need to demonstrate and teach some of the activities initially. In all activities, gentle physical contact, pleasant conversation, and mutual enjoyment are the main goals. The occupational therapy practitioner can also use parent-child sessions to teach concepts of child development. Parent-child sessions can also allow parents to observe and practice behavior management skills, such as praising and correcting behaviors.

OCCUPATIONAL THERAPY INTERVENTION FOR ADULT CLIENTS

Occupational therapy intervention with adult clients who have experienced abuse or neglect is focused largely on securing an appropriate environment and, when possible, helping the client to achieve knowledge and skills to reduce future risk. The occupational therapy practitioner can be instrumental in determining the appropriate levels of support needed by an adult with cognitive or physical disabilities and can work with the intervention team to help locate or design a safe living situation that maximizes opportunities for participation. Many clients benefit from occupational therapy assistance in establishing a durable and accessible network of friends, thereby reducing social isolation. This may be achieved by connecting clients and caregivers with groups who share the client's interests, such as social clubs and activity groups. Communication skills training and practice can also be useful for improving clients' ability to express wants, set limits, and ask for help. Occupational therapy practitioners working in home and residential settings can help to prevent abuse by educating and supporting the primary caregivers. People in these roles are at risk for caregiver burnout, a problem that can be decreased through improved working conditions, predictable scheduling, appropriate knowledge and skills, and the empathy and respect of others (Marchetti & McCartney, 1990). Clients or caregivers who demonstrate severe or chronic emotional distress should be referred for mental health evaluation by appropriate professionals.

CASE STUDY: *Hannah's "Evil Temper"*

Two-year-old Hannah was referred by her pediatrician for an occupational therapy evaluation to determine her developmental status, which was monitored annually at an outpatient clinic for prematurely born infants and toddlers. During the preassessment interview, Hannah's mother, Joyce, commented that her daughter had "an evil temper, just like her dad." Joyce was especially distressed because Hannah's attendance at day care was in jeopardy due to her having bitten other toddlers. "If I don't have day care, I'll lose my job. Her dad doesn't even help with child support. I'll end up on the street!" lamented Joyce.

As part of the developmental evaluation, the practitioner asked Joyce to entice Hannah to play with a toy box with multiple buttons and levers that released pop-up toy figures. Joyce showed the box to Hannah, who became excited and reached for the toy. Joyce quickly became frustrated by Hannah's inability to immediately use the levers and buttons and abruptly pulled the toy out of Hannah's reach to play with the box herself. Hannah then hit her mother and collapsed in anguish as Joyce rolled her eyes and said, "See what I mean? She's violent!"

Results of the developmental evaluation indicated that Hannah's gross motor development was appropriate but her fine motor, language and cognitive-adaptive skills were below expected levels. Added to these concerns were observed risk factors for child abuse or neglect. Joyce had

demonstrated a limited understanding of Hannah's developmental level and needs, was feeling frustrated, and negatively associated Hannah's behavior with that of the child's father. Joyce interacted with Hannah in an insensitive manner and seemed preoccupied by her own needs. Money was a concern, and a financial crisis was possible. Hannah's day care providers had assessed her aggressive behavior as beyond that of typical children in severity and frequency. Hannah had trouble communicating, causing her frustration and increased dependence on others' ability to discern her needs and wants.

The occupational therapist was pleased that this child and mother had come into care at this time, before more serious problems had developed. At the occupational therapist's recommendation, the medical team agreed to refer Joyce to an outpatient social worker who would work with her to evaluate her needs and resources related to finances and housing and who could connect Joyce with legal advice regarding child support. Joyce was receptive to this and to a referral to state-funded early childhood services that would provide needed developmental services and parental education. The occupational therapist obtained Joyce's written permission to contact Hannah's day care providers and offered them up to two hours of consultation related to helping Hannah participate successfully and safely in day care.

CASE STUDY: *Mrs. Nash's Missing Money*

Jonita was an occupational therapy practitioner working in home health. Mrs. Nash, her client, was recovering from a cerebrovascular accident. Mrs. Nash lived alone, with the occasional assistance of her son and his family and twice-weekly personal care assistance from a local agency. During one session, Jonita and Mrs. Nash were working on money management, cognitive skills, and fine motor skills by balancing Mrs. Nash's checkbook together. After helping Mrs. Nash to assemble and arrange the needed materials for the task and then problem solving how to open the envelopes from three months of unopened bank receipts, they began the process of reviewing the bank statements and comparing entries with those in the checkbook. It soon became evident that the balance shown in the checkbook did not remotely match that from the bank. Several hundred-dollar withdrawals had been made, reducing Mrs. Nash's funds dramatically. Mrs. Nash was agitated by this discovery and could not recall having made the transactions. She expressed concern that she was "losing her mind."

After carefully looking at the dates of the withdrawals, Jonita and Mrs. Nash realized that the withdrawals had occurred on days when Mrs. Nash was driven to hair salon appointments by the personal care assistant. Jonita learned that Mrs. Nash had given her debit card to the caregiver to withdraw cash from the ATM while driving to the appointments. It was likely that extra cash had been stolen from the account at those times.

Jonita and Mrs. Nash worked together to make a plan of action that included (1) terminating the offending caregiver's employment and recruiting a replacement, (2) going to the bank to change her debit card and checking account numbers, (3) agreeing that Mrs. Nash would henceforth balance her checkbook within two days of receiving a statement, (4) involving Mrs. Nash's son in helping to screen potential paid caregivers and taking Mrs. Nash to the bank weekly, and (5) obtaining and reviewing educational materials from the bank and online resources to learn about financial exploitation of elders and ways to prevent this.

CONCLUSION

Occupational therapy practitioners establish helping relationships with clients in settings that range from institutions of care to the community and home. In addition to working directly with individual clients, contemporary occupational therapy practitioners interact with caregivers, administrators, and colleagues in other disciplines to create environments that support individuals' optimal occupational performance. Such a wide span of influence allows occupational therapy practitioners to initiate and guide systemic improvements that are essential to preventing and ameliorating victimization.

PROVOCATIVE QUESTIONS

1. Occasionally, colleagues from other disciplines are surprised and dismayed that the team occupational therapy practitioner is raising concerns about potential abuse of a client. What would you say if someone asked "Why are you so concerned about this? Isn't that the social worker's role?"
2. What is the potential impact of abuse or neglect on an elderly individual's occupational performance?

VI

THE THERAPEUTIC PROCESS

" Therapists work to create significant experiences for their patients because if therapy is to be effective, the therapeutic process must matter to the patient. "

Cheryl Mattingly

Professional Reasoning in Practice

BARBARA A. BOYT SCHELL

Learning Objectives

1. Describe important aspects of reasoning in occupational therapy practice
2. Identify the different facets of professional reasoning based on personal reflection, practitioners' descriptions, and case studies.
3. Describe the process of developing expertise and discuss characteristic reasoning processes along a continuum of expertise.

INTRODUCTION

Professional reasoning is the process that practitioners use to plan, direct, perform, and reflect on client care. It is typically performed quickly because the practitioner has to act on that reasoning right away. It is a complex and multifaceted process, and it has been called by several different names. In the past, many authors referred to it as ***clinical reasoning*** (Mattingly & Fleming, 1994; Rogers, 1983; Schell, 2003), but more recently, terms such as ***professional reasoning*** (Schell & Schell, 2008) and *therapeutic reasoning* (Kielhofner & Forsyth, 2002) have surfaced in an attempt to find a word that is not so closely aligned with medicine, since occupational therapy practices not only in medical settings, but in many educational and community settings as well. When using these labels, authors are talking about how therapists *actually think* when they actually are engaged in practice. This requires **metacognitive** analysis or, in simple terms, *thinking about thinking.* This is important because newcomers to the field might incorrectly understand professional reasoning as something that practitioners "choose to do" or confuse it with the many occupational therapy intervention theories. It is neither of those things. Whenever you are thinking about or doing occupational therapy for an identified individual or group, you are engaged in professional reasoning. It is not a question of whether you are doing it, only a question of how well. Furthermore, many practice theories are discussed throughout this text that will inform your reasoning and help you to think about your clients. However, the theories about reasoning that are discussed in this chapter are theories about how you as an occupational

therapy practitioner are likely to think as you engage in therapy. Thus, the focus is on the therapist, not on the client, although obviously, therapists do this thinking in the service of client care. Keep in mind these important distinctions as you become mindful of your own reasoning processes.

This chapter examines professional reasoning from several perspectives. To help you see real examples of the material discussed, the following Case Study, which is adapted, with name changes, from an actual situation, provides an example of an encounter between an occupational therapist, Terry, and her client, Mrs. Munro. Read this case study before continuing with the text, paying special attention to the different kinds of issues and problems that the occupational therapy practitioner has to address. Then keep referring back to it as you read about the nature of professional reasoning.

CASE STUDY: *Terry and Mrs. Munro: Determining Appropriate Recommendations*

Terry, an occupational therapist, goes up to a client's room in the neurology unit of a regional medical center. Along the way, she shares her thoughts with Barb, a researcher who is observing Terry's practice. Terry fills Barb in on the client they are about to see. The client, Mrs. Munro, is a widow who lives alone in a house in town. A couple of days earlier, she suffered a stroke—a right cerebrovascular accident—and was brought by a neighbor to the hospital. Mrs. Munro has made a rapid recovery and demonstrates good return of her motor skills. She still has some left-side weakness and incoordination, along with some cognitive problems. She is a delightful, pleasant older woman and is anxious to return home.

Terry is seeing this client for the third time, and her primary concern is to assess whether Mrs. Munro has any cognitive residual effects from her stroke that would put her at serious risk if she returned home alone. Terry plans to do some more in-depth activities of daily living with Mrs. Munro to see how well she demonstrates safety awareness. Terry thinks that she will probably have Mrs. Munro get out of bed, obtain her clothing and hygiene supplies, perform her morning hygiene routines at the sink, and then get dressed. Terry wants to see the degree to which Mrs. Munro is spontaneously able to manage these tasks as well has how good her judgment appears to be. Terry's thought is that if she can engage Mrs. Munro in several multistep activities that also require her to perform in different positions, Terry should be able to detect any cognitive and motor problems that pose a serious safety threat.

When Terry arrives at the room, she greets Mrs. Munro, who says, "I am so excited. The doctor says I can go home tomorrow."

Terry turns to Barb and raises her eyebrows as if to say, "I told you so." On the way to the room, Terry had told Barb that she was worried that the physician who was managing Mrs. Munro's case tended to think that as soon as clients could physically get up, they could go home. Terry went on to defend the physician by saying that in today's cost-conscious environment, doctors were under a lot of pressure not to keep clients in the hospital.

As Terry converses with Mrs. Munro about generalities, she notices that Mrs. Munro is already dressed in her housecoat. When she talks to Mrs. Munro about doing some self-care activities, it becomes apparent that Mrs. Munro has already completed her bathing and dressing routines, with help from a nurse. When Terry suggests that she perhaps brush her teeth and comb her hair, Mrs. Munro is happy to get up out of bed but notes that her neighbor never did bring in her dentures. Mrs. Munro sits on the edge of the bed and, after a reminder from Terry, puts on her slippers. She then stands and walks to the nearby sink, finds her comb, and combs her hair. While she is doing this, Terry looks around for some other ideas about what to do, since Mrs. Munro has already completed the self-care tasks Terry had planned to do with her.

Terry's eyes light on some wilted flowers by the bed. She suggests to Mrs. Munro that she might want to dispose of the flowers and clean the vase so that it will be ready to pack when it is time to go home. Mrs. Munro agrees and proceeds to walk somewhat unsteadily over to the vase. Picking it up, she carries it to the sink, where she pulls out the dead flowers. Terry follows her, staying slightly behind and within reach of Mrs. Munro. When Mrs. Munro stops after removing the flowers, Terry suggests that she rinse out the vase, which she does. She then dries it and returns the vase to the bedside table. Terry reminds her to throw out the dead flowers. While Mrs. Munro does this, they talk some more about her plans to return home.

Mrs. Munro tells Terry that she has lived in her home for 40 years, and even though her husband died over 10 years ago, she still feels his presence there. He used to love her cooking, and she still cooks three meals a day for herself. Mrs. Munro starts to cry when they talk about cooking but then cheers up. Terry tells her that it might be safer if she had someone around the house for a few weeks, until she recovers a bit more from her stroke. Mrs. Munro thinks that she can get some help from her neighbor. Terry says she is also going to suggest some home-care therapy, just to make sure Mrs. Munro is safe in the kitchen, bathroom, and so on, noting, "We sure don't want to see you have a bad fall just when you are doing so well after your stroke."

Continued

CASE STUDY: *Terry and Mrs. Munro:*
Determining Appropriate Recommendations   *Continued*

After reviewing some coordination exercises for Mrs. Munro's left hand, Terry says good-bye. Terry and Barb leave the room. Terry stops at the nurses' station to note in the chart that Mrs. Munro demonstrated good safety awareness in familiar tasks at her bedside but did require cueing to complete multistep tasks. Terry also notes some motor instability in task performance during ambulation. Terry recommends a referral to a home health occupational therapy practitioner "to assess safety and equipment needs during bathroom activities, meal preparation, and routine homemaking tasks." Terry comments to Barb, as they walk off the unit, that she thinks Mrs. Munro did pretty well, but Terry remains concerned about the risks once Mrs. Munro goes home, particularly when she is tired. Terry wants someone to monitor Mrs. Munro in a familiar setting to see whether she handles her daily routines adequately. Terry would really like to see Mrs. Munro go to a

rehab center, but the client has no insurance funding to support that. Terry believes that she might at least be able to get some home care, because there are a few programs around that provide some services to indigent elderly. Staying in her own home seems to be Mrs. Munro's major goal, and Terry is going to do what she can to try to help her attain that goal. Terry will catch up with the social worker later to discuss the need for Mrs. Munro to have good support from any neighbors, friends, or relatives.

Questions and Exercises

1. How did Terry develop her concerns about Mrs. Munro?
2. How did Terry know what to do when her initial plans did not work out?
3. What factors seem to guide Terry's recommendations at the end?

REASONING IN PRACTICE: A WHOLE-BODY PROCESS

With the case study in mind, let's explore the nature of reasoning during practice. Perhaps one of the first things to note is that professional reasoning is a *whole-body* process. That is one reason why it is a different experience to read a case study than to be the practitioner in the situation. Some professional reasoning involves straightforward thinking processes that the practitioner can easily describe. Examples include assessing occupational performance, such as daily living skills and work behaviors. Occupational therapy practitioners use their observations and theoretical knowledge to identify relevant client factors that contribute to occupational performance problems. Practitioners also attend to the contextual factors that affect performance. For instance, Terry was able to describe her concerns about Mrs. Munro's safety in returning home. In particular, Terry was addressing self-care and homemaking activities. She had analyzed relevant contextual factors about the home setting and Mrs. Munro's social and financial situation. Terry had identified some impairments in cognition and motor control that were affecting her client's occupational performance skills. This was all information that Terry could readily share with Barb. However, there was more knowledge from the therapy session that Terry either did not or could not put into words.

Part of Terry's professional reasoning involved body-based knowledge that she gained from her senses. For instance, Terry used her sense of touch to feel the muscle tension (or lack of tension) in Mrs. Munro's affected arm when she was doing an activity. During her evaluation, Terry did some quick stretches to Mrs. Munro's elbow and wrist to determine whether she could feel evidence of spasticity, an abnormal reflex response that is commonly found in individuals who are recovering from a stroke. When Mrs. Munro stood up, Terry carefully gauged the distance she stood from Mrs. Munro, because Mrs. Munro was at some risk of falling. Terry was careful to stand not so close that she crowded or overprotected Mrs. Munro but close enough to protect her should she lose her balance. While close to Mrs. Munro, Terry could smell her, gaining a quick sense of possible hygiene or continence problems. Terry used her voice quality to display encouragement and support. Terry watched and listened carefully for clues about the nature of Mrs. Munro's emotional state. In particular, she watched facial expressions and listened for evidence of fear or insecurity during Mrs. Munro's performance of activities. All of these sensations contributed to an image of Mrs. Munro that influenced Terry's practice.

There are other aspects of reasoning during therapy that are even harder to describe. Fleming (1994a) described this as "knowing more than we can tell" (p. 24). She explained that much of the profession's knowledge is practical knowledge, which is "seldom discussed and rarely described" (p. 25). This tacit knowledge, combined with the rich sensory aspects of actual practice, helps to explain why reading about therapy and doing therapy are such different experiences. In fact, recent work (Harris, 2005) suggests that each therapist's individual bodily differences and preferences may subtly shape therapy, in that some therapists might avoid situations that they find physically uncomfortable (e.g., if they are intolerant of

certain smells) and others might engage in therapy practices that they themselves find comforting (e.g., applying deep pressure, much like what one gets when being hugged). Hooper (1997, 2007) has also noted the importance of how our own values, beliefs, and assumptions underpin each practitioner's grasp of the therapy process. So keep in mind that therapy always happens in the real world with real people, and you will see variations because each therapist is different.

THEORY AND PRACTICE

There has been a long-standing discussion in many professions about the role of theory in professional practice (Kessels & Korthagen, 1996). Theories help practitioners to make decisions, although Cohn (1989) noted that the problems of practice rarely present themselves in the straightforward manner described in textbook theories. Professional reasoning involves the naming and framing of problems on the basis of a personal understanding of the client's situation (Schön, 1983). In problem identification and problem solution, practitioners blend theories with their own personal and practice experiences to guide their actions. Theoretical knowledge helps the practitioner to avoid unjustified assumptions or the use of ineffective therapy techniques and to reflect on how his or her own experiences in therapy are similar to or different from theoretical understandings (Parham, 1987). In Chapter 42, you will find more information about how theories inform practice. The point here is that although practice can (and should) be informed by theories, it is ultimately a result of how each therapist interprets each therapy situation and then acts on that understanding.

COGNITIVE PROCESSES UNDERLYING PROFESSIONAL REASONING

In the case study, Terry had to remember, obtain, and manage a great deal of information quickly to provide effective and efficient intervention. How did she do it? Research findings from the field of cognitive psychology help to explain how practitioners think and how experience combined with reflection fosters increasing expertise. Individuals receive, store, and organize information in *frames* or *scripts,* which are complex representations of phenomena (Bruning, Schraw, & Ronning, 1999; Carr & Shotwell, 2007). This process involves both working memory and long-term memory. Working memory can hold very few thoughts at a time, which is one reason that one sometimes has to look at the phone book two or three times in order to correctly recall a number one is dialing. Similarly, students and new practitioners find it challenging to try to keep all the important considerations in mind

when dealing with a client. Practitioners with extensive experience have this information organized and stored in their long-term memories and thus do not have to actively juggle all the details. For example, in school, Terry probably learned many of the common problems associated with someone who has had a stroke. She also has seen perhaps 100 people with strokes over the past several years. She has built up a general representation in her mind of what to expect when she receives a referral for someone who has had a stroke. She anticipates that many of these individuals will have thick medical charts, because they almost always have prior medical problems, such as diabetes and high blood pressure. She will not be surprised if the person is overweight. She expects to see impairments in cognition that often affect the person's ability to do everyday tasks, such as dressing, cooking, and driving. As part of her frame, Terry has built-in mental rules that help her to categorize and detect differences. For instance, although she knows that many people who have strokes have movement impairments, she knows that not all do. Furthermore, when movement is impaired, she expects individuals with a left cerebrovascular accident (CVA) to have right-side weakness and those with a right CVA to have left-side weakness. Additionally, she knows that a person's social support system is critical for promoting an adaptive response to disability. She may use certain cues, such as the presence or absence of frequent family visits, to prompt her to categorize a family as supportive or nonsupportive.

In addition to framing or "chunking" information, Terry also creates and uses scripts or procedural rules that guide her thinking (Bruning et al., 1999; Carr & Shotwell, 2007). Just as her mental frames help her to organize and retrieve her knowledge about common aspects of stroke, scripts help her to organize common occurrences or events. For instance, she understands that her role involves responding to the referral by seeing the client, writing her findings on the correct form, providing interventions, communicating verbally with the other team members, and developing discharge plans. Terry likely has scripts about the implications for clients with supportive families and those without. In her experience, a supportive family cares for its family member at home, regardless of the family's financial resources. Alternatively, clients with little family support are more likely to face institutional care. Again, these scripts are formed by Terry's observations and experiences over time and serve the purpose of helping her to anticipate likely events.

The mind appears to use frames and scripts to support effective processing of information by providing efficient mental frameworks for handling complex information. Each person individually constructs them. It is no surprise that students and new practitioners often struggle to retain and effectively use their therapy knowledge. It takes time and repetition of experiences to develop effective reasoning based on efficient storage in long-term memory allow-

ing for targeted use of short-term memory as therapy happens. Important aspects of the process are as follows (Bruning et al., 1999; Roberts, 1996; Robertson, 1996):

◆ *Cue acquisition:* Searching for the helpful and targeted information through observation and questioning.
◆ *Pattern recognition:* Noticing similarities and differences among situations.
◆ *Limiting the problem space:* Using patterns to help focus cue acquisition and knowledge application on the most fruitful areas.
◆ *Problem formulation:* Developing an explanation of what is going on, why it is going on, and what a better situation or outcome might be.
◆ *Problem solution:* Identifying courses of action based on the problem formulation.

These cognitive processes are interactive and rarely occur in a linear fashion. Rather, the mind jumps around between the information at hand and that which has been stored up from prior learning while attempting to make sense of the situation.

ASPECTS OF PROFESSIONAL REASONING

Although there appear to be common processes underlying reasoning in practice, the focus of that mental activity appears to vary with the demands of the problems to be addressed. Fleming (1991) was the first within occupational therapy to describe how occupational therapists seemed to use different thinking approaches, depending on the nature of the clinical problem they were addressing. She referred to this process as the "therapist with the three-track mind" (p. 1007). Since that time, others have examined the different aspects of occupational therapy professional reasoning. The vast majority of this research has been done with occupational therapists, although at least one case study (Lyons & Crepeau, 2001) suggests there is some application for occupational therapy assistants as well. These aspects of professional reasoning are listed in Table 32.1, along with the typical focus and clues for recognizing when that sort of reasoning is occurring.

Scientific Reasoning

Scientific reasoning is used to understand the condition that is affecting an individual and to decide on interventions that are in the client's best interest. It is a logical process that parallels scientific inquiry. Forms of scientific reasoning that are described in occupational therapy are diagnostic reasoning (Rogers & Holm, 1991) and procedural reasoning (Fleming, 1991, 1994b) in addition to the general use of hypothetical-deductive reasoning (Tomlin, 2008). Scientific reasoning is also referred to as treatment

planning (Pelland, 1987), in which the therapist uses selected theories both to identify problems and to guide decision making.

Diagnostic reasoning is concerned with clinical problem sensing and problem definition. The process starts in advance of seeing a client. Occupational therapy practitioners, because of their domains of concern, look primarily for occupational performance problems. Furthermore, the nature of the problems they expect to find is influenced by the information in the requests for services. Some of Terry's diagnostic reasoning, described earlier, included information about the typical symptoms associated with having a stroke.

Procedural reasoning occurs when practitioners are "thinking about the disease or disability and deciding which intervention activities (procedures) they might employ to remediate the person's functional performance problems" (Fleming, 1991, p. 1008). This may involve an interview, an observation of the person engaged in a task, or formal evaluations using standardized measures. Although one hopes that procedural reasoning is science-based, Tomlin makes the important observation that procedural reasoning can become an unquestioned implementation of therapy protocols, in which case it becomes less scientific in nature (Tomlin, 2008). That is why there is such an emphasis on evidence-based practice, which challenges the practitioner to routinely evaluate customary therapy approaches based on of the best information currently available (Holm, 2001; Law, 2002; Tickle-Degnen, 1998).

In the case study, Terry used a combination of interview and observation, both of which were guided by her working hypothesis that Mrs. Munro had cognitive problems that might affect her safe performance at home. She was likely operating on the basis of her understanding of cognitive theories (such as those described in Chapter 57), as well as her own experience with similar clients. As intervention begins, more data are collected, and the occupational therapy practitioner gains a sharper clinical image. This clinical image is the result of the interplay between what the occupational therapy practitioner expects to see (such as the usual course of the disease) and the client's actual performance. In the case study, there was congruence between Mrs. Munro's abilities and problems in performing activities of daily living and Terry's expectations of someone making a good recovery from a stroke.

Mattingly (1994a) made the point that occupational therapists have a "two-body practice" (p. 37). By that, she meant that occupational therapy practitioners view a person in two ways: the body as a machine, in which parts may be broken, and the person as a life, filled with personal meanings and hopes. Much of the procedural reasoning in occupational therapy addresses issues related to the body as machine. The next form of reasoning, narrative reasoning, provides the occupational therapy practitioner with a way to understand a person's illness experience.

TABLE 32.1   DIFFERENT ASPECTS OF REASONING IN OCCUPATIONAL THERAPY

Aspect of Reasoning	Description and Focus	Clues for Recognizing in Therapist Discussions
Scientific reasoning	Reasoning involving the use of applied logical and scientific methods, such as hypothesis testing, pattern recognition, theory-based decision making and statistical evidence.	Impersonal, focused on the diagnosis, condition, guiding theory, evidence from research or what "typically" happens with clients like the one being considered.
Diagnostic reasoning	Investigative reasoning and analysis of cause or nature of conditions requiring occupational therapy intervention. Can be considered one component of scientific reasoning.	Uses both personal and impersonal information. Therapists attempt to explain why client is experiencing problems using a blend of science-based and client-based information.
Procedural reasoning	Reasoning in which therapist considers and uses intervention routines for identified conditions. May be science-based or may reflect the habits and culture of the intervention setting.	Characterized by therapist using therapy regimes or routines thought to be effective with problems identified and that are typically used with clients in that setting. Tends to be more impersonal and diagnostically driven.
Narrative reasoning	Reasoning process used to make sense of people's particular circumstances, prospectively imagine the effect of illness, disability, or occupational performance problems on their daily lives, and create a collaborative story that is enacted with clients and families through intervention.	Personal, focused on the client, including past, present, and anticipated future. Involves an appreciation of client culture as the basis for understanding client narrative. Relates to the "so what" of the condition for the person's life.
Pragmatic reasoning	Practical reasoning which is used to fit therapy possibilities into the current realities of service delivery, such as scheduling options, payment for services, equipment availability, therapists' skills, management directives, and the personal situation of the therapist.	Generally not focused on client or client's condition, but rather on all the physical and social "stuff" that surrounds the therapy encounter, as well as the therapist's internal sense of what he or she is capable of and has the time and energy to complete.
Ethical reasoning	Reasoning directed toward analyzing an ethical dilemma, generating alternative solutions, and determining actions to be taken. Systematic approach to moral conflict.	Tension is often evident as therapist attempts to determine what is the "right" thing to do, particularly when faced with dilemmas in therapy, competing principles, risks, and benefits.
Interactive reasoning	Thinking directed toward building positive interpersonal relationships with clients, permitting collaborative problem identification and problem solving.	Therapist is concerned with what client likes or does not like. Use of praise, empathetic comments, and nonverbal behaviors to encourage and support client's cooperation.
Conditional reasoning	A blending of all forms of reasoning for the purposes of flexibly responding to changing conditions or predicting possible client futures.	Typically found with more experienced therapists who can "see" multiple futures, based on therapists past experiences and current information.

Used with permission from Schell & Schell (Eds.), (2008), and based on writings by Tomlin, Hamilton, Schell, Kanny, and Slater in Schell & Schell (2008); Rogers & Holm (1991); and Mattingly & Fleming (1994).

Narrative Reasoning

Understanding the meaning that a disease, illness, or disability has to an individual is a task that goes beyond the scientific understanding of disease processes and organ systems. Rather, it requires that practitioners find a way to understand the meaning of this experience from the client's perspective. Mattingly (1994b) suggested that practitioners do this through a form of reasoning called narrative reasoning. Narrative reasoning is so named because it involves thinking in story form. It is not uncommon for an occupational therapy practitioner who is preparing to substitute for another with a client to ask the other practitioner, "So what is the client's story?" As Kielhofner (1997) noted, narrative reasoning "becomes particularly important for considering how the person's disrupted life story can be constituted or reconstituted" (p. 316). Box 32.1 explains how narrative reasoning relates to scientific reasoning.

In the case study, part of Terry's reasoning was concerned with making decisions in light of what was important to Mrs. Munro. This process of collaboration and empathy has been described as "building a communal horizon of understanding" (Clark, Ennevor, & Richardson, 1996, p. 376). Terry gained understanding by listening attentively to Mrs. Munro's stories about her husband and how he loved her cooking. It is apparent from this session that Mrs. Munro's home is more than just a house. It is the place in which she lived with her husband, where he died, and where she still felt his presence. Part of Mrs. Munro's story is that going home is going back to her husband. If this stroke were to prevent that, Mrs. Munro would lose more than her independence; she would lose symbolic connections to her husband. Although a logical case might be made that Mrs. Munro should start considering a more supportive living environment, Terry understands that for Mrs. Munro, this would not be an acceptable ending. Consequently, Terry worked hard to obtain the support systems that would be necessary for Mrs. Munro to function in her chosen environment, where she will continue her life story.

Often, occupational therapy practitioners work with individuals whose life stories are so severely disrupted that they cannot imagine what their future will look like. Mattingly (1994b) believes that in these situations, skillful practitioners help their clients to invent new life stories. To some degree, these stories become visible as the occupational therapy practitioner and the client develop goals together. The use of life stories is also apparent when activities are selected for both their healing potential and their particular significance to the person. To do this, one must first solicit occupational stories from the individual (Clark et al., 1996). With an understanding of clients' past occupational stories, practitioners can help individuals to create new stories and new futures for themselves. If Mrs. Munro's symptoms were more severe and she was in a more extended therapy process, Terry might explore Mrs. Munro's interest in cooking as an activity that she liked and that would offer many therapeutic opportunities. Further, Mrs. Munro might find that she could express her pleasure in cooking for others by making special treats, first for other clients and then perhaps for neighbors in exchange for their help with chores. During this process, Mrs. Munro would not only be regaining coordination and dexterity, she would also be regaining her sense of self as a productive person. This narrative aspect of clinical reasoning, which ultimately focuses on the person as an occupational being, provides a link between the founding values of the profession and current practice demands (Gray, 1998).

Pragmatic Reasoning

Pragmatic reasoning is yet another strand of reasoning that goes beyond the practitioner-client relationship and addresses the world in which therapy occurs (Schell, 2008; Schell & Cervero, 1993 This world is considered from two perspectives: the practice context and the personal context. Because reasoning during therapy is a practical activity, a number of everyday issues have been identified over the years that affect the therapy process. These include resources for intervention, organizational

BOX 32.1

SCIENTIFIC AND NARRATIVE THINKING: TWO SIDES OF A COIN

Narrative thinking deals in subjective, personalized particulars and specifics of lived experience, human intention, and action that connects events across time and defines possibilities. The use of personal experience and concern for the human condition defines its characteristic subjective and personalized position. A frequent and inaccurate assumption is that scientific thinking and narrative thinking are opposed to each other or that one is has more validity or utility than the other does. . . . We can illustrate this by examining a coin. We notice that each side contributes different aspects to the coin that we label the "head" and the "tail." Regardless of the side showing, we recognize the object as a coin. Similarly, when using a coin to make a purchase, it does not matter how we insert the coin in the vending slot or hand it to the cashier. The coin's validity is apparent regardless of which side of the coin shows. . . . Together scientific and narrative thinking and reasoning help us form perspectives on a single reality and truth, just as the head and tail of a coin show different sides of one coin.

Hamilton (2008).

culture, power relationships among team members, re-imbursement practices, and practice trends in the profession (Barris, 1987; Howard, 1991; Neuhaus, 1988; Rogers & Holm, 1991). Studies examining clinical reasoning have confirmed that occupational therapy practitioners both actively consider and are influenced by their practice contexts (Creighton, Dijkers, Bennett, & Brown, 1995; Schell, 1994; Strong, Gilbert, Cassidy, & Bennett, 1995). An example of pragmatic reasoning in the case study was Terry's use of immediate resources (the flower vase) in Mrs. Munro's room as a therapy tool. Although Terry had thought of appropriate activities related to self-care, she had to identify practical alternatives quickly when it turned out that Mrs. Munro was already dressed. Practical constraints for Terry included (1) the time it would take to move Mrs. Munro to the clinic, where there might be more resources; (2) the need to get the required information on that day, since Mrs. Munro was going home; and (3) the physical constraints of what was available within the room. Terry's invention of a feasible alternative was a product of both her therapeutic imagination and the cues that were provided within her practice setting.

Terry's attention to the influence of team members demonstrates pragmatic reasoning directed to interpersonal and group issues. She knew that the physician had the power to make discharge decisions. She was aware of the pressures on the physician by third-party payers to discharge clients as quickly as possible. Practice requires that practitioners reason about negotiating their clients' interests within the practice culture.

The practitioner's personal situation also is part of the pragmatic reasoning process. A person's clinical competencies, preferences, commitment to the profession, and life role demands outside of work all affect the therapy choices that are considered and thus enter into the reasoning process. For instance, if a practitioner does not feel safe helping a client stand or transfer to a bed, the therapist is more likely to use tabletop activities, in which the client can participate from a wheelchair. Another occupational therapy practitioner might feel uncomfortable interacting with individuals who have depression and therefore might be quick to suggest that such clients are not motivated for therapy. A practitioner who has a young family to go home to might opt not to schedule clients late in the day, so as to get home as early as possible. These simple personal issues result in clinical decisions that affect the scope and timing of therapy services. Hooper (1997, 2008) suggested that fundamental issues, such as a practitioner's values and general worldview, strongly affect the way in which an individual constructs his or her reasoning. Such worldviews play an important role in the next kind of reasoning: ethical reasoning.

Ethical Reasoning

All of the forms of reasoning that have been described so far help the practitioner to respond to the following ques-

tions: What is this person's current occupational situation? What can be done to enhance the person's situation? Ethical reasoning goes one step further and asks: What should be done? Rogers (1983) framed these three questions (here paraphrased) in her Eleanor Clark Slagle Lecture and went on to state, "The clinical reasoning process terminates in an ethical decision, rather than a scientific one, and the ethical nature of the goal of clinical reasoning projects itself over the entire sequence" (p. 602). In the case study, Terry's ethical dilemma is to understand Mrs. Munro's personal wishes and to honor them when developing a therapy plan that realistically addresses Mrs. Munro's limitations. This can be particularly challenging when the pressures of financial realities (such as Mrs. Munro's lack of insurance) affect available options. A number of occupational therapy authors have addressed the ethical aspect of professional reasoning (Fondiller, Rosage, & Neuhaus; 1990; Howard, 1991; Neuhaus, 1988; Peloquin, 1993), and Chapter 28 of this text is devoted to the issue of the ethics of the profession. The purpose here is to introduce ethical reasoning as yet another of the components of professional reasoning in occupational therapy.

Interactive Reasoning

The provision of therapy is inherently a communicative process (Schwartzberg, 2002). In occupational therapy, practitioners must gain the trust of their clients and of people who are important in the clients' world. This is because occupational therapy involves "doing with" as opposed to "doing to" clients (Mattingly & Fleming, 1994, p. 178). A therapist gains this trust by entering the client's life world (Crepeau, 1991) and by using a number of interpersonal strategies that are designed to motivate clients, such as those discussed in Chapter 33. Once they are in the client's life world, occupational therapy practitioners can better understand how to help the individual resolve performance problems.

It is likely that some reasoning focused on interaction is conscious, as when a practitioner remembers that "I need to be sure to praise the client often, because he gets discouraged so easily." Other interpersonal acts might be quite automatic, such as when a therapist touches a person's arm to convey sympathy. It is sometimes easiest to detect the importance of effective interactive reasoning when the therapist makes a mistake or gets an unexpected reaction and is forced to regroup and rebuild the therapy relationship.

PROFESSIONAL REASONING: A PROCESS OF SYNTHESIS

The preceding section described the aspects of professional reasoning separately to illustrate the different parts of the process. Table 32.2 provides a summary of the kinds of

TABLE 32.2 ASPECTS AND EXAMPLES OF THE CLINICAL REASONING PROCESS

Primary Clinical Reasoning Concerns

What are the person's occupational performance concerns?

What are the person's occupational performance status and potential?

What will be done to improve occupational performance?

How are effective are interventions?

When and how should interventions stop?

Scientific	Narrative	Pragmatic	Ethical	Interactive
Used to understand the nature of the condition	Used to understand the meaning of the condition to the person	Used to understand the practical issues affecting clinical action	Used to choose morally defensible actions, given competing interests	Used to develop and promote positive interpersonal relationships with the client
What is the nature of the illness, injury, or development problem?	What is this person's life story?	Who referred this person and why?	What are the benefits and risks to the person related to service provision and do the benefits warrant the risks?	How can I best relate to this person?
What are the common disabilities resulting from this condition?	What is the nature of this person as an occupational being?	Who is paying for services, and what are the expectations?	In the face of limited time and resources, what is the fairest way to prioritize care?	How can I put this person at ease?
What are the typical impairments associated with this condition?	How has the health condition affected the person's life story or ability to continue his or her life story?	What family or caregiver resources are there to support intervention?	How can I balance the goals of the person receiving services with those of the caregiver when they don't agree?	What is the best way for me to encourage this person?
What are the typical contextual factors that affect performance?	What occupational activities are most important to this person?	What are the expectations of my supervisor and workplace?	To what degree should I customize documentation of services to improve reimbursement?	What nonverbal strategies should I use in this situation?
What theories and research are available to guide assessment and intervention?	What occupational activities are both meaningful to this person and useful for meeting therapy goals?	How much time is there to see this person? What therapy space and equipment are available?	What should I do when other members of the treatment team are operating in ways that I feel conflict with the goals of the person receiving services?	Where should I place myself relative to this person so that I support him or her but do not "invade" the person?
What intervention protocols are applicable to this person's condition?		What are my practice competencies?		What cultural factors do I need to consider as I engage with the person?

questions that practitioners seek to answer with the different aspects of professional reasoning. However, these facets of reasoning are not separate or parallel processes; rather, the opposite appears to be the case. Virtually all the research about reasoning in practice suggests that these different forms interact with each other.

Reasoning to Solve Problems

Scientific, narrative, pragmatic, ethical, and interactive reasoning processes are intertwined throughout the therapy process. Indeed, each perspective informs the other. In the case study, Terry's understanding of medical science helped her to know what might be potential impairments and performance problems, but her narrative reasoning helped her to understand the importance for Mrs. Munro of returning home. Put together, these two forms of reasoning help Terry to reach an unspoken understanding that there would be a high risk for depression (which could worsen her client's medical condition) if Mrs. Munro did not return to her home, which means so much to her. Furthermore, the practical constraints associated with the setting and Mrs. Munro's reimbursement prompted Terry to reason about the ethics of referring Mrs. Munro to a rehabilitation center (which she could not afford), of allowing her to return home alone (where she might not be safe), and finally of allowing her to return home with the support of home health care and neighbors.

Conditional Process

Not only must practitioners blend different aspects of reasoning in order to interact effectively with their clients, but they must also flexibly modify interventions in response to changing conditions. Terry showed her flexibility by inventing an activity with the flower vase when her plan to work with Mrs. Munro on bathing and dressing did not pan out. Creighton and colleagues (1995) noticed that occupational therapy practitioners preplanned interventions in a hierarchical manner. They observed that practitioners typically brought several sets of supplies to an intervention session. One set would be directed to the expected level of performance, the others to a stage higher and a stage lower than the expected performance. As an example, one practitioner, in preparation for a writing activity with a client who had a spinal cord injury, brought a short writing splint and unlined paper. This practitioner also brought a longer splint to provide wrist support (in case the client's hand control was worse than expected) and lined paper, which required more precision (in case the hand control was better than expected). This practitioner blended scientific and pragmatic concerns in a way that anticipated several possible situations that might occur.

On a larger scale, Fleming (1994c) described the ability of skilled occupational therapy practitioners to "form an image of future life possibilities for the person" (p. 234). The ability to form these images (or schemata, to use a cognitive terms) seems to require a blend of all the forms of clinical reasoning, along with sufficient clinical experience to have seen a variety of different outcomes with former clients. These images help practitioners to select therapeutic activities on a day-to-day basis. For instance, the writing activity for the client who had a spinal cord injury not only is a good activity for increasing coordination, but also presages occupations that will enable the client to regain control of his life through writing his own checks, signing his name on legal documents, and using various forms of technology for work and play. If this client were an accountant, these would be powerful images. Conversely, if the client were a professional athlete, the occupational therapy practitioner might have to create different activities to allow the client to develop a vision of himself as a future coach or teacher. The activities that are used in occupational therapy can help to meet specific short-term goals and shape long-term expectations. It is in this way that practitioners help individuals to reengage in their lives through the use of meaningful occupations.

ECOLOGICAL VIEW OF PROFESSIONAL REASONING

In Unit I, a number of chapters discussed how occupational performance is the result of a complex transaction among a person's inherent capacities, the person's prior experiences, and the demands of the performance context. Similarly, the professional reasoning process and the resulting therapy actions represent transactions that occur among the practitioner, the client, and the therapy context (Schell, Unsworth, & Schell, 2008) as illustrated in Figure 32.1.

The practitioner's reasoning is shaped by both personal and professional perspectives. Each practitioner brings to the therapy situation knowledge and skills that are grounded in life experiences, including personal characteristics such as physical capacities, personality, values, and beliefs. These form a *personal self.* These personal factors shape each person's perception and interpretation of all life activities and thus act as a lens through which each practitioner views all life events. Layered over or entwined with this personal self is the *professional self,* which includes the therapist's professional knowledge from education, experiences from prior clients, and beliefs about what is important to do in therapy, along with knowledge of specific technical skills and therapy routines available for use in the practice context. The personal and professional selves act in concert to respond to various problems of practice.

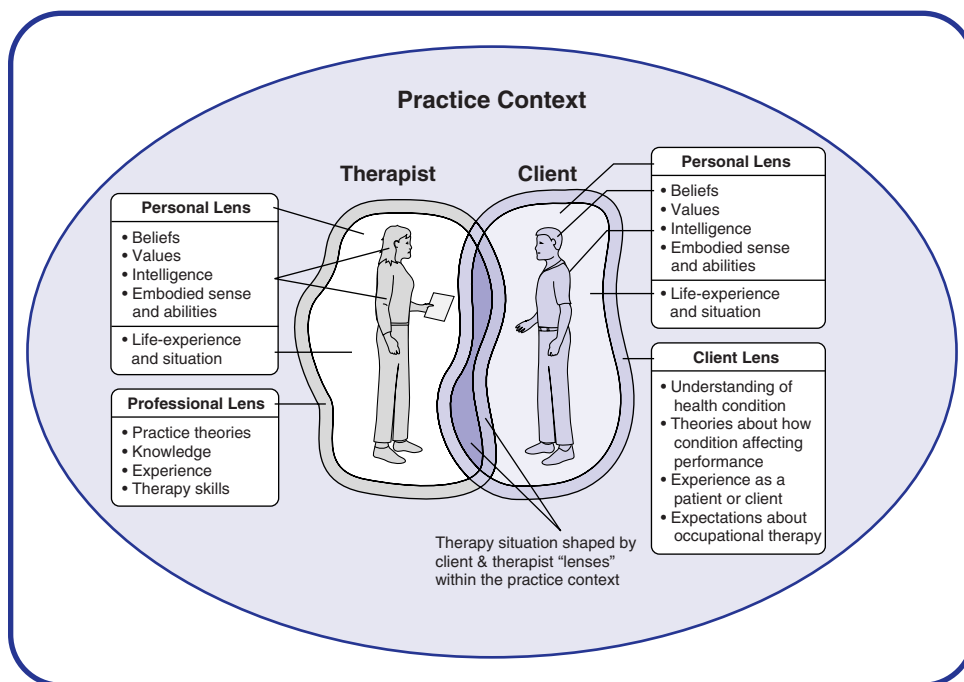
Similarly, the client comes to therapy with his or her own life experiences and personal characteristics, life


FIGURE 32.1 Schell's ecological model of professional reasoning. [Adapted from Schell, B. A. B., Unsworth, C., & Schell, J. (2008).]

situation, and performance problems that prompted the need for therapy. The client also comes with his or her own theories about what is causing performance problems and what to expect from the therapy process. The therapist and the client function within a community of practice that shapes the nature, scope, and trajectory of the therapy process.

DEVELOPING AND IMPROVING PROFESSIONAL REASONING

Understanding the complexity of professional reasoning helps students and practitioners alike to appreciate why it takes so long to truly become an excellent practitioner. Research shows that it typically takes a minimum of 10 years for individuals to gain expertise within a given field (Boshuizen & Schmidt, 2000). Although experience is necessary, experience alone is not sufficient to ensure advancement in clinical reasoning skills. Therapists must reflect on that experience in order to gain expertise.

Reflection in Practice

Schön (1983) proffered the term *reflective practitioner* to describe how experts think critically about their own experience. Reflection happens in two ways. First, practitioners "reflect-in-action" (p. 49). This involves the practitioner's ability to think in the midst of action and adapt to meet the demands of the situation. Reflection in action most often occurs when the usual approaches are not working. "Reflection-on-action" (p. 61) is the

term Schön uses for critical thinking that occurs after the fact. Reflection about practice, identifying what worked and what did not, and being open to alternative conceptions are necessary to support the learning associated with advancing expertise. The use of research evidence to support practice and the application of formal theories, along with systematic observation and data collection, can be invaluable aides to the reflection process (Gambrill, 2005; Tickle-Degnen, 2000).

Expertise Continuum

Although there is a growing body of evidence about the nature of professional reasoning in occupational therapy, there is still little empirical research that directly examines its development beyond entry level into the profession. Dreyfus and Dreyfus's (1986) conceptualization of professional expertise has been applied to occupational therapy (Slater & Cohn, 1991). This conceptualization, summarized in Table 32.3, describes changes in the reasoning of occupational therapists as they develop expertise. Although the changes that are listed in Table 32.3 are presented as a hierarchy tied to years of experience, it is important to recognize that development is dynamic and influenced by many factors beyond just the years of experience. Both professional and personal experiences, along with active reflection about those experiences, are critical to becoming an expert (Benner, 1984; Gambrill, 2005; Slater & Cohn, 1991). Furthermore, expertise is a function of how the person performs within a given context. Someone who demonstrates expertise at providing services in a school setting might be just minimally competent in a nursing

TABLE 32.3   PROFESSIONAL REASONING CONTINUUM AND CHARACTERISTICS

Category	Years of Reflective Practice	Characteristics
Novice	0	◆ No experience in situation of practice; depends on theory to guide practice ◆ Uses rule-based procedural reasoning to guide actions but does not recognize contextual cues; not skillful in adapting rules to fit situation ◆ Narrative reasoning is used to establish social relationships but does not significantly inform practice ◆ Pragmatic reasoning is stressed in terms of job survival skills ◆ Recognizes overt ethical issues
Advanced beginner	<1	◆ Begins to incorporate contextual information into rule-based thinking ◆ Recognizes differences between theoretical expectations and presenting problems ◆ Limited experience impedes recognition of patterns and identification of salient cues; does not prioritize well ◆ Gaining skill in pragmatic and narrative reasoning ◆ Begins to recognize more subtle ethical issues
Competent	3	◆ Automatically performs more therapeutic skills and attends to more issues ◆ Is able to develop communal horizon with people receiving service ◆ Is able to sort relevant data and prioritize intervention goals related to desired outcomes ◆ Planning is deliberate, efficient, and responsive to contextual issues ◆ Uses conditional reasoning to modify intervention but lacks flexibility of more advanced practitioners ◆ Recognizes ethical dilemmas posed by practice setting but may be less sensitive to justifiably different ethical responses
Proficient	5	◆ Perceives situations as wholes ◆ Reflects on expanded range of experiences, permitting more focused evaluation and more flexibility in intervention ◆ Creatively combines different diagnostic and procedural approaches ◆ More attentive to occupational stories and relevance for intervention ◆ More skillful in negotiating resources to meet patient/client needs ◆ Increased sophistication in recognizing situational nature of ethical reasoning
Expert	10	◆ Clinical reasoning becomes a quick intuitive process, which is deeply internalized and embedded in an extensive range of case experiences, permitting practice with less routine analysis, except when confronted with situations in which approach is not working ◆ Highly skillful use of occupational story making during intervention to promote long-term occupational performance satisfaction

Modified from Dreyfus and Dreyfus (1986) to include information from Benner (1984); Clark, Ennevor, and Richardson (1996); Creighton, Dijkers, Bennett, and Brown (1995); Mattingly and Fleming (1994); Slater and Cohn (1991); and Strong, Gilbert, Cassidy, and Bennett (1995).

home setting. Refer to Chapter 25 for a discussion of competence and practice context.

CONCLUSION

Professional reasoning is the process that practitioners use to plan, direct, perform, and reflect on client care. It is a whole-body and multisensory process that requires complex cognitive activity. Practitioners develop cognitive frames and scripts as they gain experience, forming the basis of professional knowledge and action. Professional reasoning is multifaceted and enables practitioners to understand client issues from different perspectives. Practitioners use the logical processes associated with scientific reasoning to understand the client's impairments, disabili-

ties, and performance contexts and to predict the impact these have on occupational performance. Narrative reasoning helps practitioners to appreciate the meaning of occupational performance limitations to the client, thus supporting client-centered care. Practitioners use pragmatic reasoning when they address the practical realities associated with service delivery. All of these forms of reasoning lead to an ethical reasoning process by which practitioners select the best therapy action to respond to the client's occupational performance needs. The process of professional reasoning involves a transaction among the practitioner's personal and professional perspectives, the client's perspectives, and the demands of the practice context. Expertise develops as the practitioner gains experience and reflects on that experience for deeper understanding.

PROVOCATIVE QUESTIONS

1. What are some of the personal factors in your life that you think will influence the way in which you practice occupational therapy?
2. How do you think you might deal with research evidence that is in conflict with your own experience or personal beliefs? What are some appropriate responses?

The Therapeutic Relationship

33

POLLIE PRICE

Learning Objectives

After reading this chapter, you will be able to:

1. Identify the phases of the therapeutic relationship and stages of the therapeutic process.
2. Describe strategies to establish a therapeutic relationship with clients.
3. Describe strategies to move a therapy process toward desired outcomes.

WHY IS THE THERAPEUTIC RELATIONSHIP IMPORTANT IN OCCUPATIONAL THERAPY?

All professionals who provide services enter into relationships of some sort with people seeking services. In some service fields, the relationship is secondary, superficial, and based on exchange of information. However, occupational therapy practitioners often meet people at points of significant transition, requiring more intimate exchanges. Practitioners may meet parents when they are first told that their 3-year-old child has autism, when a man wakes up in the intensive care unit to find that he has had a stroke and is paralyzed on one side of his body, when a woman arrives at a shelter with her two young children to take refuge from an abusive husband, or when a young adult has a confusing and frightening experience of schizophrenia. Occupational therapists who enter individuals' lives at such times are called on to quickly create therapeutic relationships that convey empathy and a consistent willingness to both "be there" and "do with" clients through a process that the clients did not bargain for and might not be able to work through alone (Lawlor, 2003; Peloquin, 1995).

In occupational therapy, therapeutic relationships are not just a by-product of working with human beings. Rather, the therapeutic relationship is the central aspect of the therapeutic process of occupational therapy and one catalyst for change (Devereaux, 1984; Peloquin, 1990; Price, 2003; Schwartzberg, 1993; Yerxa, 1967). Occupational therapists understand that to take action on their own behalf, clients need hope as well as professional guidance (Fleming, 1994). An individual's process of recovery and adaptation requires professional expertise but also an empathic partner who is willing to feel the individual's fear, uncertainty, or despair and to provide support, encouragement, and hope. The degree to which the occupational therapist is able to understand the fears, hopes, priorities, and desires of the client and family will influence collaborative goal setting,

intervention plans and activities, and the entire therapy process (Van Amburg, 1997).

> **The therapeutic relationship is the central aspect of the therapeutic process of occupational therapy and one catalyst for change.**

The relationship aspect of the therapy process has often been called "the art of practice." The process of establishing a relationship with another person is a creative and interdependent act and requires that two people come to understand, trust, and respect one another and create shared meanings about what the therapy process means for the person's life and future (Clark, 1993; Clark, Ennevor, & Richardson, 1996). The interactive qualities that enable two people to build a therapeutic relationship are not instinctive or automatic but require mutual willingness, vigilance, attention, and responsiveness (Tickle-Degnen, 2003). The interactive aspects of the therapeutic relationship require interpersonal and communicative skills that an occupational therapist can learn and develop through reflective practice. In a recent study, Gahnström-Strandqvist, Tham, Josephsson, and Borell (2000) called these skills "**empathic competence**" (p. 23), which is defined as the therapist's emotional ability to accurately perceive and respond to clients and their experiences in order to fine-tune the therapy process. The researchers provided empirical evidence that empathic competence is an important feature of professional competence and professional knowledge (Gahnström-Strandqvist et al., 2000). These interactive, interpersonal, and communication skills cannot be learned and applied in practice as a list of procedures and techniques; rather, therapeutic relationships emerge out of real care, from dynamic and responsive interactions, and from both tacit and explicit reasoning as the therapist and client work together toward a common desired outcome. Therefore, truly understanding and caring about clients and their experiences, hopes, and dreams are essential to this emotional aspect of practice and require a personal commitment to self-awareness, reflection, and development of interactive, interpersonal, and communication skills.

For a variety of reasons, occupational therapists frequently get "stuck" in their work with clients, and the therapeutic process stalls. At these stuck points, therapists must reflect on their approaches and determine how to improve them in order to move the therapy process forward or to work more effectively with subsequent clients (Spencer, Davidson, & White, 1996). Consequently, experienced therapists who have reflected on their processes are likely to have more highly developed interactive skills than are novice therapists (Mattingly & Fleming, 1994). Occupational therapy students and new practitioners are encouraged to focus on developing their interactive, interpersonal, and communicative skills as much as they would focus on developing their manual muscle testing skills (Neistadt, 1995).

The therapeutic relationship provides the foundation for collaborative partnerships to develop between clients and therapists. Two important predictors of rehabilitation outcomes are the respect and collaboration that develop between clients and their therapists (Law, 1998). Collaborative goal setting leads to shorter inpatient stays, better goal attainment, and increased client satisfaction (Neistadt, 1995). Occupational therapists feel most competent when both they and their clients are satisfied with the therapy outcomes they achieve (Gahnström-Strandqvist et al., 2000). By blending professional and empathic competence, therapists can help clients to envision a course of action that is both attainable and worth working toward (Gahnström-Strandqvist et al., 2000; Mattingly, 1994; Peloquin, 1990). Understanding that it is not enough to present clients with a set of procedures and techniques that will optimize physical, emotional, or medical outcomes, occupational therapists embark on a spiritual or existential journey with clients by collaborating and helping to create possibilities.

Collaboration and collaborative relationship have been used interchangeably in the literature and are closely related in meaning to "client-centered practice" (Law, Baptiste, & Mills, 1995). **Client-centered occupational therapy** has been described as a philosophy of service committed to "respect for and partnership with people receiving services" (Law et al., 1995, p. 253). **Collaboration** has been described as the process through which therapists and clients discuss priorities, set goals, and make decisions about intervention and postintervention options (Cipriani et al., 1999; Spencer, 1993) and work together in mutual effort toward goals (Neistadt, 1995). However, clients have different needs and desires related to the degree and type of collaboration in therapeutic relationships. Some clients want the therapist to be "the expert" in making clinical decisions, while others want to take the lead in their therapy process. When therapists meet clients' needs, clients experience positive relationships with their therapists and satisfaction with therapy outcomes (Cipriani et al., 1999).

HOW DO THERAPISTS AND CLIENTS DEVELOP A THERAPEUTIC RELATIONSHIP?

In occupational therapy, the therapeutic relationship requires a degree of intimacy that develops along a continuum depending on the nature of the individual's condition, the degree of disruption to his or her life and identity, the extent of recovery expected, and the length and complexity of the recovery and adaptation process, including the occupational therapy process. Several authors have theorized that the therapeutic relationship develops in phases and that the developing relationship both shapes and is shaped by the therapist and client's engagement in and experience of the therapy process (see Table 33.1) (Paddy,

TABLE 33.1 HOW THE THERAPEUTIC RELATIONSHIP INTERSECTS WITH THE THERAPEUTIC PROCESS

Phases of Relationship Development	Strategies	Stages of Therapeutic Process	Strategies
Phase 1: Develop rapport	◆ Honor the client's dignity. ◆ Demonstrate willingness to experience the client's grief, despair, and hope. ◆ Meet the client's desired level of intimacy.	**Stage 1: Being there and understanding the client**	◆ *Be with* socially. ◆ Ask about habits, roles, interests, priorities, and resources. ◆ Generate past and present narrative images of the client. ◆ Observe the client's responses, abilities, and adaptive style.
Phase 2: Establish trust	◆ Create trust by spending time, giving information, and ensuring client choice. ◆ Convey best practice options within an understanding of the client's priorities.	**Stage 2: Engaging the client in therapy**	◆ Get the client to self-appraise through doing, using a functional measurement scale, videotapes, and other clients to increase awareness. ◆ Offer meaningful options and explore possibilities. ◆ Explain the purpose of therapy activities.
Phase 3: Develop a collaborative partnership	◆ In the role of covenanter (Peloquin, 1990), share the difficult path to knowledge and competence.	**Stage 3: Working together**	◆ The therapist and client take on active and equal roles and effort. ◆ The therapist brings professional expertise; the client brings expertise about his or her own life. ◆ Support the client to set goals and make decisions about therapy activities. ◆ Convey trust in the client's abilities. ◆ Uncover and activate the client's resources and problem solving. ◆ Have the client perform to explore limitations and solutions.
Phase 4: Sustain a therapeutic relationship	◆ As trust and confidence deepen, therapeutic roles, strategies, and activities change. ◆ The client fluctuates between need for affiliation and need for autonomy.	**Stage 4: Enabling occupational performance**	◆ Pool resources and persevere in creating solutions. ◆ Point out disabilities and accomplishments. ◆ Adjust therapeutic strategies. ◆ Teach problem solving and convey confidence through taking risks; create opportunities to practice in real situations. ◆ Go with the client's time rhythm. ◆ Change roles from director to follower.
Phase 5: Relationship endures	◆ The relationship endures after therapy ends. ◆ The client is "held in mind" (Paddy et al., 2002); "they would always be there for you" (Mitchell, Price, & Ward, 2006).	**Stage 5: Outcomes**	◆ Clients reach *their* goals. ◆ Clients live fulfilling lives doing their occupations. ◆ Therapy results are satisfying to both client and therapist. ◆ The client has a sense of control and autonomy over managing his or her life.

Wright-Sinclair, & Smythe, 2002; Peloquin, 1993, 2003; Tickle-Degnen, 2002).

Phase One: Development of Rapport: Entering the Life World of Another

When developing rapport, the therapist and client exchange information in order to understand each other's desires and motives. To establish rapport, the therapist must honor the client's dignity or worthiness (Devereaux, 1984; Peloquin, 1990, 1995, 2003) and convey professional competence and empathy (Figure 33.1). "**Empathy**, in health care practice, is the enactment of the conviction that, empowered by someone else's willingness to understand, a person will gather courage" (Peloquin, 2003, p. 159). Becoming a part of a client's life requires a deep knowingness that comes from concern, openness, listening and responding, and relating as a fellow human being (Paddy et al., 2002; Peloquin, 1995). When therapists convey genuine interest in understanding the client's life world, the client may be more likely to embark in a collaborative and mutually created therapeutic process.
The occupational therapy process begins with an occupational profile, which consists of a formal interview with the client and/or important others (e.g., spouse, parent, teacher, caregiver), using, for example, the Canadian Occupational Performance Measure (Law et al., 1990), or the Occupational Performance History Interview (Kielhofner et al., 1997). These measures help occupational therapists begin to explore a client's life world, occupational history, and priorities.

In addition to using formal interview measures, therapists use informal narrative strategies, including storytelling (Clark, 1993; Jackson, 1998; Mattingly, 1994; 1998; Spencer, Krefting, & Mattingly, 1993). Enabling clients to tell stories about their lives and their hopes for the future is a skill therapists can develop (Clark, 1993; Mattingly, 1994, 1998). Therapists use several strategies to enable clients to tell and make stories, such as sharing personal experiences, talking about shared interests, and asking questions such as "What do you most look forward to resuming?" or "What would you be doing if you were home and feeling well? (Price-Lackey & Kennedy, unpublished data)." Such simple gestures convey humanity and offer clients an opportunity to tell therapists what they care about and may also allow the discovery or creation of adaptive strategies (Clark, Ennevor, & Larsen, 1996).

Phase Two: Establishing Trust

A therapist engenders trust by spending time with the client, giving undivided attention to the client, and eliciting and listening to stories. Conveying interest and verbalizing an understanding of the client's life world, fears, and priorities will provide a narrative context for considering and offering the best intervention options. A therapist demonstrates both professional and empathic competence when offering clients a choice of evidence-based options that address their priorities (Gahnström-Strandqvist et al., 2000; Peloquin, 1990, 2003). This blend of competencies creates the foundation for trust and confidence to be established between therapists and clients and will launch collaborative partnerships.

Phase Three: Developing a Collaborative Partnership

Based on a foundation of mutual respect and trust that is developed between clients and therapists in the first few interactions, a working alliance can then be developed (Tickle-Degnen, 2002). Therapist and client together discuss what is important to the client, identify desired outcomes, develop goals and therapy plans, and commit to work together toward those goals. The therapist and client discuss and make decisions about treatment options based on current research evidence (Cipriani et al., 1999;

FIGURE 33.1   Therapist listening to client to establish rapport.

Tickle-Degnen, 2002). As therapy begins, there may be a period of trial and error and a revision of plans, activities, and approaches (Mattingly & Fleming, 1994). The therapist may take on different roles, taking more of a lead at first and then hanging back to let clients explore their abilities, limitations, and potential solutions, all the while conveying to the client that the therapist will continue to be there for professional guidance, personal support and encouragement, and accurate feedback about the client's abilities and potential (Gahnström-Strandqvist et al., 2000; Guidetti & Tham, 2002). This "doing with" conveys the quality of being a "covenanter" who will be with the client until the client can do on his or her own (Peloquin, 1990). As trust deepens, the therapist may place increased demands on the client and let the client take more risks and possibly experience failure to help the client develop more awareness, problem solving, and effective solutions (Guidetti & Tham, 2002). The therapeutic relationship changes as a shared understanding of what is important and at stake grows. This increased understanding shapes the therapeutic process, enabling the therapist to fine-tune and individualize the therapy to address the outcomes in which the client is most invested (Crepeau, 1991). These developments strengthen the relationship as the client and therapist continually re-evaluate the therapy goals and therapy process until goals are reached and the formal relationship is dissolved.

The therapist and client continue to disclose important information through interactions that are interwoven within the actions of therapy, including storytelling and storymaking (Clark, 1993; Jackson, 1998; Mattingly, 1994). Through mutual engagement in the process of therapy and the creation of narrative stories, shared meaning is created between therapist and client about the relationship of the therapy to the client's goals for the future (Mattingly, 1991, 1994, 1998; Price, 2003). For example, one of the therapists in Gahnström-Strandqvist and colleagues' (2000) study encouraged her client to fix a dripping tap:

> I encouraged him to fix a dripping tap, which was so annoying to him. "If I were well, I would do it," he said. "But, you can still do this," I said, "do it now." He was very thorough and it took a long, long time, but he did it." (p. 21)

From a narrative standpoint, the therapy activity, fixing a dripping tap, was loaded with symbolic meaning. It conveyed the therapist's trust in the client's ability to complete the task competently and drew on the client's trust in the therapist's professional competence to choose a task that he was capable of doing. Finally, by picking a task that was essentially occupational in nature, the therapist provided an opportunity for the client to experience his "self" doing an old occupation in a new way.

Storytelling can help therapists to understand the meanings and motives underlying their clients' decisions,

actions, and inactions; storymaking can help therapists and clients to generate narrative meaning about what might be possible in the future and may enable clients to take actions based on hope and new possibilities (Clark, 1993; Mattingly, 1994; Polkinghorne, 1996).

In summary, establishing a collaborative relationship requires that clients be willing to actively engage as partners in the therapy process and that therapists be willing to offer and finely adjust therapy activities on the basis of clients' priorities and a careful reading of their desires, motives, and experiences of therapy.

Phase Four: Sustaining the Therapeutic Partnership

Once a collaborative partnership has been established and the client and therapist are mutually engaged in the therapeutic process, the communication between therapist and client must continue in regard to the client's experiences, the need for revision of goals and plans, and the fluctuations in need for affiliation and relationship or autonomy and privacy (Tickle-Degnen, 2002). As the relationship grows more comfortable, the client and therapist may take more risks in communication, or they may become less attentive. In all phases of the therapeutic relationship, communication errors or misunderstandings can occur that threaten the relationship and require attention, sensitivity, responsiveness, and correction (Tickle-Degnen, 2002). Therapist and client continue to explore additional intervention options and make decisions about outcome goals, needed community resources and supports, and termination of therapy when therapist and client are satisfied with outcomes that have been achieved (Tickle-Degnen, 2002).

Several scholars have theorized that the therapeutic relationship and roles within the relationship change as the client acquires competence, confidence, and independence in problem solving and in managing and directing his or her own life (Peloquin, 1990; Price, 2003). For example, therapists are often quite directive at the beginning of therapy in teaching strategies, physically assisting or *doing with* clients to encourage them and ensure success. However, research has shown that as clients demonstrate emerging abilities, therapists' roles change to that of corrector; and as clients achieve competence in skills, therapists' roles change to that of follower or coach (Clark, 1993; Gahnström-Strandqvist et al., 2000; Guidetti & Tham, 2002; Price, 2003).

Phase Five: Enduring Relationships

Paddy and colleagues (2002) suggested that there is a fifth phase to the therapeutic relationship, in which the relationship endures after the formal process of therapy is terminated. The following client's description of her ongoing

relationship with her therapist illustrates what Paddy and colleagues called "being held in mind":

> I feel like she has me in her mind when she's doing things. I may not have talked to her for quite a few months . . . when there's been a long gap, I can just ring her up when I need to. . . . It seems that when she comes across something that is suitable she thinks of me and that's really brilliant. . . . I feel that I'm always with her. (p. 17)

This client's reflections demonstrate that the quality of the therapeutic relationship has an enduring impact on both therapist and client.

THERAPEUTIC PROCESS IS INTERTWINED WITH AND PROPELLED BY THE THERAPEUTIC RELATIONSHIP

The therapeutic relationship and the intervention process are dynamic, intertwined, and interdependent as they influence each other (Gahnström-Strandqvist et al., 2000; Guidetti & Tham, 2002; Price, 2003; Rosa & Hasselkus, 1996). As therapist and client deepen their understanding of what is important to the client and the resources and adaptive skills the client has to draw on, the therapist adjusts and individualizes intervention. As the client begins to experience progress, the trust the client feels for the therapist deepens. If the client and therapist feel that the client is ready, they may increase the complexity, demands, or risk of the therapy, with the therapist close by if the client needs assistance.

> **The therapeutic relationship and the intervention process are dynamic, intertwined, and interdependent as they influence each other.**

The therapeutic process includes all of the multiple actions, interactions, activities, and strategies that occur among therapist, client, and family that help the client and family move toward the desired outcomes. In studies of the practices of experienced therapists, therapists work from the tacit knowledge they have developed through practical experience, continuously improvising, creating, negotiating, and directing the therapeutic conditions toward the mutually desired goal (Crepeau, 1991; Mattingly & Fleming, 1994; Price, 2003). Using a blend of professional and empathetic competence (Guidetti & Tham, 2002; Peloquin, 1990) and scientific and narrative understandings (Mattingly, 1994), the therapist employs numerous strategies (Price, 2003) to keep the therapy process moving toward the outcome and to develop and maintain the therapeutic relationship (see Table 33.1).

Five stages of the therapy process parallel and intersect with the process of relationship development described above. The stages of the therapy process are (1) being there and understanding the client, (2) engaging the client, (3) working together, (4) enabling occupational performance, and (5) achieving outcomes. These stages do not occur in a discrete, linear manner; rather, the roles the therapist and client assume and the strategies the therapist uses shift and blend throughout the therapy process.

The outcome toward which a therapist and client work will have a significant influence on what they decide to do in therapy and how. Achieving outcomes that are valued and satisfying to both the client and the therapist is the overarching theme and the hallmark of a strong interpersonal connection between the therapist and the client (Gahnström-Strandqvist et al., 2000; Rosa & Hasselkus, 1996). In a study of therapeutic strategies used by occupational therapists to conduct self-care training in rehabilitation settings, Guidetti and Tham (2002) concluded that the therapists used various strategies to enable clients to achieve independence and adaptation in managing themselves in a "new body in a new everyday world" (p. 273). Through the process of self-care training, therapists helped clients to confront their disabilities, acknowledge their abilities, and develop their capacities for problem solving and adaptation, which ultimately helped them to regain a sense of control, autonomy, and independence in their lives. As clients move from a more or less dependent and therapist-directed position to a more independent and self-directed position, the therapeutic relationship changes and mirrors the therapeutic process as it evolves. The strategies that a therapist uses also change as the client becomes more competent and self-directed.

Stage One: Being There and Understanding the Client

The first stage of the therapeutic process, *being there,* includes all of the actions a therapist takes to express the desire to deeply understand the client and his or her experiences, desires, motivations, fears, and hopes (Peloquin, 1990; Rosa & Hasselkus, 1996). These actions parallel the process of *developing rapport.* In developing rapport, the therapist conveys that he or she honors the client's dignity, respects the client's personhood, and empathizes with the client's situation.

Therapists build rapport through their actions. To convey respect, therapists begin by introducing themselves and explaining the role and objectives of occupational therapy. To maximize the client's privacy, therapists might close a door or curtain before providing information about the evaluation and therapy process. Therapists convey interest by maintaining appropriate and respectful eye contact, leaning slightly toward the client, and maintaining an open posture. It is important to discern the depth of sharing the client is ready to engage in and to engage at that level of intimacy. To encourage and assist the client to express emotions and thoughts, therapists use a similar tone to reflect back their

understanding of what the client may be feeling (Tickle-Degnen, 2003). The therapist can then ask the client to elaborate on or confirm what was conveyed. Showing care can help the client to feel more at ease and be more willing to engage in the therapy process.

To understand a person's occupational profile, therapists ask about the client's life, fears, concerns, priorities and previous occupations, including hobbies and interests, and try to understand the meaning these hold for the client (McAndrew, McDermott, Vitzakovitch, & Holm, 1999). Therapists might start by using a formal interview tool, such as the Canadian Occupational Performance Measure (Law et al., 1990) to begin a dialogue with the client about occupational priorities. Following a formal interview, therapists might ask more informal questions such as "What do you enjoy about [occupation]?" that will provide clients with an opportunity to express what they care about. To help with envisioning potential outcomes, therapists then ask about the client's resources and supports in the community (McAndrew et al., 1999).

Clients' desire for collaboration may vary (Cipriani et al., 1999). Some clients want to be involved in making all decisions about their care, while other clients want the "expert" to tell them what to do. A client might have cognitive limitations that make it difficult to process information and make decisions. In this case, consulting with a person close to the client helps to understand the client's needs and desires. Ultimately, the goal is to support the client to be involved in making plans and goals; however, this might not be possible with all clients (Cipriani et al., 1999).

On the basis of an understanding of the client's life, resources, priorities, and concerns, therapists assess the client's ability to perform meaningful tasks and occupations in the most natural context possible within the parameters of the setting (Price, 2005). Therapists share the results and implications of the evaluation and provide intervention options that are informed by evidence and address the client's goals, priorities, and adaptive style (Spencer, 1993; Tickle-Degnen, 2002).

Stage Two: Engaging the Client in the Therapy Process

The second stage of the therapy process is *engaging the client in the therapy process.* Because the outcomes of occupational therapy often require transformation and adaptation, clients must take an active role in their own recovery. A client might be open and willing to engage in a therapy process if he or she feels that therapy will help. Another client might have difficulty engaging in occupational therapy. Clients might resist occupational therapy, be suspicious of therapy, or fail to see the relevance or opportunity for help. Therapists use several strategies and subtle negotiations to help the client generate meaning and motive for participating in therapy (Gahnström-Strandqvist et al., 2000; Mattingly, 1994, 1998; Price, 2003). Some options

include "planting a seed" (Gahnström-Strandqvist et al., 2000, p. 20) by spending time with the client, providing information and options, and ensuring that the client has control in decision making, including the decision to participate in therapy.

In hospital settings in which clients must receive a certain amount of therapy each day to remain on the unit, the need to *engage the client in the therapy process* is more urgent. The therapist must be careful not to manipulate or coerce the client by threatening, as this approach will certainly preclude the development of rapport and collaboration. Giving information, options, and control over the decision to participate in therapy within a certain time frame puts the client and family at the center of decision making and will potentially strengthen the relationship.

Therapists use their professional knowledge to explain the disability or disease process, help clients to envision possible outcomes, and identify goals and therapy activities that are substantiated by research evidence (Mattingly, 1994, 1998; Spencer, 1993; Tickle-Degnen, 2003). Explaining the purpose of the therapy activities in relation to the client's life or asking a client to engage in challenging tasks to help the client self-appraise strengths and limitations can generate meaning and desire for participating in therapy. Therapists might use a scale such as the Functional Independence Measure (Center for Functional Assessment Research, 1996), a videotape, or another client to help the client understand the therapy process and to generate intentionality to engage in the hard work of therapy.

Engaging the client in the therapy process parallels and intersects with the second phase of the relationship: *establishing trust.* By providing the client with an opportunity to engage in meaningful activities, the client can better experience and appreciate his or her abilities and limits and begin to trust the therapist and the therapy process, even if tentatively (Figure 33.2).

FIGURE 33.2   Child and therapist develop a trusting relationship.

Stage Three: Working Together

Working together corresponds with the third phase of relationship development: *developing a collaborative relationship.* The most satisfying therapy experiences are those in which the client and therapist are equally invested and engaged in the therapy process, each bringing his or her own expertise. Therapists bring their professional knowledge and experience, and clients bring expertise about their lives, roles, occupations, and adaptive styles. Therapists provide information about the evaluation process and results and offer best treatment options based on both evidence and an understanding of the client's priorities. Together, the client and therapist establish goals and outcomes of therapy and embark on a sometimes difficult road to develop the knowledge and competence the client will need to live a satisfying life (Gahnström-Strandqvist et al., 2000).

The following excerpt from an observation of an occupational therapist as he conducts an initial evaluation in the home of a woman who had sustained multiple injuries in a bicycle accident illustrates the goal-setting process (Price, unpublished data).

> The therapist asks her about her hours, responsibilities, organizational strategies, and other activities outside of work. After he does several physical and cognitive assessments with her, he asks, ". . . What things do you want to accomplish? What are some of the expectations you have for yourself as far as personal goals . . . ?" She replied . . . "I want to be able to get back to work . . ." At the end of the session, he summed up his understanding of her priority for therapy, "We're gonna [help you] to return to work . . ."

Stage Four: Enabling Occupational Performance

The initial stages of intervention are marked by trial and error in identifying intervention activities, mutual problem solving regarding approaches, and revisions in plans and outcomes. Therapists use various strategies to engage in a collaborative relationship based on mutual effort and joint problem solving that will enhance the client's occupational performance.

Provide Options and Choices of Therapy Activities

Therapists ask clients whether they want to do certain therapy activities; the client may decline or offer alternatives. For example, a client-informant in a study by Cipriani and colleagues (1999) mused, "she'll ask if I want to do it . . . if I don't feel like it I'll tell her so" (p. 51). Another patient, Mary, said her therapist gave her the opportunity to make decisions about therapy activities, "If I want to do certain things, she lets me do them" (Cipriani et al., p. 51).

Therapists use a variety of strategies to help the client fully engage in and improve occupational performance through the therapy process (Gahnström-Strandqvist et al., 2000; Guidetti & Tham, 2002). These strategies emphasize the client doing occupations to get a feel for limitations and abilities. Therapists grade the difficulty of the activities, change the physical and social demands in the environment, and provide more or less support, depending on the client's needs. Often, therapists help clients to generate adaptations or teach clients to problem-solve and generate their own solutions.

Developing the Client's Capacity for Generating His or Her Own Solutions

To help a client problem-solve, therapists need to convey trust in the client's abilities to perceive, through experiencing himself or herself doing occupational activities, the skills the client needs to develop personal solutions. Therapists often wait, let the client attempt to work out the problem, and intervene when the client needs support. Sometimes, therapists encourage the client to engage in an occupational activity that the therapist believes the client is capable of performing, even when the client is unsure of the outcome. This approach conveys the therapist's confidence in the client but also elicits the client's trust in the therapist's professional judgment and expertise in assessing the client's ability and potential. Mutual respect, confidence, and joint effort reinforce the collaborative relationship.

Adjusting the Task and Environmental Conditions

Therapists fine-tune the demands and opportunities of the therapy conditions to provide the right amount of challenge for clients. This approach is easiest to implement when intervention occurs in natural settings such as home, school, community, and work (Dunn, Brown, & McGuigan, 1994; Hocking, 2001; Pierce, 2001, 2003). However, when this is precluded by the intervention setting, such as in acute rehabilitation settings, asking about the client's previous and current habits, patterns, and routines and conducting a visit to home, community, school, or work help therapist and client to visualize the client's physical and social environments and create therapy conditions that are closer to real life for the client. While observing the client perform desired activities, therapists adjust the difficulty of the tasks by breaking tasks down into smaller steps, adding adaptive equipment, teaching an adaptive technique, or instructing in energy conservation techniques. Encouraging the client to try different solutions based on the therapist's experiences of what has worked for others can enable the client to develop strategies that optimize occupational performance (Unsworth, 2005). Teaching the client to problem-solve her or his own solutions can enhance problem solving, autonomy, and control in unfamiliar and challenging situations in the client's future

life (Mattingly & Fleming, 1994; Mitchell, Ward, & Price, 2006). Therapists provide opportunities for the client to generalize his or her problem-solving skills and strengthen a sense of personhood by having the client practice in a variety of social settings that are not adapted. Community outings often provide potent experiences for both clients and therapists to give clients confidence to forge ahead in their social worlds (Jackson, 1998).

Using Time Strategically

Occupational therapists take the time to let clients work at their own pace (Gahnström-Strandqvist et al., 2000; Guidetti & Tham, 2002). Therapists use professional judgment to discern when to let the client continue and when to step in. Stepping in too early or rushing through an activity just to get tasks done stifles the adaptation process and diminishes the client's opportunity to engage in problem-solving his or her own situations.

Another way in which therapists and clients use time strategically is by using time as markers for progress (Guidetti & Tham, 2002). Efficiency in completing one's morning self-care routine, crossing at a street light, or completing grocery shopping can be an important goal for a client and may make a difference in whether the client can live and function independently or with assistance.

Adjust the Therapist's Role According to the Client's Need

Therapists use themselves as therapeutic agents when they shift their roles in relation to the client's needs and abilities. Therapists shift among multiple roles such as director, coach, supporter, and follower, fluidly responding and using multiple strategies (Gahnström-Strandqvist et al., 2000; Guidetti & Tham, 2002, p. 257; Price, 2003, 2006). Therapists are often in the leader role at the beginning of a therapy process, focusing the client's attention, teaching and demonstrating techniques, generating ideas, and offering solutions. As the client engages in and begins to experience success in problem-solving occupational performance problems, therapists assume a more corrective, supporting, or coaching role (Hasselkus, 2002; Price, 2003). As the client acquires competence in problem solving and occupational performance, therapists become followers, even distancing themselves from the clients by staying quiet, moving away, or leaving the room (Guidetti & Tham, p. 268). These strategies convey confidence in the client and help to engender a sense of competence, one desired outcome of occupational therapy.

As clients develop their own problem-solving skills and competence in occupational performance, therapists' roles and strategies change in response. The therapeutic relationship is embedded and intertwined in this forward-moving process. As the client experiences success, more trust is built between therapist and client. The client trusts the therapist's professional expertise, and the ther-apist trusts the client's emerging capacities for autonomy. This enables the therapist and client to decide when to increase the complexity and difficulty of the therapy demands and when the client is ready to take more risks. Often, as therapy progresses, the client's needs will shift between interdependence with the therapist and the need for autonomy (Tickle-Degnen, 2002). Sustaining the therapeutic relationship through this dynamic process takes vigilance and a keen perception of what the client is experiencing, good communication, and a responsiveness to finely adjust the therapy demands and opportunities.

Stage Five: Outcomes

Finally and ideally, the outcomes of therapy have set the client on a trajectory that will enable him or her to reach desired goals; live a fulfilling life engaging in desired occupations; have control, autonomy, and confidence in managing life; and be optimistic about the future (Gahnström-Strandqvist et al., 2000; Guidetti & Tham, 2002; Rosa & Hasselkus, 1996). The therapeutic relationship between therapist and client, whether positive or negative, often endures long after formal therapy ends (Paddy et al., 2002). Therapists hold a narrative vision of successful clients as having "an expanded and enriched life world" (Gahnström-Strandqvist et al., 2000, p. 17). Clients who have had a good therapeutic relationship with their therapists feel that they are "held in mind" (Paddy et al., 2002, p. 17), that is, clients could call the therapist at any time and the relationship and partnership would still be intact. While reflecting on the experience of occupational therapy, one client said, ". . . it will be the occupational therapist that will spend, you know, the rest of your life . . . they would always be there for you" (Mitchell, Ward, & Price, 2006). Clients often come back months after therapy ends to thank therapists and to share stories of the significance of the therapy and the therapist in helping them resume their lives.

The therapeutic relationship is central to the occupational therapy process (Devereaux, 1984; Peloquin, 1990; Schwartzberg, 1993; Yerxa, 1967). The therapeutic process proceeds in stages and is intertwined with and propelled by the therapeutic relationship. Evidence shows that therapists use multiple personal strategies (therapeutic use of self) to make therapy meaningful and relevant. Once clients are engaged in therapy, therapists use multiple personal strategies to adjust and individualize intervention. Through providing the right amount of challenge and support, clients experience success, which increases the trust and confidence clients and therapists have in each other. The strengthened relationship sustains and boosts the therapeutic process toward mutually satisfying outcomes and endures long after therapy ends.

AN EXAMPLE FROM PRACTICE

Data from observations and interviews (Price, 2003) illustrate the numerous strategies and negotiations that one therapist used to develop a therapeutic relationship. The example shows that the therapeutic relationship is embedded in and drives the therapeutic process.

The data is from one observation conducted with a therapist, Nancy, as she worked with Hannah toward Hannah's goal of going to school and being a friend. The data demonstrate that Nancy used numerous personal strategies with Hannah, such as storytelling and pushing Hannah to stay engaged, to keep her moving toward their mutually desired goal (Clark, 1993; Mattingly, 1994; Price, 2006). Their relationship—specifically, the trust and confidence they had in each other—kept them mutually engaged and moved the therapeutic process forward.

Nancy and Hannah began working together when Hannah was two and a half. Hannah's mother explained that from the time Hannah was a very young child, she was afraid of anyone other than her mother. Hannah screamed and cried when Nancy first began to see her for therapy. Hannah, now four, was still very stilted and quiet around other children; however, during sessions without other children, she was spontaneous, playful, and talkative with Nancy. Throughout therapy, Hannah and Nancy maintained a therapeutic relationship that enabled occupational performance. Nancy sustained the relationship by finding a balance between supporting and pushing Hannah to increase her performance and competence in a more expansive play repertoire and in becoming a member of a social group. Table 33.2 provides an abbreviated overview of the observation and interpretations of the phases and stages of the therapeutic relationship and process to illustrate the strategies Nancy used to move the process forward. The example illustrates the blending of professional and empathic competence in the process of therapy between Nancy and Hannah (Gahnström-Strandqvist et al., 2000; Peloquin, 1990). Hannah trusted Nancy to provide her with the right amount of challenge. Nancy's confidence in Hannah's emerging abilities enabled Hannah to embark on a transformation that she and her mother could not have made happen on their own (Lawlor, 2003). Hannah's mother, Susan, talked about the progress she observed in Hannah's comfort and ability to engage with family, neighbors, and friends because of seeing Nancy. Then she talked about their relationship:

> Hannah adores Nancy. I think, for Hannah, Nancy was the first person who she felt loved her and challenged her at the same time. I think Hannah, she has such a respect, she has such a different relationship with Nancy . . . it's almost like she wants to like show Nancy what she's accomplished. But at the same time, I think she feels like equal with Nancy; like there's like a trust level there, of that she knows that if she tries something and it doesn't work, it's okay too.

Susan's description of Nancy and Hannah's relationship illustrates that the therapeutic relationship, based on mutual respect and confidence, is embedded in the therapeutic process and that the therapeutic process is a blend of empathic and professional competence (Gahnström-Strandqvist et al., 2000; Peloquin, 1990).

CONCLUSION

Occupational therapists often enter clients' lives as they face significant life challenges that preclude them from participating in "life as usual." Therapists are compelled to quickly create therapeutic relationships that convey respect, empathy, and a willingness to "be there" and "do with"; these actions and attitudes engender trust and establish rapport. Because achieving outcomes that are both achievable and desirable can be a complex and difficult process, clients need therapists who are both professionally and empathically competent (Gahnström-Strandqvist et al., 2000; Peloquin, 1990, 2003). The degree to which therapists are willing and able to enter the life worlds of clients and listen deeply to and experience their hopes and fears will determine the degree of collaboration clients and therapists can undertake to develop meaningful interventions (Van Amburg, 1997).

Therapeutic relationships develop in phases: *developing rapport, establishing trust, developing a collaborative partnership, sustaining the therapeutic relationship,* and *holding enduring relationships* after formal therapy has ended. Therapists use multiple personal strategies, such as asking clients to tell stories about their lives, concerns, and priorities. Therapists carefully and intently listen and reflect back empathy and understanding. Therapists *do with* clients until they can do on their own; even then, therapists "hold in mind" their patients and relationships (Paddy et al., 2002).

The therapeutic process is intertwined with and propelled by the therapeutic relationship. The therapeutic process also evolves in stages: *being there and understanding the client, engaging the client in therapy, working together, enabling occupational performance,* and *achieving outcomes.* Therapists use multiple strategies to help clients experience their abilities, limitations, and adaptive capacities through engagement in therapy activities. Therapists adjust the therapy demands to provide the right amount of physical, social, and emotional challenge while also adjusting their roles and levels of support. Through a complex synthesis of professional and empathic competence, therapists enable clients to take up or resume lives of possibility (Gahnström-Strandqvist et al., 2000; Peloquin, 1990).

TABLE 33.2   ANALYSIS OF HANNAH AND NANCY'S THERAPY PROCESS AND RELATIONSHIP

Observation and Interview Data	Phases and Stages of Therapeutic Relationship Development and Process and Strategies Used
Hannah: My legs got bigger. **Nancy** (*gestured growing up with her hand as it moved higher*): Oh, my gosh, you are bigger! Do you think maybe you'll be ready for school pretty soon? **Hannah:** Um hm (*yes*), my school's not open yet. **Nancy:** You know, a lot of other kids are waiting too, to go to school. **Hannah:** Hm. **Nancy:** And those might be good friends, huh? **Hannah:** Hm, cause I'm growing real real up. **Nancy:** You are. You know, you're gonna be ready for school. You're gonna be fine. **Hannah:** Hm.	**Phase 3 of relationship development:** sustaining their relationship **Stage 4 of therapeutic process:** enabling occupational performance **Strategies:** ◆ Conveying trust and confidence in Hannah's abilities and potential to reach her goal ◆ Occupational storytelling and storymaking (Clark, 1993; Mattingly, 1994, 1998): Hannah's long legs mean that she is getting ready for school and to become a friend
Nancy: You know, Hannah, I'm kind of hungry for spaghetti. **Hannah:** (*No response*) **Nancy:** You know what, we're just pretending. This is my little plate (*the lid to the play dough container*). I'm so hungry. **Hannah:** Hm, I'm making it. (*She began cutting the thin strips into pieces.*) **Nancy:** Are you the cook? **Hannah:** Um hm (*yes*). (*Hannah put two chunks of play dough on Nancy's "plate."*) **Nancy:** Oooh! Are those the meatballs? **Hannah:** Um hm (*no*). **Nancy:** What are those? **Hannah:** Play dough. **Nancy:** Well, we have to pretend. What is it? I can't eat play dough. **Hannah:** Hm hm (*no*). **Nancy:** What is it? **Hannah:** That's a pretend. **Nancy:** What should I pretend this is? **Hannah:** Hm. Chewy. **Nancy:** It's chewy. Uh, is it a piece of bread? **Hannah:** Hm hm (*yes*). (*Hannah put clumps of play dough on the "plate."*) **Hannah:** Here's the food. **Nancy:** Is it ready to eat? **Hannah:** Hm.	**Stage 3 of therapeutic process:** creating a social situation in which they would work together to explore Hannah's limitations and activate her resources **Strategies:** ◆ Adjusting therapy strategies to use Hannah's resources, strong cognitive skills, to teach Hannah what other children would learn tacitly
Nancy: Yes? **Hannah:** Now it's white. **Nancy:** Wait. I want to eat first. . . . better see if I like it. Want a bite? **Hannah:** Um hm (*no*). **Nancy:** Here. Have a pretend (*held the dough up to Hannah's mouth*). Look at my lips. You don't have to really eat it. (*Nancy put the dough up to her mouth and smacked her lips.*) You just pretend and it makes a sound.	Hannah tries to escape from the pretend play by declaring that it is time to play with the white play dough. **Strategies:** ◆ Pushing Hannah to stay with the demands ◆ Conveying trust that she could do it ◆ Drawing on Hannah's trust that Nancy would not demand more than she could handle ◆ Providing opportunities for Hannah to explore her limits, create strategies, and draw upon her resources

**TABLE 33.2   ANALYSIS OF HANNAH AND NANCY'S
THERAPY PROCESS AND RELATIONSHIP**   *Continued*

Observation and Interview Data	Phases and Stages of Therapeutic Relationship Development and Process and Strategies Used
Hannah *(watched):* hm. **Nancy:** Okay, you try. Look, Hannah. *(Nancy held the dough up to her mouth, smacking, then held the dough up to Hannah's mouth, who reluctantly smacked.)* Here, have another bite. **Hannah:** Okay. *(Nancy smacked, and then Hannah smacked.)* **Nancy:** It's delicious. Give me five; you're a great chef! **Nancy:** Why don't you like to pretend to eat those things? Why do you think? Is it too silly *(Hannah: hm)* or you just don't like it? **Hannah:** I don't like it. **Nancy:** You don't like it. *(whispered)* But you know what? **Hannah:** hm? **Nancy:** Sometimes, if you're at school, you might have to pretend with the kids. **Hannah:** Okay. **Nancy:** You know that? So, even if you don't like it. **Hannah:** Can I get white? *(Nancy tried to get Hannah to pretend to eat some spaghetti, and Hannah was very reluctant.)* **Nancy** *(acquiescing):* I'll get white. *(whispered to Hannah):* You know what? Sometimes, little girls like to pretend. Did you know that? **Hannah:** (unclear). **Nancy:** Let's take some deep breaths, okay? **Nancy:** *(Hannah resumed cutting dough)* Do you know what I think? Maybe you'll make some food for me. But you know, I don't have any plate. I have to make one. **Hannah:** With play dough, like pretend. **Nancy** *(softly):* Like pretend, that's right, sweetie. *(Nancy made a small bowl out of play dough as Hannah continued cutting.)* **Nancy:** Hannah? **Hannah:** hm? **Nancy:** Do you think you could give me some play dough soup? **Hannah:** All right. *(Hannah pretended to fill the bowl.)* **Nancy:** Oh, thank you! It's very good. What did you put in it? **Hannah:** Hm. Hm. Rice. **Nancy:** Nancy: Hmm. *(pretend slurp)* You want a taste? *(Nancy put the spoon up to Hannah's mouth, and Hannah pretended to taste.)* **Nancy:** Oh, that was a good taste.	**Strategies:** ◆ Praising Hannah, a narrative strategy that conveys confidence in Hannah that she is moving toward her goal **Strategies:** ◆ Engaging Hannah in problem solving and self-appraisal ◆ Conveying respect for Hannah's experience ◆ Drawing on Hannah's resources, strong cognitive skills, to teach her what other kids would learn tacitly ◆ Going with Hannah's time rhythm, knowing when to give her a break ◆ Storymaking (Clark, 1993; Mattingly, 1994) to increase the demands of therapy and to expand Hannah's play repertoire, to enable her to make and keep friends in preschool ◆ Drawing on Hannah's personal resources (Kielhofner, 2002): breathing is a strategy that Nancy taught Hannah to use and that Hannah could use to calm herself **Relationship development:** Nancy conveys confidence in Hannah by asking her to reengage; Hannah conveys trust in Nancy by reengaging **Therapy process:** Hannah demonstrated her learning by pretending; **Strategy:** ◆ Praising Hannah softly. A breakthrough; Hannah demonstrates that she can pretend, even if she does not like it; a highly narrative moment (Mattingly, 1998) that symbolizes Hannah's ability to engage in play that would help her to make and keep friends

Source: Adapted from Price (2003).

PROVOCATIVE QUESTIONS

1. Reflect on Nancy and Hannah's interactions: How do you think the therapy process and outcomes would be influenced if emphasis on the therapeutic relationship was minimized?
2. How would you feel and what would you do if your therapy process with a client was not effective?

The Interview Process in Occupational Therapy

ALEXIS D. HENRY AND
JESSICA M. KRAMER

> "I interview because I am interested in other people's stories. . . stories are a way of knowing."
>
> —IRVING SEIDMAN (1991)

Learning Objectives

After reading this chapter, you will be able to:

1. Describe the use of interviewing as an evaluation procedure in occupational therapy.
2. Identify features of an effective interview.
3. Identify available standardized interviews and self reports designed to identify clients' occupational needs and desires.

After reviewing preliminary information about a client, interviewing is the first step in conducting a client-centered evaluation and developing an occupational profile (American Occupational Therapy Association, 2002). Interviewing is an essential skill for one of the most common assessment procedures used by occupational therapy practitioners. The goals of interviewing are both product and process. Beyond gathering information (product), interviews are useful because they help to develop a therapeutic alliance with the client (process).

WHAT IS INTERVIEWING?

Interviewing has been defined as a shared verbal experience, jointly constructed by the interviewer and the interviewee, organized around the asking

and answering of questions (Mishler, 1986). While your "job," as the interviewer, is primarily to ask the questions and the client's "job," as the interviewee, is primarily to answer, effective interviewing does not proceed in a stilted, "stimulus-response" manner. Rather, you and the client are attempting to achieve some shared understanding of a particular reality. That reality is the client's story.

When you first meet a client, the information that you are most likely to have is a label that identifies the client as having a particular type of problem. Most often, this label takes the form of a diagnosis; for example, the client might have a diagnosis of schizophrenia or arthritis or a learning disability. The diagnosis is likely to lead you to make certain assumptions about the occupational performance problems this client might have, based on either your past experience with other people who had that same diagnosis or your textbook knowledge of the diagnostic condition. But in reality, information such as a client's diagnosis has limited usefulness in influencing the course of intervention. To develop a meaningful intervention plan, you need to know the particulars of the client's situation, and you need to know them from the client's perspective. In other words, you need to understand the client's story.

When a practitioner considers how the client's present situation fits into the client's larger life story, the practitioner is thinking narratively about the client (Clark, 1993; Franits, 2005; Frank, 1996; Helfrich & Kielhofner, 1994; Mattingly, 1991). A narrative or life story approach involves considering the particular set of circumstances that describe a client's life before he or she came for intervention, how the client views his or her life now, and where the client sees that life going after intervention. When thinking narratively, the practitioner strives to understand the client's values and motives in order to make interventions meaningful.

Interviews are strategies that can help you to think about the client in narrative terms. The client's story, goals, concerns, and aspirations are essential for determining the course of intervention. When there is a mismatch between your perception and the client's perception of what is needed, interventions are likely to become stalled (Mattingly, 1991). A shared perception of what is needed can best be achieved through a dialogue between you and the client.

Interviews are structured strategies for engaging the client in a dialogue, although interviews function best when they proceed as normal conversation rather than as a formal question-and-answer session. An interview should always take place at the beginning of the intervention process. At the beginning of intervention, one important goal of an interview is to gather specific information about the client. In this way, an interview is one of many procedures that might be used in a comprehensive evaluation of a client. However, because it is an interaction between you and the client, an interview is also an intervention that can have therapeutic value in its own right. In the context of an interview, you and the client can together begin to construct a new life story for the client (Mattingly & Fleming, 1994).

WHEN AND WHOM TO INTERVIEW

The Initial Interview: Interview as Assessment

Because interviewing is an integral part of a comprehensive evaluation of a client's occupational functioning, it most frequently occurs at the beginning of your work with a client. During this initial interaction, your goal is to begin to understand the client's story (see Box 34.1). The second, but not unrelated, goal is to begin to form a collaborative relationship with the client. These and other goals of interviewing will be discussed later in this section.

> **BOX 34.1** **PRACTICE NOTES**
>
> In my own practice, when I worked on an inpatient psychiatry unit, an interview was almost always my first significant interaction with a new patient. Before administering any other assessment, I would sit down with the patient to talk. Who is this person? What brought the person here? What does the person care about? Where does the person hope to go from here? The answers to these questions were important in shaping the recommendations that I would make for the work we could do together in the time we had. *AH*

During the Course of Therapy: Interview as Intervention

Although interviewing is virtually always done at the beginning of an intervention process, the beginning is not the only time an interview may be appropriate. An interview that occurs after your work with a client has begun can be both a form of reevaluation and an intervention. Such interviews are usually less structured than the data-gathering process used during the formal initial evaluation phase. This more informal kind of interaction can involve you and the client in reviewing what has happened thus far and anticipating and planning for the future. This discussion can help the client to construct an image of a future self who is able to do more than the client can do now. Such images are important in making the intervention something the client can commit to and invest in (Helfrich & Kielhofner, 1994; Polkinghorne, 1996). In addition, reviewing your work together can be a useful strategy when you seem to be at a "stuck" point, when it seems that the intervention is not progressing. Together, you and the client can ask, "Why is this not working?" and "What can we do to make things better?" In these ways, interviewing is a collaborative tool that is used repeatedly throughout the intervention process.

Interviewing Older Adolescents and Adults

Most older adolescents and adults that you will encounter in practice are appropriate candidates for interviewing. The techniques for interviewing that are discussed later in this section apply, for the most part, to interviewing individuals of these ages. However, some people are not appropriate candidates for interviews or should be interviewed only in highly structured situations. For example, individuals with severe depression might have difficulty concentrating on and responding to interview questions; people with mania might be too distracted by external stimuli to attend to an interview. People with psychosis might have such disorganized thinking that their answers to questions are difficult to understand. People with expressive or receptive language deficits (e.g., aphasia) might either not comprehend questions or not be able to respond even if they understand. If an interview is approached as a conversation, a time when you and the client are going to "talk," rather than as a formal evaluation of the client, then either continuing or discontinuing the interview (if that seems necessary) can be done without making the client feel that he or she has failed the evaluation.

Interviewing Children and Younger Adolescents

Although pediatrics is one of the largest practice areas in occupational therapy, until recently, few interview procedures had been developed to gather data on children's occupational behavior directly from children. Some advances have been made in developing interview and other self-report procedures for use with children; some of these procedures will be discussed later in the chapter.

Children pose a unique challenge for the interviewer. The ability of children to describe their experiences and their feelings depends on their acquisition of the requisite cognitive, linguistic, and social skills (Krahenbuhl & Blades, 2006; Stone & Lemanek, 1990). Before the age of 7 or 8 years, most children describe themselves only in terms of observable characteristics and behaviors and make differentiations between themselves and others on the basis of these observable traits rather than on internal states. For example, a young child may be able to describe herself in terms of the physical attributes (e.g., "I have blue eyes."), possessions (e.g., "I have a cat."), or preferred activities (e.g. "I like to ride my bike."). However, these notions about the self are not integrated into a global self-concept (Stone & Lemanek, 1990). In addition, young children may have difficulty labeling or verbally communicating their subjective emotional state (LaGreca, 1990). Young children also have difficulty relating events in a temporal order, especially if the events happened in the (relatively) distant past.

At around age 8 years, children acquire a more global sense of the self. After this age, children are better able to report on their thoughts and feelings and to provide more accurate information on diverse experiences and situations. During adolescence, the capacity for self-reflection increases further. Adolescents have the capacity to describe themselves in abstract psychological and interpersonal terms rather than the concrete, physical terms used by younger children. In addition, adolescents begin to evaluate their own thoughts and behaviors critically and to analyze others' reactions to their behavior (Stone & Lemanek, 1990). Thus, as self-awareness increases, older children and younger adolescents are able to respond to interview questions with increasing sophistication. However, the increased use of social comparisons and greater psychological awareness that come as children age may contribute to a tendency to respond to interview questions in a socially desirable manner (Stone & Lemanek, 1990).

Other factors can influence the way in which children and adolescents respond during interview situations. One of the most important to consider is the inherent power imbalance in the relationship between a child and an adult interviewer (Cohn, 1994). Adults generally have greater social power than children do; children are, for the most part, socialized to respond to adults in ways they think adults want to hear. Because of the power imbalance, whether real or merely perceived, children may unintentionally fabricate answers to questions to please an adult interviewer (Cohn, 1994; Krahenbuhl & Blades, 2006).

Establishing rapport and a sense of trust is critical to the successful interview. With children, engaging the child in a play activity or a discussion about a favorite book or movie before the interview can help to establish rapport (see Box 34.2). With adolescents, honest communication about the reasons for the interview and the confidential nature of the interview can help to instill

<table>

BOX 34.2

PRACTICE NOTES

Instead of immediately focusing on what a child or adolescent is having a hard time doing, start by asked the child what he or she likes and what he or she is good at doing. This lets the child know that you are equally interested in the child's abilities as well as his or her challenges and creates a safe and positive therapeutic interaction. When talking about the challenges, instead of asking children to report what they have a hard time doing, ask children what makes it difficult for them to perform to the best of their ability. This allows the child to focus on the environment in addition to his or her abilities. *JK*

</td></tr>
</table>

trust. Age-appropriate communication is another key to a successful interview. With young children, the use of simple vocabulary, short sentences, and concrete, direct questions (e.g., "What do you do during school?") can be effective. Adolescents can usually answer more complex, open-ended questions (e.g., "Tell me about how school has been going for you.").

Finally, the process of gathering information concerning children's occupations should involve other people in the child's environment, including parents and teachers (LaGreca, 1990). Because children are under the social control of others, their behavior in one environment might not be the same as their behavior in another environment. Therefore, it is important to gather information from the multiple contexts within which the child functions (see Box 34.3). Moreover, because children are referred for intervention by others, usually a parent, it is important to understand and respect the perspective of the people who may be distressed by the child's behavior (LaGreca, 1990).

BOX 34.3

PRACTICE NOTES

When I was a school-based occupational therapist, interviewing parents and teachers was an essential part of my job. However, fitting an interview into a busy IEP meeting was difficult. By breaking questions down into smaller chunks that could be answered during a quick phone call, through e-mail, or in a short discussion in the hallway, classroom, or front office, I could gather enough information to complete an assessment. *JK*

WHY INTERVIEW

Understanding the Client's Story

The single most important reason to interview the client is so that you can better understand how the client sees things. As was previously discussed, an interview is an opportunity for the client to tell you his or her story. Mattingly (1991) has noted, "a disability is something that interrupts and irreversibly changes a person's life story"; "therapy can be seen as a short story within the patient's longer life story" (p. 1000). During the course of the interview, you are trying to uncover the "plot" of the client's story. Before the interview, you might have some general information about the client. During the interview, you want to fill in the particulars of the story. So your main questions should be as follows:

◆ What happened to you?
◆ How did you get to occupational therapy?
◆ What was a typical day like for you before you came here (hospital, clinic, etc.)?
◆ What was and is important to you?
◆ Where do you hope to go after you leave here?

Asking and valuing the answers to these questions are what it means to be "client-centered" (Law, 1998). Client-centered occupational therapy is "an approach to service which embraces a philosophy of respect for, and partnership with, people receiving services" (Law, Baptiste, & Mills, 1995, p. 253). Client-centered occupational therapy interventions are individualized and developed in collaboration with the client. An interview can be an effective fist step in individualizing and prioritizing service with a particular client.

Building the Therapeutic Alliance

Because an interview is an interaction between two people, a relationship begins to develop during the course of the interview. During the interview, you want to establish a relationship with the client that will help you together to set and attain the goals of intervention. The manner in which you conduct the interview will either foster or inhibit the development of that relationship (Haidet & Paterniti, 2003). As you talk with a client, your ability to communicate a sense of concern and respect for the individual and the information being shared and your ability to be real and genuine in the interaction will go a long way toward establishing this relationship. The client has come to you for help. For the client to feel that you are someone who can be of help, a sense of safety, trust, and collaboration must develop between the two of you (Okun, 1997). An interview can enhance a sense of collaboration between you and the client, because it gives you an opportunity to communi-

cate that you care about what is important to the client. To the extent to which you have a collaborative relationship with the client, you will be much more likely to achieve intervention goals (Neistadt, 1995; Tickle-Degnen, 1995).

Gathering Information and Developing the Occupational Profile

Occupational therapy interviews are used to gather information about the client's functioning in occupations. Most interviews consider the client's current or recent functioning; some also take a historical perspective and seek to understand the client's functioning over time. Although the specific questions vary across different interviews, in general, interviews solicit information about the client's performance patterns, such as daily use of time, past and current role involvement (e.g., worker, student, homemaker, parent), play and leisure participation, and the client's values, goals, and sense of competence relative to occupations. Some interviews also ask questions about the client's current environment (human and nonhuman), to evaluate whether the environment supports or constrains the person's functioning. This information forms the occupational profile (AOTA, 2002).

It is important to gather information about the client's functioning in the past, because past functioning often is one of the best predictors of future functioning (Figure 34.1). The impairments, limitations, and restrictions associated with a particular health condition may predict a client's future to some extent (World Health Organization, 2001). But the successes a person has had in the past, particularly the recent past, are often resources on which he or she can draw. A person's goals and sense of compe-

tence are indicators of the person's desire and motivation to return to his or her prior life.

Observing Behavior

During the course of an interview, you have an opportunity to observe the client's behavior. The client's ability to participate in an interview can reveal much about his or her current functioning. You will be able to make observations about the client's energy level, stamina, affect, comprehension, memory, concentration, thought organization, physical appearance, and interpersonal behavior.

- Is the client able to actively engage with you through a 45-minute interview without fatiguing?
- Does the client appear depressed or elated?
- Does the client's memory seem intact? For example, is the client able to remember the dates of his or her last few jobs and relate them to you in chronological order?
- Does the person comprehend the questions being asked?
- Is the client able to convey his or her history in a manner that you can understand and follow?
- Is the client's thinking organized and goal-directed, or is the thinking tangential (i.e., "off track")?
- Is the client appropriately dressed and groomed for the situation, or does the client appear unkempt?
- Is the client friendly and forthcoming with information, or does the client seem angry, hostile, or resistant to being interviewed?

When you make these kinds of behavioral observations, an interview can serve as a kind of screening procedure and give you an indication of whether it might be appropriate to administer any additional assessment of performance skills. In addition, the extent to which the client engages with you during an interview may be some

FIGURE 34.1 An occupational therapist interviewing parents about their 4-year-old child.

indication of the extent to which he or she will engage in interventions. Of course, if the client appears to be defensive or resistant during the interview, it is important to ask yourself whether there is something that you are doing to make the client feel defensive.

Identifying Client Strengths and Potential Problem Areas

As the interview progresses and you begin to achieve a deeper understanding of the person's story and observe his or her behavior, you should begin to formulate an initial sense of the client's strengths or assets as well as problems that might be addressed by occupational therapy interventions. All clients, regardless of disability, bring certain strengths (current competencies, past experiences, and environmental supports and resources) to their work with you. It is important to identify these early on, as the client will be able to draw on these assets over the course of the intervention.

A set of problems will also begin to take shape from the things the client tells you and the things you observe. It is important to remember, however, that this initial idea about the problems is tentative and subject to revision as you and the client begin to work together. Moreover, your perspective of the problems the client faces might not be the same as the client's perspective. You must share your initial impression with the client to confirm the extent to which you are seeing things in the same way. This involves both restating what you have perceived as the client's major concerns and sharing your impressions and observations during the interview regarding the client's strengths and potential problems. By engaging in mutual problem setting, you lay the groundwork for a client-centered, collaborative relationship. Toward the end of an interview, you might say to the client, "Well, from what you've told me, it sound like you are concerned about . . . , and it seems to me that you are also having some difficulty with. . . ." The goal is for the two of you to arrive at an agreement about the problems the client faces.

Clarifying Your Role in the Setting

You can also use the end of an interview to elaborate on and clarify your role in the setting and the work you and the client may do together. Do not be surprised if the client does not know what occupational therapists do. At this point, you can explain what services occupational therapy offers, what options might be available to the client, whether you and another provider (e.g., a physical therapist, nurse or social worker) might be working with the client together, or whether you might refer the client to another provider for a service that occupational therapy does not offer. It is at this point that you can make initial recommendations about the possible interventions.

Establishing Priorities for Intervention

Once you and the client agree on the work to be done, you have explained your role and the services that occupational therapy can offer, and you have made some initial recommendations for intervention, then you and the client can work collaboratively to establish intervention priorities. Being client-centered means that the client's priorities should be your priorities. However, it is important to recognize other factors that might influence the recommendations you make. For example, you might be influenced by the services that are most easily provided in your setting, your own interests and competencies, and funding and reimbursement, among other things. The client's goals and priorities are central in determining the course of intervention. Engaging the client in goal setting and prioritizing is a good way to finish up an interview.

HOW TO INTERVIEW

It might seem that interviewing should come naturally; after all, you talk to people every day. But much of our day-to-day communication with other people is quite superficial. When you conduct an interview with a client, you are engaging in a dialogue with the express purpose of trying to understand that other person so that you can be helpful (Coulehan et al., 2001; Okun, 1997). Thus, "therapeutic communication" differs from day-to-day conversation in fundamental ways. Developing the communication skills that are needed to become an effective interviewer takes time and experience. The skills of effective interviewing and ways to structure a therapeutic interview are discussed below.

The Skills of Effective Interviewing

Preparing

Preparing for the interview is an important first step. Before conducting an interview, you should prepare yourself, the client, and the environment. In preparing yourself, you should have some notion of the questions you want to ask the client. Several different occupational therapy interview procedures have been published in the past several years, and these will be discussed later in this section. It is preferable to use one of the existing interviews rather than developing your own, as these procedures have generally been subjected to examinations of reliability and validity. If you are a novice interviewer, you will need to practice before interviewing your first client. Observing experienced interviewers, noting how they structure the interview, ask questions, and respond to information the client shares, is a good way to begin to develop a sense of how an interview flows. You might also practice administering the interview to a colleague or supervisor and have that person give you feedback. Videotaping and critiquing

your practice interviews can also help you to hone your interviewing skills.

Before conducting an interview with a client, you should read whatever preliminary information might be available on the client. This information can give you some initial ideas about areas on which you might focus during the interview. Moreover, information about the client's diagnosis or presenting problem can help you to anticipate how actively the client can participate in the interview, whether the client might tolerate only a short interview, or whether interviewing the client might not be appropriate at this time. In settings such as hospitals, nursing homes, or day programs, nursing staff or others who are in close contact with the client might have useful information about how the client was doing that day.

In addition to preparing yourself, you should prepare the client for the interview. When meeting a new client for the first time, make sure to introduce yourself and briefly tell the client about your role in the setting. Ask permission to do the interview, telling the client briefly about the content and purpose of the interview. Depending on the setting and time constraints, you might conduct the interview "on the spot," or you might schedule an appointment for a later time. Scheduling an appointment (even if just for later that same day) can give your client a degree of control; the client then has some choice about when he or she will see you. Some times of the day are better than others for many people. For example, many people with depression feel worse in the morning and experience improvements in their mood and energy level as the day progresses. By allowing the client to have some degree of control in a situation in which he or she might feel out of control, you help to set the tone for a collaborative relationship. Finally, you need to pay some attention to the environment in which you will conduct the interview. Obviously, a private space is the most desirable. Some of the questions you will be asking are highly personal, and a private space will make you both feel more comfortable. You should not make assumptions about what might and might not be a personal or difficult question for the client. A client might have an emotional response to a particular question that you had not anticipated. Chairs should be an appropriate distance apart (three or four feet). The room should be at a temperature that is comfortable for both of you and should be well lighted. Have tissues and water available. If it is not possible to have a private space, then creating some sense of privacy in a more open space by arranging the chairs in a corner of the room would be suitable. There might be times when you need to conduct an interview in a setting where privacy is very limited; for example, on a medical inpatient unit, you might need to interview a client in a semiprivate room who cannot leave the bed. In a situation such as this, you will want to make sure that the client feels comfortable answering your questions when others might be able to hear your conversation.

Questioning

Interviewing involves the asking of questions. The way you pose questions will influence the quality and amount of information you obtain and thus the level of understanding of the client's story you can achieve. How you ask questions will also influence how you are perceived by the client and will influence the development of your relationship with the client (Coulehan et al., 2001). In general, open-ended questions encourage the client to tell his or her story and are more likely to yield meaningful information from a client than are closed questions that require only a yes or no answer or a very brief response. For example, the question "Did you like your job?" can be answered "yes" or "no." "Tell me what you liked about your job" is a question that will likely result in a more detailed response. In addition, the use of probes and follow-up questions (e.g., "Tell me more about that") encourages the client to relate his or her story and helps to establish empathy (Coulehan et al., 2001). During the course of an interview, it is likely that you will ask two types of questions: those that are factual or descriptive in nature (e.g., "What do you do for work?"), and those that are intended to elicit more narrative data. Narrative questions yield data on events in the client's life and the client's perceptions and motives concerning events (e.g., "Tell me about a time when work was going very well for you"). Kielhofner and Mallinson (1995) suggest that effective interviewing involves a weaving of these two ways of questioning. There might be certain clients for whom a more structured, factual approach to questioning is appropriate. For example, a client whose thinking is disorganized might have difficulty answering more open-ended or narrative questions in a coherent manner but can respond to a more structured question such as "Where do you live?" It will usually be apparent when you need to use a more structured approach to the interview.

During the interview, you want to be conscious of whether the questions you are asking are making the client anxious or uncomfortable. Your intention is to put the client at ease. To do this, it is best if your questions are open, clear, singular (i.e., you ask only one question at a time), and nonjudgmental and you encourage the client to tell his or her story. You want to avoid putting the client on the defensive. Sometimes, questions that begin with "why" (e.g., "Why did you do that?") can have the unintended effect of making clients feel that they owe you an explanation about their feelings or behavior (Okun, 1997). Particularly during the initial interview, it is more useful to assume a neutral, nonjudgmental stance.

Responding

An interview needs to be more than a series of questions on your part, interspersed with answers from the client. You will need to respond to the information that the client is sharing with you. There are many ways in which you

might respond. Often, because of a desire to help, our impulse is to respond with advice or suggestions. However, particularly during an initial interview, you want to resist this impulse, at least until you have come to the end of the interview (Coulehan et al., 2001). Before that, it is doubtful that you will have sufficient information on which to base advice. So even though you want to resist giving advice until you have achieved some understanding of the client's story, you still need to respond. During the course of the interview, your responses should primarily be attempts to paraphrase what the client has just said. Paraphrasing is more than just repeating what the client has said. It involves trying to capture the essence of what the client has said and restating it in your own words to communicate your desire to understand (Coulehan et al., 2001). Paraphrasing helps you to communicate to the client that you have listened to, heard, understood, and valued the information being shared with you. Paraphrasing also allows you to confirm that you have, in fact, clearly understood the client.

There are two general types of responses that you can use during an interview: content responses and affective responses. Content responses are used when you want to clarify the facts or communicate that you have understood what the client means. A content response might begin "So, you're saying that. . . ." Content responses serve the purpose of clarifying information and meaning. Affective responses are used when you want to reflect the underlying affect or feeling tone that the client is communicating. An affective response might begin "It seems like you're feeling . . ." or "I might have felt very . . . in that situation." An affective response should be phrased somewhat tentatively until you have confirmed that the client feels this way. Affective responses serve the purpose of communicating that you are trying to understand and are concerned about how the client feels.

Attending and Observing

Attending involves the use of both nonverbal and verbal behaviors that help to communicate your interest in the client and can facilitate the development of therapeutic rapport. Nonverbal behaviors include positions and movements of the face and body, as well as qualities of the voice, such as tone, intensity, and speed (Sommers-Flanagan & Sommers-Flanagan, 2003; Tickle-Degnen, 1995). Having your chair and the client's chair either facing each other or slightly angled, about three feet apart, allows you to see the client fully and the client to see you. You can communicate your interest in the client by making frequent eye contact. Other nonverbal behaviors that communicate interest include head-nodding, smiling, and leaning forward. Verbal behaviors, such as saying, "uh-huh," "humm," "yes," or "go on," let the client know that you are listening and encourage the client to continue with his or her story. Tickle-Degnen (1995) notes that tone of voice is

an important attribute to attend to. A cheerful tone of voice is not always the most appropriate to use. Rather, a tone of voice that is genuine and conveys concern about the client may be more effective. Effective interviewers often accommodate their bodies, movements, and tone of voice to be "in sync" with the client's (Bradburn, 1992; Tickle-Degnen, 1995).

Attending also involves observing how the client seems to be feeling as the interview progresses. Does the client seem to be fatiguing? Does the interview content seem to be emotionally difficult for the client? If you sense that the client is finding the interview difficult, you should ask to verify this. For example, questions such as "How are you doing?" and "Are you getting tired?" communicate that you are concerned about the client. A common side effect of psychiatric medications is dry mouth; offering a glass of water is another way of showing that you are attending. Effective observation involves noting the client's behavior as the interview progresses.

Effective Listening

Finally, although it seems obvious to say so, throughout the interview, you need to listen to the client. Listening effectively allows you to respond effectively. Paying close attention to both the content and the underlying feeling or affect takes energy (Sommers-Flanagan & Sommers-Flanagan, 2003). Listening is more difficult than it sounds, because there are many distractions to effective listening. There can be external distractions, such as activity in the environment, or internal distractions, such as your thoughts about a meeting you just came from or your next client. Even when your attention is focused on the client, there can be distractions. Denton (1987) has identified certain blocks to effective listening to the client; she calls these *thinking about the person, thinking for the person,* and *thinking ahead of the person.*

Thinking about the person involves making judgments about the client's lifestyle, morals, and motives; such judgments can create distance between you and the client and interfere with your being able to understand the client's perspective. When you think for the person, you prematurely think about solutions to the client's problems. Because one aim of the interview is to facilitate a collaborative relationship with the client, prematurely offering solutions diminishes the client's role in the relationship and can reinforce the client's sense of helplessness. Thinking ahead of the person involves rushing the client through his or her story just to get the facts. This can happen when you feel that you already know the story, when the client is relating too much or seemingly irrelevant details, or when you feel pressed for time (Denton, 1987; Haidet & Paterniti, 2003). The reality is that you never already know the story; each person's story is unique. However, if the client is giving you more detail than you need at the moment and you begin to run out of time, you can res-

pectfully redirect the client by saying, "I can hear that this topic is very important to you. Perhaps we should set another time to really talk about this. Right now, I need to ask you some questions about something else."

Finally, particularly if you are a novice interviewer, you can be distracted from listening because you are thinking about what you should say next. If you are thinking about what you should say next, then you are not listening to the client. One way to improve your listening skills is to learn to use silence effectively. Most of us feel uncomfortable with silence and feel a need to fill a silent space as soon as it occurs. However, if you can feel comfortable taking a brief silent pause to think about what the client has just said and about what you might say next, then you will not need to prepare your next question while the client is talking. You can even say to the client, "I'm just taking a moment to think about what you've said." Rarely will you need more than 10 seconds to do this.

Structuring the Interview

Regardless of the type of interview you use, there are three phases to an interview: the opening, the body of the interview, and closure (Sommers-Flanagan & Sommers-Flanagan, 2003).

Opening

At the opening of the interview, you let the client know the purpose of the interview. Even though you probably did so when you made the appointment for the interview, you might want to reintroduce yourself, to say again that you are an occupational therapist, and to briefly describe your role in the setting. You should then explain the purpose of the interview and the types of questions that you will be asking.

Body

The body is the exploration and development phase of the interview, the time when you and the client are actively constructing the client's story. Although specific interview procedures often provide a recommended sequence of questions, it is a good idea to enter into this phase of the interview with relatively general and neutral questions that allow you to begin to sketch the background of the story. Because you are interested in a client's occupations, you might begin by asking how the client spends his or her time on a typical day. Such a broad question tends to be nonthreatening but allows you to begin to develop a picture of the client's roles. Subsequent questions serve to fill in the details. Some clients are very forthcoming and are able to relate their stories easily; others will need much support and structure. It is during this phase that you will call on your skills in listening, attending, responding, and questioning.

Closure

Toward the end of the interview, you will need to begin to put closure on the session. It is important not to end the interview abruptly. Make sure that you allow sufficient time to summarize information, identify important themes in the client's story, and address how you and the client will work together. This will often be the time when you and the client mutually begin to set goals for intervention. As the interview comes to an end, you should let the client know what the next steps will be and when you will see the client again. You might set a time for your next appointment. You should also thank the client for sharing his or her story with you.

OCCUPATIONAL THERAPY INTERVIEWS

Over the past two decades, a variety of interviews have been developed for use with both children and adults. The interviews that are briefly reviewed next all provide methods of collecting information directly from the intended service recipient or client. There are also interviews that allow you to collect data from other informants, often caregivers or parents. For example, the Play History (Behnke & Fetkovich, 1984) collects information from a parent on a child's participation in play. Interviews that collect data from informants other than the intended service recipient are not described here but are reviewed elsewhere throughout the book. All of the interviews reviewed here can assist you in developing an occupational profile of the client and have demonstrated at least preliminary evidence of reliability and validity.

Interviews for Use with Children and Adolescents

The School Setting Interview

The School Setting Interview (SSI) (Hemmingsson, Egilson, Hoffman & Kielhofner, 2005) is a collaborative interview that allows children and adolescents with disabilities (including physical, developmental, and emotional/behavioral disabilities) to describe the impact of the environment on their functioning in multiple school settings (e.g., classroom, playground, gymnasium, corridors) and to identify any needs for accommodations. Appropriate for students from about age 9 years through high school, the SSI requires about 40 minutes to administer. The SSI was originally developed in Sweden and has been translated into English. Studies indicate that the SSI has good test-retest reliability (Hemmingsson & Borrell, 1996), demonstrates construct validity (Hemmingsson, Kottorp, & Bernspång, 2004), effectively measures the unmet needs for school environment accommodations of students with disabilities (Borg & Nålsén, 2003), and can be used to examine

student-environment fit in school settings (Hemmingsson & Borrell, 1996, 2000).

Adolescent Role Assessment

The Adolescent Role Assessment (ARA) (Black, 1976) is an occupational therapy interview that is specifically targeted for adolescents. The ARA is a semistructured interview procedure that gathers information on the adolescent's occupational role involvement over time and across domains. The 21 questions of the ARA cover six areas: childhood play, socialization within the family, school functioning, socialization with peers, occupational choice, and anticipated adult work. Early research found that the ARA had acceptable test-retest reliability, and scores on the ARA were found to discriminate between psychiatrically hospitalized adolescents and nonhospitalized adolescents (Black, 1982). A recent study that sought to explore the ARA's usefulness as a measure of adolescent career adaptability (Huebner, Emery, & Shordike, 2002) found that the internal consistency of the ARA was low. However, factors that were identified through factor analysis (developing aspirations, self-efficacy, interpersonal competencies, and autonomy) were consistent with career adaptability literature, and these factors were found to differentiate between low- and high-scoring adolescents. Given the paucity of interview procedures specifically targeted for adolescents, further development and refinement of the ARA and similar interviews should be a priority.

Interviews for Use with Adolescents and Adults

The Occupational Circumstances Assessment Interview and Rating Scale

The newest version of the Occupational Circumstances Assessment Interview and Rating Scale (OCAIRS) (Forsyth, Deshpande et al., 2005), a revision of the original OCAIRS developed by Kaplan and Kielhofner (1989), provides therapists with a method for gathering data on a client's occupational adaptation. Three semistructured interview formats targeted to the needs of different client groups (physical disability, mental health, and forensic mental health) are administered and clients are then rated on 12 items using a four-point rating scale. The items cover the client's personal causation, values and goals, interests, roles, habits, skills, physical and social environments, and readiness for change. The OCAIRS can be used with adolescent and adult clients with a variety of disabilities and requires about an hour to administer and rate.

Studies have shown the revised OCAIRS to have acceptable internal consistency and excellent interrater reliability (Haglund, Thorell & Walinder, 1998a; Lai, Haglund, & Kielhofner, 1999). OCAIRS scores also have been shown to discriminate between clients who need

occupational therapy intervention and those who do not and between those with different severities of psychiatric disorder (Haglund et al., 1998a, 1998b).

The Occupational Performance History Interview— Second Version

The Occupational Performance History Interview— Second Version (OPHI-II) (Kielhofner, Mallinson, et al., 2004) is a historical interview that gathers information about a client's occupational adaptation over time and can be used with adolescents and adults in a variety of settings. The OPHI-II consists of three parts: (1) a semistructured interview concerning a client's occupational life history; (2) three rating scales that quantify a client's occupational identity, occupational competence, and the impact of environment; and (3) a life history narrative with a narrative slope. The flexible interview format is designed to gather information in five thematic areas: (1) activity/occupational choices, (2) critical life events, (3) daily routines, (4) occupational roles, and (5) the environment. The three ratings scales provide a measure of (1) a client's interests, values, and confidence; (2) a client's ability to sustain satisfying occupational participation; and (3) the impact of the environment on a client's occupational life. The life history narrative and slope provide both a qualitative and visual description of the client's history. The OPHI-II can be administered in about an hour.

Validity of the original OPHI was examined in studies of individuals with physical and psychiatric disabilities (Henry, 1994; Lynch & Bridle, 1993; Mauras-Nelson & Oakley, 1996). An international study of the OPHI-II (using six different language versions) provided evidence of the internal consistency and construct validity of the three rating scales of the OPHI-II (Kielhofner, Mallinson, Forsyth, & Lai, 2001). Therapists can also use the client's ratings to obtain instantaneous interval client measures using a paper-and-pencil keyform as a way to document client function, monitor progress, and track change for outcome evaluation (Kielhofner, Dobria, Forsyth, & Basu, 2005).

The OPHI-II has been used in many settings with many types of clients, including clients transitioning to powered mobility (Buning, Angelo, & Schmeler, 2001), people with chronic fatigue syndrome (Gray & Fossey, 2003), clients in forensic psychiatric placements (Farnworth, Nikitin, & Fossey, 2004), homeless adolescent mothers (Levin & Helfrich, 2004), and people with HIV/AIDS (Braveman & Helfrich, 2001; Kielhofner, Braveman, et al., 2004). Therapists and clients report that the OPHI-II interview is a good opportunity to build rapport and is helpful when setting goals and planning the intervention, and clients often use the narrative slope as a motivational tool (Apte, Kielhofner, Paul-Ward, & Braveman, 2005).

The Worker Role Interview

The Worker Role Interview (WRI) is a semistructured interview that gathers data on psychosocial and environmental factors related to work and is appropriate to use with any individual whose disability has had an impact on their participation in work (Braveman et al., 2005). The WRI includes a set of recommended questions (including an interview format for clients with chronic disabilities, an interview format for those with recent injuries or disabilities, and an interview that combines WRI and OCAIRS questions) that are used to gather information in order to rate clients on 16-items using a four-point rating scale. The items form six subscales that reflect the worker's sense of personal causation, values, interests, roles, and habits related to work, as well as the influence of the environment. Studies indicate that therapists use the WRI in a consistent manner (good interrater reliability) and items represent the construct of ability to return to work (construct validity) (Biernacki, 1993; Forsyth et al., 2006; Velozo et al., 1999). Research conducted on WRI translations in other languages demonstrates the instrument's validity across other cultures (Fenger & Kramer, 2007; Haglund, Karlsson, Kielhofner, & Shei Lai, 1997), and one study using the Swedish translation found that certain items on the WRI predicted success for return to work (Ekbladh, Haglund, & Thorell, 2004).

The Work Environment Impact Scale

The Work Environment Impact Scale (WEIS) (Corner, Kielhofner, & Olson, 1998) is a semistructured interview and rating scale designed to examine how individuals with disabilities experience the work environment. The WEIS is intended for use with individuals who are currently working or are actively anticipating returning to a specific job or type of work. The WEIS asks questions regarding work environment factors such as space, social supports, temporal demands, objects used, and job functions, and the scale items reflect the extent to which environmental factors affect performance, satisfaction, and physical, social, and emotional well-being of the worker. Studies of the WEIS provide evidence of its construct validity and internal consistency (Corner, Kielhofner, & Lin, 1997; Kielhofner, et al., 1999).

The Canadian Occupational Performance Measure

The Canadian Occupational Performance Measure (COPM) (Law et al., 1998) is a client-centered semistructured interview procedure designed to measure a client's perceptions of his occupational performance over time. During an initial evaluation, the therapist interviews the client about his or her functioning in the areas of self-care, productivity, and leisure. The client is asked to identify any activities that are difficult to do in each area and to indicate how important it is to be able to do those activ-ities. Finally, the client is asked to identify his or her five most important problems and to rate his or her performance and level of satisfaction in these activities. The client rates the importance of the activity to the client, the quality of the client's performance, and the client's level of satisfaction using similar 10-point scales. The specific focus of the COPM on client-identified problems is intended to facilitate collaborative goal setting between the therapist and client. The COPM can also be used for reevaluation and to detect changes in the client's perceptions over time; thus, it has utility as an outcome measure (Law et al., 1998).

Across multiple studies, the COPM has been shown to have good test-retest reliability (Carswell et al., 2004; Law et al., 1998). Other studies have provided evidence of concurrent and construct validity of the COPM (Carpenter, Baker & Tyldesley, 2001; McColl, Paterson, Davies, Doubt, & Law, 2000). Studies that use the COPM as an outcome measure indicate that the COPM is sensitive to change following rehabilitation interventions (Corr & Wilmer, 2003; Lewis & Jones, 2001) while also being clinically useful and meaningful (Carswell et al., 2004).

ADJUNCTS TO INTERVIEWS: PAPER-AND-PENCIL SELF-REPORT MEASURES

In addition to interviewing, paper-and-pencil self-report measures can be a useful method of obtaining information from the client. Self-report measures include surveys, forms, and checklists that the client completes. Sometimes, a client can complete the form or checklist on his or her own, making this a convenient way to obtain information. More often, however, you should be present when the client is completing the measure, to ensure that the client comprehends what is being asked and is responding appropriately. Just as with interviews, self-report measures might not be appropriate for all clients.

In practice, self-report measures should not be used to substitute for a face-to-face interview with the client. They can be a helpful adjunct, however, because they tend to gather detailed information on a specific topic, such as time use or interest patterns. They are most useful when used in conjunction with an interview. Once a client has completed a self-report measure, the client and therapist should review the form together. Self-report measures help to focus the discussion around a particular topic or issue.

Self-Report Measures for Children and Adolescents

The Pediatric Interest Profiles

The Pediatric Interest Profiles (PIPs) (Henry, 2000) are paper-and-pencil surveys of play and leisure interests that are designed to be used with children and adolescents.

The three versions of the PIPs include the Kid Play Profile (KPP), for children ages 6 to 9 years; the Preteen Play Profile (PPP), for children 9 to 12 years; and the Adolescent Leisure Interest Profile (ALIP), for adolescents ages 12 to 21 years. Each version asked the youth to report his or her interest and/or participation in a variety of age-appropriate leisure activities and to indicate his or her feelings of enjoyment and competence in the activities. The PIPs also asked whether the youth does the activities alone or with others. The Kid and Preteen versions of the PIPs use pictorial representations of play activities. Total scores for the three versions of the PIPs have acceptable test-retest reliability (Henry, 2000). In addition, scores on the ALIP have been found to discriminate between adolescents with and without disabilities (Henry, 1998).

The Children's Assessment of Participation and Enjoyment and the Preferences for Activities of Children

The Children's Assessment of Participation and Enjoyment (CAPE) (King, et al., 2004) is a two-part self-report measure that gathers information on children's participation in everyday activities outside of mandated school activities. The CAPE is intended for children ages 6 years and up. In Phase 1, the child (or child and parent) indicates how often he or she has done a variety of activities in the past four months. In Phase 2, a practitioner interviews the child about the activities in which the child participates, regarding enjoyment in the activities and where and with whom activities are done. As in the PIPs, activity items are represented pictorially. The Preferences for Activities of Children (PAC) (King et al., 2004) examines a child's preferences for activities. The child sorts 50 activity cards, indicating whether she would "really like to," "sort of like to," or "not like to" do each activity. The PAC and the CAPE can be used together or separately. The CAPE/PAC manual reports evidence of the test-retest reliability, internal consistency, and correlations among the CAPE participation intensity scores and among the PAC preference scores (King et al., 2004). In one study, the CAPE was completed with 427 children between the ages of 6 and 14 years with physical disabilities to assess participation in nonschool activities (Law et al., 2004). Low to moderate, but significant, correlations were found between a child's sense of competence and the types of activities the child both prefers and enjoys, and boys and girls were found to have significantly different levels of participation intensity, preference, and enjoyment for certain activities (e.g., social activities versus active physical activities) (King et al., 2007).

Child Occupational Self-Assessment

Modeled after the Occupational Self-Assessment (see the section entitled "Self-Report Measures for Adults"), the 25 items of the Child Occupational Self-Assessment (COSA) (Keller, Kafkes, Basu, Federico, & Kielhofner,

2005) cover a range of everyday activities, including self-care, school tasks, social activities, and family-related activities, that children and youths rate through self-report. Young clients reflect on how competent they feel doing each activity and how important each activity is to them (Figure 34.2). Targeted to children ages 8–12 years, the COSA has also been used successfully with youth up to age 17 years (Keller, Kafkes, & Kielhofner, 2005; Keller & Kielhofner, 2005). Visual cues such as smile faces and stars support children and youths in completing the self-assessment, and a variety of modifications can be made without affecting the reliability of the rating scales (Keller & Kielhofner, 2005). Research has demonstrated that the COSA's two rating scales (competence and value) can be used in a consistent and valid manner and that the items represent a valid construct of children's and youth's occupational competence and value (importance) for occupations (Keller et al., 2005; Keller & Kielhofner, 2005).

Perceived Efficacy and Goal Setting System

The Perceived Efficacy and Goal Setting System (PEGS) (Missiuna, Pollock, & Law, 2004) provides young children

FIGURE 34.2 By completing a self-report assessment, a young client has an opportunity to talk about the things he likes doing and identify any trouble he is having doing activities that are important to him.

with an opportunity to report their efficacy for performing occupations that involve gross and fine motor tasks. Based on the All About Me scale (Missiuna, 1998), the PEGS includes pictures representing 24 activities, 12 in each subscale of fine motor and gross motor activities (such as "bicycle" and "doing up buttons"). Two related pictures represent each task, the images depicting a child performing an activity in a more competent or less competent manner. Children indicate which image is more like them and whether that image is a lot or a little like their performance. Then, to identify goals for therapy, the child then prioritizes tasks that he or she has reported having difficulty performing.

The PEGS items were found to discriminate between children with motor difficulties and those without and was moderately correlated with other standardized motor assessments (Missiuna, 1998), indicating that the instrument has discriminative and construct validity. Parent and teacher PEGS ratings were significantly correlated with the School Functional Assessment (Coster, Deeney, Haltiwanger, & Haley, 1998), but children's scores were not (Missiuna, Pollock, Law, Walter, & Cavey, 2006). Internal consistency was acceptable (Missiuna et al., 2006), subscale reliability was good for both subscales, and test-retest reliability over two weeks for one group of children was also good (Missiuna, 1998). While children using the PEGS rated themselves as more competent compared to parent or teacher ratings, parents, teachers, and children often agreed which tasks were more or less difficult for each child (Missiuna & Pollock, 2000; Missiuna et al., 2006). Children were also found to use the goal-setting processes effectively over time; after two weeks, 92% of children selected between two and four of the same goals (Missiuna et al., 2006).

Play Skills Self Report Questionnaire

The Play Skills Self Report Questionnaire (PSSRQ) (Sturgess, 2007) initially developed and reported as the Playform (Sturgess & Ziviani, 1995, 1996), is designed for children aged from 5 to 10 years and includes a Parent Version. Continued research on the Playform (Sturgess, 1997, 2003), some yet to be published, has resulted in modifications. The PSSRQ now consists of a booklet containing a question and a supporting line drawing on each page. The child rates himself or herself on 30 play skills that incorporate play alone, play in a dyad, play in a group, pretend play, rough and tumble play, games with rules, collecting things, and others. Children respond to questions such as "Are you good at making up ideas for pretend games?" and "Are you good at running and climbing and moving when you play?" using four different size stars that symbolize "not good," "OK," "good," and "very good." Parent and child versions have the same graphic to assist in ensuring that both are referring to a similar stimulus and enhance reliability of answers.

Content validity for the items and validity for the structure was established through a series of pilot studies with expert clinicians, parents, and children. Data have been analyzed from the responses of 176 typically developing children and their parents, which provide preliminary normative and comparative data (Sturgess, 2007). No total score is generated, as each item is unique, and no factor structure was found. The PSSRQ is designed to be used with one child over time; can be used to develop goals for intervention; and may also be valuable in health promotion, parent education, and other situations in which play is recognized as having a positive influence on healthy behaviors.

Self-Reports for Use with Parents of Children and Adolescents

Children Helping Out: Responsibilities, Expectations, and Supports (CHORES) (Dunn, 2004) is a parent self-report that was developed to assess children's participation in household tasks and changes in the amount of assistance needed to participate. The CHORES consists of 34 items that represent typical household tasks; 13 items form a self-care subscale (such as "picks up own bedroom" and "makes self a snack"), and 21 items form a family care subscale (such as "sets or clears the table," "cares for younger siblings," and "feeds pet(s)"). For each item, parents indicate whether the child participates in the household task and describes that participation using a two-part scale. If the parent reports that the child does not do the task, the parent indicates whether the child is not expected to do the task or the child cannot perform the task. If the parent reports that the child engages in the task, a five-point scale is used to report the level of assistance and supervision the child needs. At the end of the survey, parents rate how important their child's involvement in household tasks is to them and their level of satisfaction with their child's participation.

CHORES has been used with children and adolescents with and without disabilities who have a variety of cultural backgrounds (Dunn, 2004). The CHORES performance and assistance scores show adequate variance to identify differences in participation in household tasks, and parent's reports were found to remain stable from test to retest (Dunn, 2004). There is evidence for discriminate and face validity (Dunn, 2004).

Self-Report Measures for Adults

Interest Checklists

Interest checklists are among the most commonly used self-report measures. Interest checklists are used to tap a client's level of interest in a range of activities, most often leisure activities. Age-targeted measures of interest in activities are likely to yield more relevant data than a general measure, because leisure interests vary widely across the age span. Interest checklists are useful in identifying

problems related to leisure and for identifying potential activities to use in treatment.

One of the oldest checklists is the NPI interest checklist (Matsutsuyu, 1969). The NPI interest checklist contains 80 activity items, grouped into five categories: activities of daily living, manual skills, cultural and educational activities, physical sports, and social and recreational activities. In completing the checklist, the client indicates strong, casual, or no interest in the activity (Rogers, 1988). The original NPI interest checklist was found to have acceptable test-retest reliability and to show evidence of construct and predictive validity (Barris et al., 1986; Ebb, Coster, & Duncombe, 1989; Henry, 1994; Weinstein, 1979). Kielhofner and Neville (1983) modified the NPI interest checklist to include questions concerning changes in activity preferences over time and the desire to participate in interests in the future.

Gregory (1983) described two self-report measures of activity involvement that are specifically designed for older adults. Total scores on both the Activity Index, which taps activity interest and participation, and the Meaningfulness of Activity Scale, which taps feelings of enjoyment, autonomy, and competence relative to activities, demonstrated good test-retest reliability with small pilot samples. Scores on both measures were also correlated positively with a measure of life satisfaction.

The Role Checklist

The Role Checklist (RC) (Oakley, Kielhofner, Barris, & Reichler, 1986) is a two-part, paper-and-pencil inventory of ten occupational roles, including worker, student, family member, homemaker, caregiver, volunteer, and hobbyist. The first part of the RC examines a client's past, present, and future intentions related to performance of each role. The second part examines the value assigned to each role by the client. The RC has been translated into 10 languages, and a Spanish translation has been determined to have content validity (Colon & Haertlein, 2002). Studies have indicated that the RC has good test-retest reliability (Barris, Oakley, & Kielhofer, 1988), is sensitive to role changes (Hallett, Zasler, Maurer, & Cash, 1994), and discriminates between adults without disabilities and those with psychiatric or physical disabilities (Dickerson, 1999). The RC has also been successfully used as an outcome assessment tool in studying the efficacy of occupational therapy interventions (Corr, Phillips & Walker, 2004; Corr & Wilmer, 2003; Schindler, Laguardia, Melchiorre, & Bailey, 2004).

Occupational Self-Assessment

The Occupational Self-Assessment (OSA) (Baron, Kielhofner, Iyenger, Goldhammer, & Wolenski, 2002) is a self-report measure designed to gather data on a client's perception of his or her occupational competence (21 items) and the impact of the environment on her

functioning (eight items). The OSA also asks clients to indicate the importance of specific areas of functioning and to identify priorities for change, making it particularly useful to use in conjunction with an interview. The OSA can be used as an initial assessment and as a follow-up or outcome measure that captures client-reported change in functioning. A series of studies, involving 1,000 international clients, have been conducted on the OSA to refine the rating scales, increase the sensitivity of the instrument, and confirm the validity of the items on the assessment (Kielhofner & Forsyth, 2001; Kielhofner, Forsyth, Kramer & Iyenger, 2007). An analysis of OSA time 1 and time 2 assessment results confirmed that items on the competence scale, the competence rating scale, and the values rating scale remained stable over time, allowing the creation of the OSA paper keyforms (Kielhofner, Forsyth, Dobria, & Kramer, 2007). Similar to the OPHI-II keyforms, the OSA keyforms allow therapists to generate instantaneous client measures that can be used to document change.

CONCLUSION

In addition to providing information about a client's functioning in specific occupations, interviews are among the most useful strategies available to practitioners both to better understand the client's perspective of his or her situation and to enhance the working relationship with the client. Each of the interviews and self-report measures discussed in this chapter has unique characteristics. Practitioners should choose the combination of interview and other assessments that best fits the needs of their clients and setting.

Analyzing Occupations and Activity

ELIZABETH BLESEDELL CREPEAU AND BARBARA A. BOYT SCHELL

Learning Objectives

After reading this chapter, you will be able to:

1. Describe approaches to analyzing occupations and activities in occupational therapy.
2. Describe the similarities and difference between activity analysis and occupational analysis.
3. Understand how occupational performance is the result of skilled transactions between the person and the performance context.
4. Define occupational orchestration.
5. Analyze activity in general and as experienced by an individual.
6. Describe how grading and adapting activities can be used to meet the needs of clients.

Think about all the things you have or will do today, as you go about your daily rounds. Perhaps you started your day with a bath or shower. Did you do that? Or do you prefer to bathe at night? Or, are you someone who prefers to bathe every other day? If you did bathe or shower, did you wash your hair? If you washed your hair, did you shampoo it once or twice? Did you apply a conditioner? Did you wash your hair before you washed the rest of your body or after? Were you standing in a shower, sitting in a tub, or leaning over a sink? How hot was the water? Did your arms get tired? Did you dry your hair with a towel or just comb it and let it dry itself? Or did you style your hair with a hair dryer? Did you use a pick, comb, or brush? What physical functions would you say are critical to doing your hair? What mental functions? What features of the setting or context are important to you? Do you think the same things are important for all people? Answering questions such as these are part of the daily thinking processes that occupational therapy practitioners consider when they go about planning and implementing care for their patients and clients. Whether the attention is on self-maintenance activities, such as bathing and hair care, or on work activities, such as driving a bull-dozer, practitioners require systematic frameworks to understand exactly what each person wants or needs to do. Application of

these systematic frameworks is called **occupational analysis and activity analysis**.

Occupational therapy practitioners analyze activities to understand their component parts, their possible meaning to clients, and their therapeutic potential. Practitioners analyze the occupations of clients to gain an appreciation of specific performance strengths and potential problems clients are encountering. The analysis is used to design therapeutic intervention to enable clients to engage or re-engage in those occupations that have particular meaning and value. Practitioners also analyze how clients orchestrate their occupations across a day, week, and longer periods of time. **Occupational orchestration** reflects the capacity of individuals to enact their occupations on a daily basis to meet both their own needs and those in their social world. Orchestration, a musical term, implies a rhythmic, harmonious composition of daily life that has habitual or routine components but is also responsive to changes in demands from day-to-day (Larson, 2000). Occupational therapy intervention is based on engaging clients in meaningful occupations to enable or improve their ability to meet their goals and participate in daily life. The occupations may be seemingly minor, such as the morning shower, or the orchestration of the complex array of daily occupations necessary to live a full and satisfying life, such as managing the pastoral care committee of the church while working full time and caring for the family. Consequently, the analytic processes practitioners bring to their work are at the core of occupational therapy practice. This chapter describes these processes and links them to professional reasoning as it occurs throughout the therapeutic process.

TWO PERSPECTIVES ON ANALYSIS: OCCUPATION AND ACTIVITY

Occupational therapy practitioners approach the process of activity analysis from two different perspectives, occupational analysis and activity analysis. In the first approach, practitioners are concerned with understanding the specific situation of the client, and therefore must understand the specific **occupation**s the person wants or needs to do in the actual context in which these occupations are performed. We refer to this as occupational analysis, because the term occupation connotes personally experienced performance (Pierce, 2001). As discussed in the AOTA Practice Framework, 2nd Ed. (AOTA, 2007) this is a customized approach that is embedded in the entire occupational therapy process. Occupational analysis attends carefully to the specific details of the person's occupations within his or her own context. Indeed, it is this customized approach that differentiates the occupational therapy perspective from that of many other professions who do activity analysis, such as vocational educators and industrial engineers. In the bathing example provided in the opening paragraph, your answers to how you specifically performed the process of bathing represents part of an occupational analysis, in

that it helps describe the way that you actually do a particular occupation in your own life. See Box 35.1 for the rationale for the specific terms we are using in this chapter.

The second approach is commonly called activity analysis. In activity analysis, the practitioner considers an activity in the abstract, as it might typically be done within a given culture (Pierce, 2001). Practitioners do this sort of activity analysis for at least two reasons. First, the practitioner may wish to anticipate possible areas of concern in working with clients with different kinds of health conditions or concerns. Secondly, practitioners often need to generate **purposeful activities**, goal-directed behaviors leading to an occupation, (AOTA, 2007) which can be usefully designed or graded to help a client develop, recover from an impairment, or learn an adaptive approach. For instance, if a practitioner thinks about what is typically involved in bathing or showering for many people in the United States, then he or she might be able to anticipate possible problems for someone with a partial paralysis or difficulty remembering how to sequence activities. Alternatively, while at a toy store or hardware store, the practitioner might notice toys or objects that lend themselves to helping individuals develop or improve in various skills or bodily capacities, or which require particular kinds of problem solving. Having these ideas in the practitioner mental "toolbox" makes it easier to generate therapy possibilities for working with clients. Such consideration of activity possibilities is a *decontextualized approach,* because it is an abstract idea of what the practitioner thinks typically occurs. It is not what any one particular person actually experiences.

To summarize, the term **activity** is used in this chapter to represent an *abstract idea* about kinds of things individuals do and the way they typically do them in a given culture (Pierce, 2001). The term occupation(s) is used to denote the *personal activities* that individuals choose to engage in, and the ways in which each individual actually experiences them. Practitioners must be able to analyze both the abstract idea of an activity within a culture, as well as the actual occupations as they are performed by particular individuals. These perspectives can also be applied to groups of people (such as members of a choir or workers in a plant), organizations (such as the local recreation center), and populations (such as middle school students or elders in a community). This chapter will focus primarily on analysis of activity and occupation at the individual level, as the application to groups builds on these core analytic approaches. Other chapters later in the text provide illustrations of how occupational analysis can be used in relation to groups, organizations and populations.

PERFORMANCE CONTEXTS AND ENVIRONMENTS

Occupational performance is by nature embedded within a social and physical environment, situated in a performance context (AOTA, 2007; Dunn, Brown, & Youngstrom,

> ## BOX 35.1　WORDS MATTER: DEFINING ACTIVITY AND OCCUPATION
>
> Words matter because they shape the way we think and the meanings we ascribe to their underlying concepts (Hymes, 1972). Occupational therapy, like many other professions and disciplines, engages in ongoing debates about the meaning of specific terms as they relate to the profession. This debate can become confusing, as professional jargon may or may not parallel the way that the same words are used in everyday speech (Reed, 2005). Occupation and activity are two such words with everyday meanings and specialized professional meanings. Because these terms are so central to our field, many scholars have attempted to articulate precise meanings. The abundance of these definitions can be confusing, especially to occupational therapy students who are new to the field and seeking to understand it.
>
> Definitions of *occupation* typically include a combination of the following concepts[a]:
>
> - Personally experienced and goal directed
> - Reflects culture and cultural values
> - Provides meaning
> - Involves multiple tasks
> - Provides organization and structure to living
> - Meets needs of the individual and others in the social world
> - Fills time
> - Uses abilities and skills
> - May have a physical and/or mental component
> - Is recognized by the culture
> - Provides pleasure and enjoyment
> - Contributes to family and broader community
> - Contributes to health and well-being
> - Aligns with development of the individual
>
> Definitions of *activity* typically share a mix of the core concepts listed below. Activity is frequently modified with
>
> terms such as *purposeful, occupational,* or *functional* to give it more specific meaning. In these cases the term activity itself is not defined but assumed to be common knowledge. The core concepts[b] for most definitions of activity include the following:
>
> - Small units of behavior
> - Use of objects
> - Action
> - May or may not produce an object
> - Goal directed
> - Required for development, maturation and use of sensory-perceptual, motor, social, psychological, and intellectual functions
>
> In contrast, Pierce has defined activity as
>
> . . . an idea held in the minds of persons and in their shared cultural language. An activity is a culturally defined and general class of human actions . . . An activity is not experienced by a specific person; is not observable as an occurrence; and is not located in a fully existent temporal, spatial, and sociocultural context. (Pierce, 2001, p. 139)
>
> For the purpose of this chapter we have chosen to adopt Pierce's definition of activity because this definition enables us to make the distinction between the abstract ideas we have about a particular activity for activity analysis, for example swimming, versus the engagement in swimming as an occupation that is dependent on the way or ways a particular person swims and the meaning he or she ascribes to it. Consequently, throughout the chapter when you read *activity* you should remember that this reflects the abstract, decontextualized concept and *occupation* is the way a particular person enacts this activity in a specific context. In other chapters in this book you will find terminology used differently. You need to look behind the terminology to understand the intent of the authors in their word choice.
>
> [a]Compiled from: Christiansen, Baum, Bass-Haugen, 2005; Spear & Crepeau, 2003; Hinojosa & Kramer, 1997; Law, Polatakjo, Baptiste, & Townsend, 1997; Nelson & Jebson-Thomas, 2003; Clarke et al., 1991.
> [b]Compiled from: Allen, 1987; 2007; Cynkin, 1995; Hinojosa & Kramer, 1997; Llorens, 1986; Mosey, 1981; Reed, 2005; Trombly, 1995.

2003; Pierce, 2001). *Environment* includes the physical and social environments in which the client performs their occupations. *Context* includes the external physical, social, and cultural environments in which people function, as well as the internal or personal aspects, such as age, gender, motivation of the person. Additionally, occupations are

located in a temporal context, both in terms of the specific amount of time involved, as well as the history and projected future related to occupation. Finally, some occupations occur on virtual contexts, such as web-based blogs and spaces. Paralleling the distinction just made between activity and occupation, many aspects of the environment

and context can be considered in abstract or as the client actually experiences them.

Arenas and Settings

Lave (1988), an anthropologist, makes a distinction between the potential uses of environmental contexts and the ways people actually interact with them. She used the term **arena** to describe the places in which activities occur, such as a library, school, or hospital. In contrast, she used the word **setting** to describe those aspects of the arena to which the person attends. This distinction is useful in that it, once again, illustrates the twin ideas of actual experience versus abstract conceptualizations. For example, a library is an arena, and many of us conjure up an idea of what a library is. In fact, we may even think of a particular library. However, each individual will use the library in different ways and to construct different meanings from their experiences. A man entering the library with his young child will most likely go to the children's section to look at colorful picture or chapter books. He is likely to sit on a small chair or a pillow while reading to his child. Later, he may help the child select books to take home. In contrast, another person may go to the audio section to check out an audio-book to listen to while commuting to work. Thus, while the library as an arena remains the same, the library as a setting differs from person to person. Consequently, the distinction Lave makes between arena and setting is similar to the distinction made earlier between activity and occupation. Like activity, arena is an abstract idea, whereas settings are where occupational activities are actually done.

Roles: Social Constructions versus Personally Enacted

Role theory has had an influence on the development of theory within the profession. For instance, the Model of Human Occupation described in Chapter 44 uses role as a way of articulating how individuals see themselves and the multiple aspects of a person's life. The concept of role filters down into assessments such as the Role Checklist and Worker Role Interview (see Unit XVI for information on these and other examples). In sociological and psychological theories, roles are seen as social positions (Jackson, 1998a, Hagendorn, 2000). As Fisher noted in her Slagle lecture, "the role dimension pertains to the relationship between one's roles and the related collection of task performances that must unfold in a logical, timely, and socially appropriate manner. We must understand the person's perceived roles and any incongruities between his or her role behavior and the role behavior that is expected by society or desired by the person" (1998, p. 544). Thus roles can be thought of as normative models shaped by the culture. They help articulate expectations for what constitutes being a "good" mother, father, student, etc. and what people in these positions are supposed to do. Individuals within

roles may adopt these normative expectations or may interpret the expectations to fit their own values and beliefs.

Jackson (1998a, 1998b) argued that our concern should be on the occupations individuals engage in, not their roles because the concept of role is problematic from several perspectives. First, roles may overlap. For example, it is often impossible to distinguish a child's "student" role from their "friend" role. When someone is cooking, is it in their role as mother or father, church volunteer, or chef? In both instances, our concern is in the occupation, the person's ability to engage in the occupation, and the meaning they ascribe to it, not the role to which the occupation connects. Second, while the concept of role provides a shorthand way of understanding the occupational world of an individual, Jackson (1998a) argued that this approach is risky because inherent in the concept of role are the power issues embedded in many cultural models. For example, who decides what a "good mother" is? Who says the mother is the one to do the cooking for the family?

Still, role is not easy to ignore because it is such a widely held concept. For example, Trombly Latham (1995; 2008) uses role as an organizing construct, however she cautions that when considering role it should be from the definitional perspective of the individual, rather than the normative expectations of society. But how does one get to this definitional perspective except through understanding the occupations the individual attaches to a particular role? By focusing on occupations people engage in, we can see what they do, what the occupation means to them, how they feel about their performance, and how they organize their occupations to meet their needs and those of the people around them. Our analysis begins with occupation and may result, if needed, in clustering these occupations into the individual's personal definition of the occupations associated with their roles. Once again, we see the contrast between the abstract notion of role and the personally experienced situation of the individual, sometimes called **occupational role**.

Jackson's (1998a, 1998b) cautions about the use of role are important because it is easy to unconsciously slip into normative expectations or use one's personal experience to frame the expectations for others. As discussed earlier in Chapter 32, practitioners bring unarticulated personal assumptions to the therapy process. Consequently, we have chosen not to use role as an organizational construct for this chapter because we want to focus on those occupations that are most important to an individual regardless of what role or roles to which they might be assigned. Instead, we look at the orchestration of occupations as they are enfolded, and integrated in the course of daily life.

OCCUPATIONAL ANALYSIS AND MEANING

Over and over again practitioners need to remind themselves that meaning is individually constructed and inter-

preted and is central to human existence (Bruner, 1990; Frankl, 1959; Hasselkus, 2002; Peloquin, 2005, 2007). A practitioner is obligated to understand the meaning of occupations from the client's perspective. Using the library example discussed previously, it is possible if you talked to the father about the meaning of going to the library with his child that he might mention the pleasure he derives from instilling in his child the value and enjoyment of reading and the quiet time they share together. He might recall his childhood and the times he went to the library with one of his parents. Alternatively, he might explain that he never had the opportunity to go to the library with his father because his father had abandoned the family. The latter experience would create an entirely different meaning and motivational structure for this father–child dyad as they engage in this **co-occupation**.

As this example illustrates, the different experiences, values, and beliefs of clients make the interpretation of meaning a particularly complex aspect of practice. This challenge is exacerbated by potential cultural and socioeconomic differences between practitioners and their clients making it more challenging for practitioners to fully understand the experiences of their clients and the meanings they ascribe to their occupations (Crepeau, 1991; Kielhofner & Barrett, 1998; Payne, DeVol, & Smith, 2001) (See also Chapters 6 through 9 in this text which address culture, socioeconomics, place, and spirituality). It is the practitioner's responsibility to develop the therapeutic relationships that foster an understanding of clients and their world (Crepeau, 1991; Peloquin, 1995; see also Chapter 29 which addresses client-centered collaboration and Chapter 33 which addresses the therapeutic relationship). Activity analysis and occupational analysis are part of the tools that practitioners can use to achieve this understanding. Table 35.1 provides a quick reference to remind readers as to what concepts are tied to the person's subjective experience versus what terms are more related to practitioners' abstract understanding of typical demands.

ACTIVITY AND OCCUPATIONAL ANALYSIS IN PRACTICE

Occupational therapy practitioners draw on their education, knowledge of activities, and professional experience when analyzing activities (Neistadt, McAuley, Zecha, & Shannon, 1993). This analysis is so automatic that it is often ignored or unappreciated, becoming another aspect of the tacit nature of the reasoning process used by practitioners (Mattingly & Fleming, 1994; Schell & Cervero, 1993). Practitioners analyze activities from the perspective of practice theories to understand problems in performance and intervention strategies appropriate from that theoretical perspective. Their analysis is also based on access to particular activities and the degree to which they are willing to engage in trial and error or experimentation to understand activities more fully (Schell, 2007).

Studies that have attempted to make activity analysis an objective process have demonstrated that the number of variables is so great that the goal of objectivity would be exceedingly difficult to achieve (Llorens, 1986; Neistadt et al., 1993; Trombly, 1995). Adopting the distinction between activity analysis and occupational analysis renders this concern moot. If the outcome of activity analysis is to understand the *potential* demands of an activity, objectivity is not the goal. Rather, identifying the multiple skills typically required and the potential meanings the activity may have enables practitioners to have a deeper understanding of this activity in general.

In contrast to the abstract consideration of activities for their therapeutic implications, occupational analysis is a highly individualized process because it is embedded in the particular perspective of the person, the person's occupational performance, and the performance context. Occupational analysis occurs when attempting understand the person as an occupational being in concert with identifying occupational performance and barriers to effective performance (Coster, 1998; Fisher, 2001; Hocking, 2001; Polatajko, Mandich, & Martini, 2000; Trombly, 1995; Trombly Latham, 2008). Client-centered evaluation models examine the ability of a person to engage in a valued occupation and the transaction among actual performance, activity demands, and context (Law, 1998). Box 35.2 provides examples of the various degrees of focus that practitioner's use to consider occupations.

Both occupational and activity analysis are required for effective practice. By blending these analytic models, practitioners can gain an understanding of the particular ways in which clients relate to their occupations and can

BOX 35.2

OCCUPATIONAL SCALE: A QUESTION OF FOCUS

Just as there is little agreement in the field about the definition of activity, there is little agreement about the scope or scale of what actually constitutes an occupation. Hinojosa captured this dilemma eloquently when he shared his personal reflections about occupation:

> I am uncomfortable with the current trend in the profession to call everything we do as occupation. I personally cannot believe that brushing my teeth or being able to effectively use toilet paper in the bathroom is an occupation. I do believe that they are important purposeful activities. I have come to realize that the combination of these two activities is fundamental to complete personal hygiene occupations (Hinojosa, Kramer, Royeen & Luebben, 2003, p. 8).

Hinojosa's question could be restated as follows:

> Is an occupation a collection of tasks within a broad scope of one's life (cooking) or some of the sub-tasks within this category (making a meal) or even smaller units (preparing vegetables for the salad)?

Lens	Example: Cooking	Analytical Questions
Panoramic (Zoom Out) ↑↓	Making a meal	What does this person cook and why? In what settings do they cook (ie, home, community center, homeless shelter kitchen?) How often does the person cook? How does it overlap or enfold within other occupations (ie, is it important in their job, to their duties to their spouse or partner?) Can the person do the planning and organization necessary? Does the person have skills to prepare the food? Does the person get each part of the meal done in a timely manner? Is the quality of the result satisfactory to the person and significant others?
	Preparing a salad	Can the person get the salad ingredients from the refrigerator? Does the person remember to get all they need? Can the person use a knife safely with different ingredients? Can the person use a knife effectively with all the ingredients? Can the person get the salad to the table? Does the person season it to their own standards and that of those sharing the salad?
Close-Up (Zoom In)	Slicing a tomato	Can the person grasp the tomato? Does the person hold it too tightly or too loosely? Can the person hold the knife by the handle? Does the person know to hold the handle as opposed to the blade? Does the person position the knife relative to the tomato? Is the person at risk of being cut? Does the person cut the tomato in the desired shape? Do the tomato slices meet the person's own standards and that of others eating the salad?

OCCUPATIONAL SCALE: A QUESTION OF FOCUS   *Continued*

There is little agreement in the field on this issue with scholars proposing a variety of ways to nest the sub-units of occupations within the broader category. These include the following:

◆ Trombly Latham nests activities within tasks which constitute life roles (1995, 2008).
◆ Polatajko, Mandich, and Martini (2000) break down occupations into tasks which contain segments, units, and sub-units
◆ Baum and Christiansen (2005) start with roles, tasks, and actions
◆ Fisher considers the role dimensions of an individual's occupations and places tasks (what the person does)

within this category (1998), but notes the importance of starting with a person's goals

Our purpose here is to point out the lack of agreement and say that we have no solution to the problem. We just want you to recognize that there are varying ways to consider analyzing occupations. We borrow Crabtree's (1998) metaphor comparing the occupational therapy reasoning process to a camera lens. Sometimes we zoom out to see the big picture and sometimes we zoom in to capture the fine details. The depth and scope of analysis is directly related to the goals by the client for intervention and the reasoning process of the practitioner in responding to these goals.

---

then use their knowledge of activity and practice theories to harness those occupational activities for therapeutic purposes. This understanding is achieved through both forms of analysis. Table 35.2 on page 367 summarizes the questions addressed in both activity and occupational analysis. Box 35.3 shows how practitioners weave analysis of occupational performance throughout the therapy process. Box 35.4 lists some of ways that these analyses inform practice decisions.

ACTIVITY ANALYSIS

Activity analysis is a way of thinking about activities. Practitioners must perform quick analyses while working with clients. In addition, occupational therapy practitioners may also think about activities for their therapeutic potential, for instance by sizing up new games, cooking gadgets, and other objects or activities. Activity analysis addresses the typical demands of an

---

ANALYSIS OF OCCUPATIONAL PERFORMANCE

Occupational performance is the accomplishment of the selected occupation or activity resulting from the dynamic transaction among the client, the context and environment, and the activity. Evaluation of occupational performance involves

◆ Synthesizing information from the occupational profile to focus on specific areas of occupation and contexts that need to be addressed.
◆ Observing the client's performance in desired occupations and activities, noting effectiveness of the performance skills and performance patterns.
◆ Selecting and using specific assessments to measure performance skills and patterns as appropriate.

(AOTA, 2007, p. 21).

◆ Selecting assessments, as needed, to identify and measure more specifically contexts or environments, activity demands, and client factors that are influencing performance skills and performance patterns.
◆ Interpreting the assessment data to identify what supports performance and what hinders performance.
◆ Developing and refining hypotheses about the client's occupational performance strengths and limitations.
◆ Creating goals in collaboration with the client that address the desired outcomes.
◆ Determining procedures to measure the outcomes of intervention.
◆ Delineating potential intervention approach or approaches based on best practice and available evidence.

<table>
<tr><td colspan="2">

BOX 35.4   **WAYS ACTIVITY AND OCCUPATIONAL ANALYSIS INFORM PRACTICE**

</td></tr>
<tr><td>

Practitioners analyze activity in the abstract for the following reasons:

◆ Understand the therapeutic potential of a wide range of activities
◆ Identify activities which lend themselves to
   a. Improving client performance through acquiring new skills or learning adaptive strategies
   b. Restoring a skill or client factor which impacts performance skills
   c. Prevention of future problems by changing or adapting activity demands or performance context

</td><td>

Practitioners analyze the occupations of their clients to

◆ Evaluate quality of current performance in valued occupations and the effectiveness of their capacity to orchestrate their occupations.
◆ Determine impact of personal factors (including health condition) on current performance.
◆ Determine impact of contextual factors on current performance
◆ Prognosticate future performance in identified contexts
◆ Identify ways to grade or adapt occupations for foster improved performance

</td></tr>
</table>

activity, the range of skills involved in its performance, and the various cultural meanings that might be ascribed to it. The goal of activity analysis is to understand as much as possible about an activity, including the particular skills required to do it competently and its relation to participation in the world at large (Cynkin, 1995). It is this knowledge of activities, their properties, and their potential cultural meanings that sensitizes practitioners to the occupations of their clients and helps practitioners know which particular activities to suggest to their clients. Through activity analysis practitioners gain an understanding of the therapeutic potential of a wide range of activities. Because practitioners are constantly analyzing activities, they develop the capacity to quickly analyze a wide range of activities for their therapeutic or evaluation potential. For example, in the vignette that opens Chapter 32, Terry, the occupational therapist, had to very quickly identify alternate ways to evaluate Mrs. Munro's safety. The therapist had planned to use observation of self-care to check out how safely Mrs. Munro moved and if she remembered and sequenced appropriately. Since Mrs. Munro had already done her self-care, Terry quickly found a relevant cleaning task that would essentially demand similar skills based on cognition and mobility.

Activity Analysis Format

The activity analysis format is based on the organization of the *Occupational Therapy Practice Framework* (AOTA, 2002) and the subsequent edition (AOTA, 2007) as well as information from various chapters within this text. The *Occupational Therapy Practice Framework* is designed to reflect the current practice of occupational therapy and its concern for occupational engagement to support health and participation of people in our society. Activity analy-

sis focuses on the identification of activity demands and performance skills. Activity demands include aspects of the activity such as the objects typically used, the space and social demands of the activity. The analysis format also includes consideration of the typically required body structures and functions as they relate to the skills often used in the activity. Also included in the analysis are the expected skills which represent the interface between the person and the performance setting.

As part of activity analysis, practitioners may consider the utility of the activity as viewed through different theoretical lenses. For instance, a therapist who is working with a population of people with biomechanically related impairments (i.e., hand injuries, back injuries) may analyze activities in terms of the typical strength, range of motion, and endurance required to complete them. Alternatively, someone who is concerned about supporting interpersonal skills in clients with mental illness may look primarily at the complexity of social interactions which the activity typically demands (Davidson, 2003). By using the principles of a particular practice theory, occupational therapy practitioners analyze activities as they think about performance strengths and problems addressed by the particular theory. The potential therapeutic intervention should be consistent with the theory and will likely entail the grading and adaptation of the occupations chosen by the client. Table 35.2 presents a format for analysis of activities.

OCCUPATIONAL ANALYSIS

In contrast to activity analysis, occupational analysis *places the person in the foreground* by taking into account the particular person's life experiences, values, interests,

goals. Occupational analysis attends to their actual body functions and structures and considers the actual performance arena, including physical and social contexts along with the demands of the occupation itself. These considerations shape the practitioner's efforts to help the person reach his or her goals through carefully designed evaluation and intervention. Practitioners vary the scope of the occupational analysis depending on the nature of the client concerns, health problem and the nature of the intervention setting.

As discussed earlier, occupational analysis may be focused on a particular occupation, such as using a keyboard on the computer or brushing one's teeth, or it may be focused on a broader scope of how individuals orchestrate numerous aspects of occupational performance into daily life, such as being an effective worker. We illustrate two approaches to analyzing occupations, which vary by the scope of the client's concerns.

◆ **Occupational analysis:** Analysis of occupations parallels activity analysis, with the important difference that it is examining an actual occupation that the person does in his or her own unique way. Questions used for occupational analysis are found in the last column of Table 35.2.

◆ **Analysis of occupational orchestration:** Table 35.3 illustrates ways to consider how individuals engage and manage their multiple occupations.

OCCUPATION AS THERAPY

The careful use of occupations for therapeutic change is what makes occupational therapy unique. Intervention strategies typically involve changing occupations in ways that either facilitate development or improvement in desired performance or allow for participation in spite of limitations. Inherent in these approaches is attention to developing and maintaining the client's motivation for change. Common approaches are **grading**, **scaffolding**, **fading**, **coaching**, and **adaptation** or **modification**. The ability to use these approaches for a wide variety of activities/occupations and from various theoretical perspectives is a core skill for occupational therapy practitioners.

Grading

The grading of an occupation involves sequentially increasing its demands to stimulate the person's function or conversely, reducing the occupational demands to respond to client difficulties in performance. Often, practitioners grade occupations to improve the client's underlying capacities and skills (Fisher, 2001). Depending on the nature of the client's performance problems and the practice theory or theories selected by the prac-

titioner to address these problems, the particular way of grading will vary. For example, a practitioner may grade the occupation from a sensory integrative theory perspective when working with a child who wants to ride a two-wheeled bicycle but who is unsuccessful at balancing sufficiently. The practitioner may provide intervention for the child a sensory-enriched environment (suspended equipment, large therapy balls, climbing equipment) designed to evoke active exploration on the part of the child. The available sensory equipment provides a variety of vestibular, tactile, and proprioceptive stimuli for creating sensory experiences that require postural control, including balance. The child initiates the desired occupation within the sensory enriched environment and, based on careful observation of the child's reaction, the practitioner may reduce or increase the balance demands of the occupation to provide the "just right challenge" for the child. The child can learn to use his or her body in new and novel ways so that increasingly complex possibilities for physical engagement emerge (see Chapter 59). The practitioner sets up the structure and possibilities in which the child's interests and ability to cope with the sensory, motor, and organization demands dictate the level of challenge and intensity of the activities. The practitioner may then use a motor learning perspective (see Chapter 55) to have the same child practicing posture and balance skills directly on a bicycle with training wheels, varying the demands of the terrain (i.e., turning corners, going up a slope) and eventually carefully removing supports such as training wheels to allow for greater balance demands, until the child was ready to ride a bicycle without supervision or physical assistance.

Scaffolding, Fading, and Coaching

Practitioners observe clients' occupational performance and adjust their grading to create the level of demand at the appropriate level to stimulate therapeutic growth or change but not so difficult as to frustrate the person, that is, to create the "just right challenge" (Ayres, 1973). Scaffolding (Rogoff, 2003; Rogoff, Goodman Turkanis, & Bartlett, 2001) is a term used when the practitioner helps the client by doing parts of the task that are too hard, but then has the client do the rest, so that a task may be completed. Much like the scaffold on a building supports the building until it is built, practitioners using this approach help clients stay motivated by seeing that they can substantially complete a task. As clients develop or improve their skills, practitioners fade or systematically withdraw supports, so that the task demands increase until the person is doing the whole task or occupation independently. For larger scale changes in constellations of occupational activities, practitioners may engage in coaching. Coaching involves providing verbal expectations and support designed to help the

TABLE 35.2   ANALYSIS FORMAT FOR ACTIVITIES AND OCCUPATIONS

	Activity Analysis	**Occupational Analysis**
Description	Describe the activity in one to two sentences.	Briefly describe the occupation. How does the person usually do this occupation and in what settings.
Objects used and their properties	Describe the tools, materials, and equipment typically used. Note the potential symbolism/meaning of the objects in the relevant culture.	Describe the tools, materials, and equipment actually used. Note the symbolism/meaning of the objects to this person.
Space demands	Describe the physical environment in which the activity is being analyzed. Include key aspects, such as the following: ◆ Does this occur in a natural or built environment? ◆ What are the major natural or built structures? ◆ Describe the placement of any furnishings and equipment. ◆ What is the light level? Does is change or is it constant? ◆ Describe the kind and level of noise. How might it impact the activity to be performed? ◆ Describe any other features which may impact the senses (ie, smell, texture, temperature) and affect performance. ◆ Is this the typical context for this activity? If not, what other contexts might be appropriate? Briefly describe them, with emphasis on how the other contexts are different.	Describe the actual physical environment in which the occupation will be performed. Consider how the physical environment supports or impedes performance. Include key aspects, such as the following: ◆ Does this occur in a natural or built environment? ◆ What are the major natural or built structures? ◆ How do structures, furnishings and equipment affect the person's performance? ◆ What is the light level and does it change? How does lighting affect performance? ◆ Describe the kind and level of noise, and how it affects performance. ◆ Describe any other features which affect the person's performance (ie, smell, texture, temperature). ◆ In addition to the context just described, where else does this person engage in this occupation? Briefly describe all additional contexts, with emphasis on how they are different from the first one described.
Social demands	Describe the social and cultural demands or the range of demands that may be required by this activity or elicited by engagement in this activity, using the categories listed below. ◆ Describe other people involved in the activity. What is their relationship to each other? What do they expect from each other? ◆ Describe the typical rules, norms, and expectations involved in doing this activity. ◆ Describe the cultural and symbolic meanings typically ascribed to this activity. ◆ Speculate about other social contexts in which the activity might be performed. How might the rules, expectations, and meanings vary from this setting?	Describe the social and cultural demands as the person engages in this occupation, using the categories listed below. ◆ Describe other people involved in the occupation. What is their relationship to each other? What do they expect from each other? ◆ Describe the rules, norms, and expectations of this person as he or she engages in this occupation. ◆ Describe the cultural and symbolic meanings that this person and his or her significant others ascribe to this occupation. ◆ Consider all the other social contexts in which the occupation might be performed. How do the rules, expectations, and meanings vary from this setting?

TABLE 35.2   ANALYSIS FORMAT FOR ACTIVITIES AND OCCUPATIONS   *Continued*

	Activity Analysis	Occupational Analysis
Sequence, timing & patterns	List the sequential steps (no more than 15) of the activity. Include any timing requirements, such as waiting for glue to dry, bread to rise, etc. ◆ How much flexibility exists in the sequence and timing of the steps of this activity? ◆ Does this activity typically occur or reoccur at a specific time of day? With what frequency? (ie, daily, weekly, monthly?)	List the sequential steps (no more than 15) of the occupation as the person does it. Include any timing requirements, such as waiting for glue to dry, bread to rise, etc. ◆ How much flexibility exists in the sequence and timing of the steps of this occupation? ◆ Does this occupation typically occur or reoccur at a specific time of day? When and with what frequency? (ie, daily, weekly, monthly?)
Required skills (observable actions)	Using the OT Practice Framework, or other published list of skills, identify 5-10 skills critical to activity performance. ◆ Consider skills which demand from the person movement, cognition, sensory and emotional perception, as well as communicative and social actions. ◆ Consider skills typically demanded from the applicable environment (physical, social and virtual).	Using the OT Practice Framework, or other published list of skills, identify 5–10 skills critical to this person's occupational performance. ◆ Consider skills which demand from the person movement, cognition, sensory and emotional perception, as well as communicative and social actions. ◆ Consider skills typically demanded from the applicable environment (physical, social and virtual).
Required body structures and functions	Consider the underlying capacities of the person which are typically required when doing this activity ◆ Briefly list the body structures (anatomical parts of the body) typically used. ◆ Briefly list the essential body functions (physiological and psychological).	Consider the underlying capacities of the person which are required when doing this occupation in the contexts just identified ◆ Briefly list the body structures (anatomical parts of the body) the person uses. ◆ Briefly list the essential body functions (physiological and psychological).
Safety hazards	List potential safety hazards for this activity. Think especially of children, people with cognitive and judgment problems, people with diminished sensation, etc.	List potential safety hazards for this person as he or she performs this occupation. Consider cognitive and judgment problems, diminished sensation, etc.
Adaptability to promote participation	How much flexibility exists for people to do this activity in different ways? Consider: ◆ Person-based variables (ie, personal context, impairments) ◆ External contextual variables (physical, social, temporal, virtual, cultural)	How much flexibility exists for this person to do this occupation in different ways? How willing is the person and key stakeholders to consider doing it differently? Consider: ◆ Person-based variables (ie, personal context, impairments) ◆ External contextual variables (physical, social, temporal, virtual, cultural)
Grading	List three ways to make the task easier in relation to an identified personal or contextual variable. List three ways to make the task more challenging in relation to an identified personal or contextual variable.	List three ways to make the occupation easier in relation to an identified personal or contextual variable. List three ways to make the occupation more challenging in relation to an identified personal or contextual variable.

*a*Adapted from AOTA (2002; 2007).

TABLE 35.3	ANALYSIS OF ORCHESTRATION OF OCCUPATIONS
Analysis of Orchestration of Occupations	
Occupations	Identify the occupations that are central to the person's identity. List these occupations.
Meaning	◆ How meaningful are these occupations to the individual? ◆ How central are the occupations to the person's identity? ◆ How important are the occupations to the individual? ◆ How important is the occupation to others in the person's social world (family, friends, co-workers, etc.)?
Purpose	What purpose(s) does each occupation play in the individual's life, e.g. self-maintenance, health, support to family, support to friends or others, contribution to community, play or leisure, work.
Level of Skill and Efficiency	For each occupation, does the individual feel that he or she is able to do this occupation at an appropriate level of skill within the expected time lines? ◆ If not what are the problems/concerns from the individual's perspective? ◆ If not, what are the problems/concerns from the perspective of people in the individual's social world?
Routines	Identify the pattern in which the individual engages in these occupations. ◆ What occupations occur daily? ◆ What occupations occur weekly? ◆ What occupations occur monthly and annually? ◆ Describe a typical day? ◆ Describe a typical week?
Organization of Routines	To what extent is the daily and weekly pattern of occupations routinized? (patterns of behavior that are observable, regular, repetitive, and provide structure for daily life. Routines, occupations with established sequences. ◆ Is the individual satisfied with this level of organization? If not, why not? ◆ To what extent do these routines meet the expectations of family, friends, co-workers ◆ Are these expectations reasonable given the person's family, physical and emotional capacities, expectations from the context, family, friends, employers? ◆ Describe the degree to which these routines are disorganized, stable, or hyperstable.
Adaptability to Promote Participation	To what extent are the occupations and/or routines flexible based on ◆ Individual-based variables: personal context, impairments, openness to change? ◆ Expectations from social environment (family, friends, co-workers) ◆ Environmental (potential to change physical environment to promote increased participation)
Needs	Describe the extent to which the occupational routine is sufficient to meet the person's needs and the needs of those in his/her social world? Describe the changes required to meet the individual's needs ◆ Changes in the individual (skill development) ◆ Changes in the social environment (expectations for performance) ◆ Changes in the occupation (adapting or grading to promote more effective performance)

individual engage in and sustain growth or changes (Clark, Ennevor, & Richardson, 1996).

Adaptation and Modification

The goal of adaptation or modification is to allow the person involvement in a valued occupation. Rather than striving to improve or change the functional capacity of the individual, adaptation focuses on changing the demands of the occupation so they are congruent with the person's ability level. These adaptations may involve the modification of the occupation itself by reducing its demands, the use of assistive devices, or changes in the physical or social environment (Dunn, McLain, Brown, & Youngstrom, 2003; Fisher, 2001, 2006). Changing the demands of the occupation may involve making it simpler cognitively or reducing the physical skills required to do it. Adaptive equipment, such as reachers or holders, may be used to enable dressing or a ramp may be used to enable access to the playground for a child who uses a wheelchair. Voice-

CASE STUDY: *Lauro, an Adolescent Who Wants to Use Public Transportation*

Lauro is a 14-year-old junior high student At a recent educational-planning meeting Lauro stated that he would like to go with his friends to a nearby sports complex on Wednesdays after school. He doesn't want his mom to drive him, but would rather go on the subway with his bud-dies. Lauro has never used public transportation and has little understanding of how to manage money. As a first step, Lauro and his OT decide to go to the subway and purchase a fare card for him to use.

Skills Selected	Behavior Observed	Performance Quality	Personal Factors Affecting Performance	Contextual Factor Affecting Performance
Three skills done well				
1. Inquires	Asked attendant where to get fare cards	Required minimal verbal cuing, and was generally socially appropriate	Appropriate awareness and thought functions needed for task, good regulation of emotions	Signage in subway entrance clearly indicates availability of attendant for help
2. Manipulates	Placed coins in the machine and is able to pick up card from machine.	Required little physical effort, was done efficiently and independently	Good sensation, joint range and muscle strength in UE	Coin slot within easy reach, as is card that comes out
3. Conforms	Waited patiently in line to ask attendant questions	Required no cuing, seemed to do automatically	Cognitively aware of implicit social rules, place of body in space, need for calm emotional response	Line was short, only had to wait about 3 minutes
Three "problem" skills				
1. Gathers	Pulled all his money out of pocket and just stood there with it in hands	Required verbal and physical cues in the form of pointing out different coins to gather needed coins	Cognitive/knowledge limitations-Not sure he knows value of coins? Can he discriminate among coins by size and design?	No wallet to organize money Few visual cues on machine as to appearance of money required
2. Chooses	As noted above, did not attempt to select coins	Needed maximum verbal assistance to select correct coins at each phase of process	Same as above	No auditory cues from machine to support performance
3. Heeds	When putting money in machine, did not change amounts he was putting in (quarters) after message told him he only needed 10 cents more	Needed verbal cues to read and interpret message, change kind of coin	Attention to visual cues, ability to match written amount (10 cents) to coin (dime).	No system for sorting change by value in his pocket Visual cues from machine placed below eye level

(Format adapted from Fisher, 2005).

Questions

1. Using the occupational analysis format, what might you do to help Lauro become better able to do the key tasks required?

2. What modifications might you make to the task or the performance setting to help Lauro perform more effectively?

3. What would you like to know about Lauro in order to make a more customized (i.e., occupational) plan?

recognition software may be used for someone who can no longer use a keyboard. Adaptation may also involve changing the social world through the provision of assistance by another person, such as a personal-care attendant or family member, to help someone with chronic mental illness to function more effectively in society (Davidson, 2003). For people with degenerative conditions, these adaptations may need to be made repeatedly as the individual's skills diminish. People with AIDS, cancer, arthritis, bipolar disorder, and other chronic illnesses may require daily adaptation because of the fluctuating levels of function typical of these conditions.

ANALYSIS OF OCCUPATIONAL PERFORMANCE SKILLS

Occupational therapy practitioners apply the analytic processes just described when observing individuals as they engage in their desired occupations. This may range from observing a student in the classroom or on the playground, a person working in an office or factory, an older adult at an assisted living facility, or a homeless person at a shelter. In all these situations the practitioner's attention is on the dynamic transaction of the person's occupational performance within the performance environment and context. Although the practitioner must be concerned with the quality of the results, the major focus is on the process of engagement. Thus, practitioners become adept at carefully observing skills associated with occupational performance. These skills represent small units of occupation, in that they are instances of the transaction among the person, occupation, and the environment in a goal-directed manner. See the Case Study for an example of how careful observations lead to intervention options using activity and occupational analysis.

CONCLUSION

This chapter describes two types of analyses: activity analysis, occupational analysis. Use of these analyses requires practitioners to understand the following:

◆ The general properties and demands of activities as they are customarily performed in given settings and cultures.
◆ How to select activities that are occupationally relevant to clients.
◆ How to select, grade, and adapt activities/occupations based on theoretical knowledge to foster development, bring about therapeutic change, or to improve performance.
◆ How to use occupations valued by clients to achieve their goals as occupational beings

These core skills are critical for effective occupational therapy evaluation and intervention. Both processes ultimately center on occupation and its capacity to motivate people to act and to create meaning in their lives. Brockelman (1980), a philosopher, recognized the importance of occupation in the following statement: "The tools of our minds and the tools of our hands are of meaningless use without deep and personal reasons of the heart to set their purpose and guide their use" (p. 24). It is through practitioners' deep understanding of people as occupational beings that effective occupational therapy intervention occurs.

Principles of Learning and Behavior Change

PERRI STERN

Learning Objectives

After reading this chapter, you will be able to:

1. Identify and describe five theories of learning: behaviorist, social cognitive, constructivist, self–efficacy, and motivational
2. Compare the essential elements and assumptions of each theory of learning
3. Explain how different theories of learning contribute to occupational therapy intervention

INTRODUCTION

◆ Julia, an inquisitive 4-year-old girl, attends the Plymouth Community Preschool. She is very talkative, friendly, and interested in most activities. However, Julia frequently takes toys from other children during free play activities. Julia's behavior causes the other children great distress, and Julia gets a lot of negative attention for her actions.

◆ Jake is a 14-year-old boy who struggles with school. For many years, he had poor school performance and was constantly told by his teachers and parents, "If you would only try harder, you'd do fine" and "We know you are smart. Why don't you work to your potential?" Over the years, Jake developed a sense of his school performance and his mental abilities as "not good enough."

◆ John, a 37-year-old man, attends a community independent living center in Boston. He has several goals, one of which is to improve his ability to organize and structure his daily self-care, productivity, and leisure occupations. A solitary person by nature, John is somewhat anxious about his ability to be successful in the program.

In addition to the situations described above, think of the many things you may have taught to different people. Perhaps you taught a younger sibling how to share toys; a friend how to navigate a bus or subway system; grandparents how to keep track of their medicines; a classmate how to organize information and prepare for an important test; a son or daughter how to overcome a fear or anxiety; yourself a new art, craft, or leisure

36

activity. How did you decide *how* to teach the person? Why did you teach the skill or behavior *in a particular way?* What *strategies* did you use? *What beliefs about how people learn guided you in your selection of strategies?* In your efforts to teach others, you have most likely developed a beginning set of beliefs about how people learn best.

This chapter presents an overview of selected *theories of learning.* In general, "learning theories" explain a perspective on what is "knowing" and how a person "comes to know" (Fosnot, 1996, p. ix). Five different overall ways of thinking about and conceptualizing theories of learning are reviewed in this chapter: behaviorist, social cognitive, constructivist, self–efficacy, and motivational. There are many other theories of learning, but these five are all relevant to occupational therapy.

> Learning theories explain a perspective on what is "knowing" and how a person "comes to know."

WHY SHOULD OCCUPATIONAL THERAPISTS STUDY THEORIES OF LEARNING?

Suinicki (2004) identified several reasons to study theories of learning. Many of these are relevant to occupational therapists. Box 36.1 summarizes six important reasons for occupational therapy practitioners to study theories of learning.

◆ Theory provides an overall *foundation for practice* in all areas of practice. People often come to occupational therapy because they want to learn new ways of doing what is important to them, and occupational therapy practitioners help people to change behaviors so that they can engage in meaningful occupations. Theory provides the basis for designing specific interventions to address client issues.

◆ Theory *guides* and *informs* practice. Theory provides us with a conceptual framework related to observations of

human behavior. Theories offer guidance about what to observe and answer questions about how best to facilitate behavior change.

◆ Theory presents an organizing framework of ideas about how people learn that leads to questions that can be tested in practice—in other words, *research.* Asking and answering questions about occupational therapy practice through research is a core responsibility for all occupational therapy practitioners.

◆ The primary goal of occupational therapy is to help people function in their daily occupations. Interventions may be designed, suggested, and implemented in many different ways. Practitioners who understand different perspectives on how people learn are likely to be more *effective* at presenting a range of interventions that match their clients' learning needs and learning styles. And when problems do arise, it is important to be able to analyze why the intervention may not be working. Understanding theories of learning will help you to *solve problems* that emerge during intervention and generate new approaches when an intervention strategy is not effective.

◆ Each client with whom you work will have different values, interests, needs, abilities, and preferred ways of learning. Understanding theories of learning will help you to design *individualized* and *creative* interventions that respond to each client's unique strengths and limitations.

◆ Occupational therapy practice should always be moving forward; it is not static. Neither is theory. Ongoing exploration of theory and theory development is a *professional responsibility* of all occupational therapy practitioners.

Theories of learning serve several other purposes. At perhaps the most basic level, they provide us with a way to organize vast amounts of knowledge that is used in practice. Theory helps us to put our knowledge together, to organize otherwise random knowledge into a cohesive set of ideas that explains some phenomenon—in this case, learning. Theories of learning enable us to see how interesting and complex even the most seemingly simple things can be. This does not mean that theory makes things more *complicated.* Rather, theory helps you to see that there is usually more to any teaching-learning situation than meets the eye. Learning theories can explain how people gather and interpret information and then determine how, if at all, information is meaningful, relevant, and memorable to their life circumstances. Theories of learning reflect beliefs about how people think and how they store and use information (Suinicki, 2004). And "since most human behavior is learned, investigating the principles of learning will help us understand why we behave as we do. An awareness of the learning process will not only allow greater understanding of normal and adaptive behavior, but will also allow greater understand-

>
> ## REASONS TO STUDY THEORIES OF LEARNING
>
> 1. Provides a foundation for practice
> 2. Guides and informs practice
> 3. Leads to researchable questions
> 4. Enhances practitioners' effectiveness and ability to solve problems
> 5. Promotes individualized and creative interventions
> 6. Core professional responsibility

ing of the circumstances that produce maladaptive and abnormal behavior" (Hergenhahn, 1976, p. 12). In any intervention situation, practitioners need to understand the reason or reasons that contribute to problematic behavior.

WHERE TO BEGIN?

What is learning? How do we know when someone is learning? Under what conditions does learning occur? Why does learning occur? What does the learner do to cause the learning? What are the outcomes of learning? The answer to all of these questions is "it depends." It depends because different learning theories attribute different causes, reasons, actions, and circumstances to learning.

BEHAVIORIST THEORY

Behaviorist theory focuses on how observable, tangible behaviors are learned in response to some environmental stimulation (Ormrod, 1990). Behaviorist theorists focus on observable events rather than mental processes. For example, how does a child learn to take turns while playing a game with friends, how might a person with a developmental disability learn to respond appropriately in a conversation, and how would a person learn to propel and navigate a wheelchair in an urban community? In these examples, the observable events are the child waiting for and taking his or her turn during a game of kickball, a person waiting for a conversation partner to finish speaking before providing new information, and a person successfully navigating the urban community in a wheelchair. The overall emphasis in behavioral theories of learning is on the relationship between an environmental stimulus and a behavioral response and on how learning is indicated by an observed change in behavior.

What Are the Essential Elements and Assumptions of Behaviorist Learning Theory?

Behaviorists use the term *conditioning* to explain changes in behavior rather than learning, as behaviorist theory assert that a person's behavior is conditioned by events in the environment. A behavior is gradually shaped, changed, and molded as it reflects the environment's response to the behavior. There are several key terms that you will notice in most types of behavioral theory: **conditioning** (designing situations that increase or decrease the likelihood of a behavior being performed), **stimulus** (something that prompts a behavior), **response** (the reaction to the stimulus), **shaping** (a strategy to develop closer and closer approximations of a behavior), **punishment** (response to an undesired behavior), and **reinforce-** **ment** (something that causes a behavior to be strengthened and performed again).

Many well-known theorists have contributed to the development of the behavioral perspective, such as Ivan Pavlov (1849–1936), Edward Thorndike (1874–1949), John Watson (1878–1958), and Burrhus Frederic (B. F.) Skinner (1904–1990). Although their theories are slightly different from each other, they do share common assumptions about the nature of learning, chiefly the need to focus on external, observable events as evidence of learning (Ormrod, 1990).

Ivan Pavlov developed the theory of *classical conditioning,* which resulted from his initial studies of a dog's salivation response to a *neutral stimulus,* then to a neutral stimulus plus an *unconditioned stimulus,* and finally to a *conditioned stimulus.* As a result of his experiments and observations, Pavlov concluded that changes in behavior (learning) are due to *experience.*

Thorndike's perspective is known as *connectionism,* whereby learning is seen as a process of making connections between things, understanding the relationship of a stimulus to a response. Thorndike studied how people established those connections and therefore how people developed and maintained behaviors. He emphasized the role of practice and experience in strengthening or weakening the connections between a stimulus and a response. Through a series of experiments, Thorndike concluded that the learning of a behavior is elicited by the consequences of the behavior. So responses to a behavior that were followed by a satisfying experience would be rewarded, thus strengthening the connection, the neural bond between the stimulus and the response, and increasing the likelihood that the behavior would be produced again. He originally thought that responses that were followed by discomfort or dissatisfying experiences would be weakened and eventually stop; but he revised that and deemphasized the role of punishment. Instead, Thorndike believed that punishment would have an indirect effect on learning—that as a result of some dissatisfying response from the environment, an organism would engage in some other behavior.

Watson introduced the term *behaviorism.* He emphasized the importance of focusing on observable behaviors. Watson was greatly influenced by the work of Pavlov. As he expanded on Pavlov's work, Watson proposed two "laws" that explained the relationship between stimulus and response and ultimately how behavior is learned. Watson proposed that "the more frequently a stimulus and response occur in association with each other, the stronger that Stimulus-Response habit will become" (Ormrod, 1990, p. 20). This was termed the *Law of Frequency.* Watson also proposed that "the response that has most recently occurred after a particular stimulus is the response most likely to be associated with that stimulus" (Ormrod, 1990, p. 20). This was termed the *Law of Recency.*

B. F. Skinner was influenced by both Pavlov and Watson. He coined the term **operant conditioning**. Skinner's basic principle was that a response followed by some reinforcement is likely to be strengthened. And since a response is a change in behavior, then from a behaviorist perspective, this indicates learning. Any behavior, positive or negative, can be reinforced.

Skinner used the term *reinforcement* rather than *reward* for two reasons. First, he believed that the term *reward* implies something pleasant or desirable, but sometimes people intentionally do things to produce an unpleasant consequence (e.g., a person might do something to make another person angry because the first person enjoys watching the second person get angry). Second, the terms *reward, pleasant,* and *desirable* are highly subjective terms. Behaviorists such as Skinner preferred to keep things objective and scientific.

There are three important conditions for operant conditioning. First, the reinforcement must follow, not precede the response. Second, the reinforcement should immediately follow the behavior. Otherwise, the reinforcement will have less effect. Third, the reinforcement must be contingent on the response; it should not be given for an unintended or unrelated response.

How is operant conditioning different from classical conditioning? In classical conditioning, there is an unconditioned stimulus and a conditioned stimulus. The conditioned stimulus brings about the conditioned response. The response is automatic and involuntary. In operant conditioning, a response is *followed by* a reinforcing stimulus. The response is *voluntary.* The organism has control over whether it emits the response. For example, operant conditioning would be illustrated when John, the 37-year-old man attending a community independent living center, receives praise and enthusiasm when he attends the center. As a result, John attends the center much more regularly.

Occupational Therapy and Behaviorist Theory

Occupational therapy practitioners using behaviorist theory to understand human learning and guide their intervention would analyze a complex behavior that needs to be learned (e.g., Julia's need to take turns when she plays) and sequence that behavior from simple to complex. Intervention would consist of opportunities for the person to participate in increasingly complex behaviors, using behaviorist principles such as reinforcement, shaping, and reward. Progress would be measured by clients' observed occupational performance and their ability to complete increasingly complex behaviors necessary for occupational performance.

Occupational therapy practitioners have used the behavioral theory of learning in several ways to guide their interventions with clients. For example, Giles and Wilson (1988) and Giles, Ridley, Dill, and Frye (1997) described programs to help retrain people who had sustained severe brain injuries. The clients had severe physical and cognitive impairments and needed help with washing and dressing, basic self-care behaviors. The practitioners designed and implemented a program that consisted of individualized plans to break down each larger activity (getting dressed) into its smaller elements. Practitioners used a specific set of instructions to gradually add skills to each person's repertoire and eventually teach the entire behavior.

Katzmann and Mix (1994) presented a case report of a 34-year-old woman with viral encephalitis. The woman had difficulty processing written and verbal information and had great difficulty with various complex self-care tasks. The practitioners' intervention was influenced by behavioral theories, using such techniques as prompting with step-by-step instructions, shaping, and verbal or physical cues. The practitioners identified and sequenced all of the steps required for the woman to complete her washing, dressing, and grooming routine, which began with getting out of bed and ended with going to breakfast in the rehabilitation facility. A series of step-by-step instructions, gradual and consistent shaping of behavior, verbal cues, and physical assistance helped the woman to improve her overall ADL functioning. The practitioners cued the woman with directions or provided physical assistance for a step that needed to be completed and gradually removed the cues as she initiated and completed the task independently.

Behaviorist theories emphasize observable behavior, rewarding and reinforcing desirable behavior and reducing problematic behaviors. Clients who might benefit from intervention approaches that are grounded in behaviorist theories of learning include people who have difficulty planning and organizing activities, those who have problems with memory and/or attention, those who have deficits in sequencing activities, and those who demonstrate inappropriate social behaviors. Some strategies that could help Julia to develop sharing and turn-taking skill include praising appropriate behavior (to provide reinforcement for sharing), not giving attention every time she takes toys from others (to decrease the reinforcement for the undesired behavior), using a sticker chart to document sharing (to gradually shape appropriate behavior), and providing rewards to Julia for good sharing, such as letting her stand first in line to go to the playground.

SOCIAL LEARNING AND SOCIAL COGNITIVE THEORY

The social learning and social cognitive theory of learning are an outgrowth of behaviorist theories. Theorists such as Piaget (1970) and Bandura (1977a) were dissatisfied with the limits of behaviorist theory, because they believed that there was more to learning than just the interaction of a

person with the environment. They developed theories of learning that integrated behavioral, social, and cognitive processes. Although there are individual variations and areas of focus, in general social cognitive theory explains learning as occurring in a social context, that is, the "where, what, when, with whom, how often, and under what circumstances" aspects of our lives. Humans learn by observing others, cognitively processing observations, storing those observations and thoughts, and then using them, sometimes at a much later time. This is an important contrast with behaviorists, who view learning as an observable change in behavior. Social learning/social cognitive theorists disagree and say that *learning can occur even in the absence of an observable change in behavior.* Social and cognitive processes such as observation, storing observations in memory, self–assessment, and appraisal promote learning. The interactions between a person, behavior, and the environment are emphasized.

Five major assumptions are inherent to social learning/ social cognitive theory (Ormrod, 2006). First, *people can learn by observing others.* Second, *learning is an internal process.* Learning itself might or might not lead to an observable change in behavior. For example, people might observe various social skills, such as how to introduce themselves to someone they meet, how to end a conversation politely, and how to maintain an appropriate social distance during a conversation. These skills might be stored in memory for future use and not be immediately demonstrated. Third, people are generally *motivated to achieve goals* for themselves, and their behavior is typically directed toward those goals. Fourth, social cognitive theories assert that instead of learning being a direct response to and dependent on environmental stimuli, learning occurs as *people regulate and adjust their own behavior.* This means that people would observe others, determine their own individual standard, and then work to behave according to those standards. Fifth, feedback via reinforcement and punishment affect learning and behavior *indirectly* (not directly, as the behaviorists believe). This means that people can adjust their behavior on the basis of the *anticipated* (positive or negative) consequences. Or people might observe the outcomes of a behavior that is demonstrated by others and adjust their behaviors on the basis of that observation. (Ormrod, 2006). Box 36.2 summarizes these major assumptions.

It is important for a person to observe skills and behaviors via models and to note the reinforcement that models receive for behaviors. Models can be *live,* that is, a person with whom the learner has actual contact, or *symbolic,* some pictorial or abstract representation of behavior, such as through television or other media. Whatever the source, the modeled behavior serves as information to the observer/ learner. A person can also learn *vicariously,* increasing or decreasing a given behavior on the basis of the reinforcement that the person observes someone else receiving. If a behavior is positively reinforced, the observer might increase that behavior. If the behavior is negatively rein-

---

BOX 36.2

MAJOR ASSUMPTIONS OF SOCIAL COGNITIVE THEORY OF LEARNING

- People can learn by observing others.
- Learning is an internal process.
- People are motivated to achieve goals.
- People regulate and adjust their own behavior.
- Reinforcement and punishment may have an indirect effect on behavior.

---

forced, the observer might decrease that behavior. Other determining factors include how much attention gets paid to the model, how credible or prestigious the model is, and how the model is rewarded (Ormrod, 2006).

Because people can learn by observing others, *attention* is a very important factor. A learner is more likely to remember information when the learner consciously attends to the behavior, rehearses it in his or her own mind, and develops personal verbal or visual ways to represent the information for future use (Ormrod, 1990). A person should be able to describe the behavior or have a picture of that behavior in his or her mind, stored for future use.

People develop expectations about what they think will happen as a result of different behaviors. Thus, *incentive* is an important consideration. Incentive is the anticipation that something will happen (reinforcement) if a particular behavior is performed or not performed. This is another difference from behaviorist theory. According to operant conditioning theory, the reinforcement comes after the behavior has been performed. In social cognitive theory, an anticipated outcome might precede the behavior being performed (or not performed).

An occupational therapy practitioner working with Jake, the 14-year-old who is having difficulty at school, might have Jake *identify* specific problem situations (e.g., being distracted in class, using minimal effort to complete projects, or becoming bored in class) and then identify specific strategies to address these difficulties (e.g., sitting at the front of the classroom, setting "effort goals" for himself, identifying at least one interesting aspect of any project), *set* manageable and measurable goals, and then *develop* a mechanism to determine how well he had achieved his goals. The occupational therapy practitioner might also encourage Jake's teacher to pair him with classmates who demonstrate good study habits and who are highly motivated for learning. Or the practitioner might role-play conversations that Jake is likely to have with his parents or teachers about his feelings and attitudes toward schoolwork. The role-play conversations could help Jake to articulate his concerns and then work to support his learning.

A variety of occupational therapy intervention programs have incorporated aspects of social learning theories.

Jao and Lu (1999) studied the effects of a problem-solving intervention on the interpersonal skills of people with chronic schizophrenia. They found that helping people with schizophrenia to recognize and define problems, think of alternative solutions, and determine the best course of action facilitated the development of interpersonal problem-solving skills.

Stern (1991) described a psychoeducation treatment program on a research unit for people with schizophrenia. Here, clients participated in a series of weekly intervention groups that were based on the assumption that behavior that departs from social norms is the result of a person's unsuccessful attempts to cope with environmental demands and that skill deficits are primarily a result of insufficient or unavailable opportunities for social learning. Clients attended groups to help them develop skills for managing time, stress, money, and their own personal care.

Most of these programs emphasize the importance of learning in a social context, providing numerous opportunities for clients to develop or relearn essential skills for living, and employ activities such as role-play, observation, problem solving, and practice in real-life situations.

CONSTRUCTIVIST THEORY

Suppose you are an occupational therapy practitioner working in a community independent living center. Your clients are typically recovering from substance abuse or might have chronic mental illness. Part of your intervention includes a series of Life Skills sessions that are designed to help people learn or relearn different instrumental activities of daily living. A new session will begin next week with five new clients. One segment of your program focuses on time use and leisure planning. Will all of the five clients come to the course with the same life experiences? Will all of the five people have the same outlook on life? How might you understand the teaching-learning process, given these individual differences and experiences?

A constructivist would assert that individual differences are to be expected, that "everyone's construction of the world is unique even though we share a great many concepts" (Suinicki, 2004, p. 14). Although there are several "traditional" methods of providing information, such as through imparting information or finding information in books or on the Internet, this does not necessarily indicate or result in learning, according to constructivism. For constructivists, the learner must *access* information, use this information to *alter* or modify existing knowledge and understanding, and *integrate* the new information with previous information to *create* a new understanding that is relevant to himself or herself (Marlowe & Page, 1998). For the Life Skills challenge posed above, a constructivist would embrace the members' different perspectives and perceive them as essential to individual learning.

There are some basic assumptions about the teaching-learning process that are common to constructivism: First, learners must be *active participants* in their learning. Second, the learner is capable of *creating* his or her own *knowledge* through interaction with the human and non-human environment. Third, when learners participate in this type of learning environment, they develop the *ability to think critically* to solve problems. Fourth, when actively engaged in constructing their own knowledge, people *gather information and develop strategies* at the same time (Marlowe & Page, 1998).

Bruner (1961) has had a major influence in the development of constructivism or "discovery" learning. According to Bruner (1961), a constructivist approach fosters *intellectual potency,* meaning that when people seek and find information for themselves, that information is more meaningful, relevant, and powerful for them. Furthermore, people organize information they find for themselves so that it is more efficiently and effectively retrieved for future use. Second, since the learners "own" the information, this approach fosters *intrinsic motivation.* Rather than settling into a pattern in which learners conform to what the instructor wants them to learn, learners *discover* for themselves. This promotes motivation to learn. Third, the only way to improve one's ability to think, question, and discover is to do it, actively and repeatedly; to engage in the process. Constructivism fosters people's learning the *process of discovery.* Finally, when people learn and discover for themselves, they also organize, categorize, and store that information in ways that are personally meaningful. Such information is more easily accessed when needed. Constructivists call this a *conservation of memory.* Box 36.3 summarizes the major assumptions of constructivism.

A practitioner who utilizes a constructivist approach in the teaching-learning process emphasizes skills and activities such as asking questions, independent exploration, identifying problems, brainstorming, and generating individual solutions to problems. The practitioner emphasizes the *client's essential role in the process* and sees his or her own role as facilitating clients' progress. The practitioner views the therapy process as recognizing, embracing, respecting, and encouraging people to develop individual meanings, to promote and enhance the client's knowledge and skill.

In this perspective, clients are expected to actively direct what needs to be learned and how the learning will occur. Clients help to determine the resources that will enhance their learning. Independent thinking, collaborative problem solving, and using past experience to reframe and revise new learning are all important. The practitioner's knowledge and expertise are still very important; however, in this perspective, the practitioner uses his or her knowledge and expertise as a point of reference. In many ways, the practitioner takes a "back seat" as the client pursues learning; the practitioner's role is to address problems that arise. The practitioner facilitates the process, using himself or herself to promote the client's ability to identify, address, and solve problems.

MAJOR ASSUMPTIONS OF CONSTRUCTIVIST THEORY OF LEARNING

◆ Learners must be active participants in their learning.
◆ Learners are capable of discovering and creating their own knowledge.
◆ Active participation in the learning environment enhances critical thinking and problem-solving abilities.
◆ Active participation in the learning environment enhances the meaning and relevance of the learning experience and motivation for learning.
◆ In learning, people gather information and develop problem-solving strategies simultaneously.

Constructivism "allows for multiple perspectives to emerge and new solutions to arise synergistically. The role of teacher shifts from one of directing and controlling learning to that of facilitating change" (Lederer, 2000, p. 84). Rather than being viewed as the expert and the person who will recommend a particular intervention or plan of action, the practitioner facilitates discovery and meaning, discussion, and problem solving. The occupational therapy practitioner does not provide "the intervention" but instead works to facilitate the person's developing his or her own strategies to deal with his or her own issues. The practitioner is alert to major issues but is neither prescriptive nor directive.

PRACTICE DILEMMA

CONSTRUCTIVIST PERSPECTIVE ON LEARNING

If each person constructs his or her own learning and therefore there is no "objective reality," what challenges does that present to an occupational therapy practitioner who advocates a constructivist perspective on learning? What opportunities does it provide to the practitioner and/or to the person with whom the practitioner is working? What are some strategies that you could implement to address clients' time use and leisure skill development in the Life Skills program described earlier?

SELF-EFFICACY THEORY

The self-efficacy theory of learning focuses on a person's individual beliefs about how effective he or she is or will be at learning or completing a new skill or behavior. Albert Bandura (1977b) first articulated a theory of self-efficacy. His perspective on how behaviors are learned and changed involved behavioral *and* cognitive processes. His central thesis is that a person's **efficacy expectations**, the person's beliefs about how successful or unsuccessful he or she will be at performing a skill or occupation, will greatly influence their execution of that skill or occupation. The emphasis here is on the *person's beliefs* and *how those beliefs influence their performance.* For example, a person might believe that a particular action performed or executed by a person *in general* will produce a certain outcome. However this is different from the person's belief that he or she has the ability to perform the action and that it will result in a successful outcome. A person's efficacy expectations also influence the person's *persistence* with different occupations. "Efficacy expectations determine how much effort people will expend and how long they will persist in the face of obstacles and aversive experiences. The stronger the perceived self efficacy, the more active the efforts" (Bandura, 1997b, p. 194).

Efficacy expectations have three important dimensions: magnitude, generality, and strength (Bandura, 1977b). *Magnitude* involves the level of difficulty for a task—for example, making a sandwich versus making an elaborate dinner or writing an outline versus writing a lengthy research paper. *Generality* involves the degree to which a person's perceived self-efficacy for one task transfers to another—for example, maneuvering a wheelchair around the occupational therapy clinic versus maneuvering a wheelchair in a busy urban community or making a sandwich at the occupational therapy clinic versus making a sandwich at home. *Strength* refers to the degree to which people believe they can be successful—for example, being very, very confident and having strong beliefs about one's success versus being only slightly confident or uncertain about the likelihood of success.

Typically, a person's self-efficacy is developed over time and through four sources of information: outcomes that were generated by the person's own *personal accomplishments;* through *vicarious experience,* that is, seeing others perform a skill and through that vicarious experience believing that "if the other person can accomplish the skill so can I"; by being *persuaded* by others that the person can be successful; and by *feeling calm and relaxed* when performing a skill (Bandura, 1997b). Which of those four elements has the strongest effect? Personal accomplishment. Although a person might perform a task successfully as observed by an outsider or through feedback from the environment, the person's *own cognitive appraisal* of how successful or unsuccessful he or she was will greatly affect the person's efficacy expectation. Vicarious experience, persuasion, and a calm feeling are

all helpful, but none are as strong as a person's actual success in performing a skill (Bandura, 1997b).

The power of a person's beliefs about his or her skills and abilities is an important point. As Gage and Polatajko (1994) noted,

> Therapists often try to convince clients that they are able to go home and live independently, or return to work, only to be confronted with a barrage of reasons why the client is not yet ready. These patients are labeled as fearful or, worse yet, as malingerers. Perhaps it is simply their perceived self efficacy for home management or work activities that has not yet reached the level necessary to engage the activity independently. If one accepts that persuasion is the least influential method of raising efficacy expectations, then the therapist must devise new intervention techniques. (p. 460)

Although the two concepts are related, perceived self-efficacy is not the same as self-esteem. Perceived self-efficacy is what you believe you can do with your skill. Self-esteem refers to a person's negative or positive sense of self. So a person might feel that he or she is competent and successful in completing a variety of occupations but might have an overall negative feeling about himself or herself. Certainly, perceived self-efficacy might contribute to a person's self-esteem, but they are two separate concepts (Gage and Polatajko, 1994).

According to Bandura (1997a), self-efficacy relates to behavior change very directly. If a person has only weak expectations for his or her success, it is likely that unsuccessful experiences will quickly result in the person's not performing the skill or behavior. If the person's beliefs about his or her success are strong, then it is likely that the person will persist, even through negative or unsuccessful experiences.

PRACTICE DILEMMA

PROMOTING SELF-EFFICACY

Core principles of occupational therapy, such as using strengths to overcome limitations, and person-centered intervention, are very consistent with developing and promoting self-efficacy. And according to Gage & Polatajko (1994), "the most effective means of enhancing perceived self-efficacy is deemed to be through performance based procedures" (p. 452). At the beginning of this chapter, you read about Jake and his difficulties at school. How might you understand his situation from the perspective of self-efficacy theories? What are some strategies that might be helpful to Jake?

MOTIVATIONAL THEORY

Prochaska, Norcross, and DiClemente (1992) propose a *transtheoretical stage theory* of how people learn to change behaviors. The term *transtheoretical* refers to the integration of several different theories from the disciplines of psychology and psychotherapy. Prochaska and his colleagues have applied their transtheoretical theory of change to a variety of health behaviors and systems issues, such as smoking cessation (Prochaska & DiClemente, 1983), addressing health risk behaviors (Nigg et al., 1999), arthritis self-management (Keefe et al., 2000), organizational change (Prochaska, Prochaska, & Levesque, 2001), and weight control (Sarkin, Johnson, Prochaska, & Prochaska, 2001). This model has two essential elements: the five integrated *stages* of change and the various *processes* that can facilitate a person's moving from one stage to the next.

The stages of change begin with *precontemplation.* Here, a person might have a behavior that is perceived by others to be harmful or destructive (e.g., a substance use or addiction, poorly controlled anger or stress, or general health and wellness issues). The person might be unaware or minimally aware of his or her problem, or the person might be aware of the problem but resistant to fully acknowledging or addressing it. A person who has progressed to the second stage, *contemplation,* is likely to be aware of his or her problem and is thinking about overcoming it but is not quite ready to take action. When a person begins to make some small changes in his or her behavior, the person has progressed to the third stage, *preparation.* The fourth stage is *action.* This is when the most substantive change occurs. The person is putting forth great energy to modify behaviors, the environment, or his or her experiences to effect serious change. The fifth stage is *maintenance.* Here, the person works to sustain accomplishments and prevent relapse (Prochaska, Norcross, & DiClemente, 1992).

These stages might appear to be linear, occurring in a step-by-step progression from one stage to the next. However, Prochaska, Norcross, and DiClemente (1992) explain change as occurring in a spiral fashion, because most people experience relapses or other setbacks as they work to change behaviors. Have you or a friend set out to change a certain behavior and achieved stage three (preparation) or stage four (action) only to experience some setback and spiral back down to an earlier stage? According to Prochaska's theory, this is common and to be expected.

The *processes* of change, the second part of Prochaska's theory, explain *how* to promote the shifts. According to Prochaska, Norcross, and DiClemente, (1992), people who have reached the contemplation stage are ready to understand the processes that can contribute to behavioral change. Their research indicates that people who are in the precontemplation stage lack the awareness to engage in or benefit from the processes of change. People who have progressed to the contemplation stage may benefit

from *consciousness-raising* strategies that help them to get information about their problem and themselves, by being encouraged to express their feelings about their problems through various *dramatic relief* strategies such as role-playing, and by *environmental reevaluation* to assess how their behavior affects their physical and social surroundings (e.g., perhaps a person's smoking deters family or friends from visiting or there are stains and cigarette burns on the person's furnishings). Strategies such as values clarification exercises to enhance *self-reevaluation,* or how one thinks and feels about himself or herself, can be helpful as one moves to the preparation stage. Making a real commitment to change, believing in one's ability to change, and using techniques such as personal goal setting to enhance *self-liberation* or will power can be helpful during the action stage. Several processes are important in the maintenance stage, such as fostering *helping relationships* and social supports that encourage the person to be open and honest about his or her problems, avoiding things that elicit the problem behavior and substituting alternatives (*stimulus control* and *counterconditioning*), and *reinforcement management,* rewarding oneself for making changes. *Social liberation* helps to promote change across various stages through advocacy, empowerment, and social change mechanisms (Prochaska, Norcross, & DiClemente, 1992).

The key to success for this model is the careful, systematic, and close fit between the person, the stage, and the process. According to Prochaska, Norcross, and DiClemente, (1992), "efficient self-change depends on doing the right things (processes) at the right time (stages)" (p. 1110). Table 36.1 summarizes Prochaska, Norcross, & DiClemente's (1992) stages and processes of change.

OCCUPATIONAL THERAPY, SELF–EFFICACY THEORY, AND MOTIVATIONAL THEORY

Both self-efficacy theories and motivational theories have great relevance for occupational therapy. Often, a person's self-perceptions and beliefs about his or her ability to be successful with an occupation influence the person's decision about whether to participate in that occupation. For example, a person who believes that he or she has good interview skills will be more likely to respond to a job advertisement even though he or she might not have direct experience with the type of work that needs to be done. A person who did not have that sense of effectiveness might be less likely to pursue the job. Intervention strategies to promote a person's perceived self-efficacy in the job interview situation described here would include determining with the person that he or she had all the requisite skills to be successful, using peer role models so that the person could practice or "try on" the essential skills and behaviors, having the person practice interview skills, providing feedback on specific successes, and encouraging the person to evaluate his or her skills in a personal way rather than comparing these skills to someone else's. These theories all emphasize the importance of an individual's participation in *meaningful* occupations as both the foundation and result of motivation and self-efficacy.

Gage, Noh, Polatajko, and Kaspar (1994) developed an assessment that could be helpful to occupational therapists. Their assessment, the Perceived Self Efficacy Gauge, evaluates perceived self-efficacy of adults who have physical disabilities and identifies changes in a person's perceived self-efficacy over time. It promotes the belief that "clients with greater confidence in their ability to regain their usual level of competence for daily activities are less likely to develop hopeless feelings" (Gage, Noh, Polatajko, & Kaspar 1994, p. 785).

Ehrenberg, Cox, and Koopman (1991) studied the relationship between perceived self-efficacy and depression in adolescents. "Perception of self-efficacy can be critical to adolescent development, especially in regard to academic performance, social competence, career choice and physical confidence" (p. 363). Ehrenberg, Cox, and Koopman (1991) learned that adolescents with higher levels of perceived self-efficacy had less depression than did adolescents who had lower levels of perceived self-efficacy.

TABLE 36.1	STAGES AND PROCESSES OF CHANGE
Stage	**Process (How to Promote Change)**
Precontemplation	Strategies are not effective, as the person lacks awareness to engage in or benefit from change
Contemplation	Consciousness-raising strategies to learn about problem, role-play strategies to express feelings, assessment of how behavior affects physical and social environment
Preparation	Values clarification exercises to promote reevaluation of feelings or self-perception
Action	Goal-setting strategies and techniques
Maintenance	Development of social supports, substitution of alternatives to problem behavior, avoidance of experiences that elicit the problem behavior, rewarding oneself for making changes

CASE STUDY: *Olivia: Behavior Change*

Olivia, a 55-year-old woman has always been severely overweight. Over the years, she has tried many different diets and has joined (and quit) numerous exercise programs and groups. After a recent episode of chest pain, Olivia's health care provider strongly recommended that she participate in organized nutrition, exercise, and overall health-promotion activities.

> How might you help Olivia to understand and reflect on her challenges with health and wellness issues over the years through the transtheoretical perspective?
> What stage might she be at currently?
> How might you help her move from one stage to the next?
> How might you work to minimize any setbacks to the process and remedy those setbacks when they occur?

Strategies might include the following:

> The occupational therapy practitioner would work with Olivia to help her understand the processes of change. Their work together would include helping Olivia to understand how change occurs, the spiraling nature of

change, and the natural, to-be-expected gains and setbacks that occur.

The occupational therapy practitioner would use counseling and discussion to encourage Olivia's conscious reflection on her behavior and recognition of the different stages of change. Olivia's current stage could be seen as preparation.

A variety of intervention strategies, such as personal goal setting, developing social supports, creating a self-reward system for positive change or progress, and evaluation and reevaluation of progress, could be suggested.

Olivia would also be encouraged to view earlier obstacles or setbacks to change as typical and predictable. When setbacks do occur, the occupational therapy practitioner would reinforce the importance of conscious understanding of the spiraling nature of progress, the success of identifying setbacks when they occur, the opportunity to prevent any setback from spiraling too far down, and a return to strategies that were successful in the past or continuing to develop new strategies. The occupational therapy practitioner would reinforce the ongoing nature of change and progress.

CONCLUSION

Behaviorist, social cognitive, constructivist, self-efficacy, and motivational theories of learning have great relevance and utility for occupational therapy practitioners. Table 36.2 summarizes the five different theories of learning that were presented in this chapter and highlights their relevance to occupational therapy practice. The information presented in this chapter can be used to influence how you think about the learning needs of patients and clients, to reinforce the importance of designing optimal learning environments, to contribute to your ongoing professional development, and to promote your clients' abilities to achieve their goals.

TABLE 36.2   SUMMARY TABLE

Theory	Major Emphases	Relevance to Occupational Therapy Practice
Behaviorist	◆ Learned behavior as an observable event (not a mental process) ◆ Behavior is conditioned by the environment ◆ Environmental response alters subsequent behaviors	◆ Analyze and sequence behaviors from simple to complex ◆ Measure progress as the person completes increasingly complex behaviors ◆ Use strategies including reinforcement, shaping, and rewards

TABLE 36.2   SUMMARY TABLE   *Continued*

Theory	Major Emphases	Relevance to Occupational Therapy Practice
Social learning/social cognitive	◆ Integrates behavior, social, and cognitive processes ◆ Learning occurs in a social context ◆ Learning may occur without observable behavior change ◆ Person regulates and adjusts his or her own behavior	◆ Emphasize client learning essential skills for living ◆ Use role-play, peer observation, role modeling, problem solving, and real-life practice activities to promote learning ◆ Encourage the client to identify the problem, set goals, develop a plan, evaluate outcomes
Constructivist	◆ Learner is an active participant in his or her own learning ◆ Learner creates/constructs knowledge through past experience and interaction with the environment ◆ Self-constructed knowledge has great meaning and relevance for the learner ◆ Self-constructed knowledge promotes the learner's motivation for learning	◆ Client actively directs what is to be learned and how learning will occur ◆ Use strategies including brainstorming, individual problem-solving, independent exploration, asking questions. ◆ Occupational therapist facilitates but does not direct the learning process
Self-efficacy	◆ Emphasize a person's beliefs about how effective he or she is or will be ◆ Efficacy expectations influence a person's persistence with an activity ◆ Efficacy expectations are influenced by the difficulty of the task, how well completing a task transfers to other situations, and the degree to which a person believes that he or she will be successful ◆ Self-efficacy is developed over time and through experience	◆ Personal accomplishment has the greatest effect ◆ Self-evaluation, personal appraisal are important ◆ Tasks should be challenging but not overwhelming, should be transferable to other situations ◆ Vicarious, observation experiences and/or persuasion to enhance the person's beliefs that he or she can be successful are less effective
Motivational	◆ Learning and change occurs in a spiral fashion. It is not linear. ◆ A person's readiness for change will influence the outcomes ◆ Relapses are common and to be expected	◆ Intervention processes must match behavior stage ◆ Intervention processes become increasingly active, self-directed and self-monitored

Group Process

SHARAN L. SCHWARTZBERG

Learning Objectives

After reading this chapter, you will be able to:

1. Appreciate the complexity and value of small groups in occupational therapy.
2. Understand factors influencing small group development and leadership.
3. Analyze the influence of intrapersonal, interpersonal, and intersubjective aspects of group process and dynamics.
4. Identify the impact of task, leader, and member responses on group processes and the effect of group dynamics and processes on individuals, subgroups, and the group as a whole.

INTRODUCTION

Occupational therapists work in groups in a variety of settings. These settings include natural groups such as staff meetings and intervention groups for the purpose of therapy. Occupational therapy groups include energy conservation groups, psychoeducation groups, social skills groups, activities of daily living groups, reminiscence groups, and sensory stimulation groups, among others. The age range of members of these groups is very broad, from children to older adults, and settings include all areas of practice. There are sets of dynamics that operate in small groups regardless of setting. The interrelationships between members, leaders, and the group as a whole are called **group process**. The purpose of this chapter is to define group process and the dynamics that influence **group cohesiveness** and the dissolution of a small group. Factors such as cohesiveness, hope, and interpersonal learning are what make therapeutic groups beneficial (Falk-Kessler, Momich, & Perel, 1991; Yalom, 1985; Yalom & Leszcz, 2005).

DEFINING GROUP PROCESS

Group process "is the **here-and-now** experience in the group that describes how the group is functioning, the quality of relationships between and among group members and with the leader, the emotional experiences and reactions of the group, and the group's strongest desires and fears" (Brown, 2003, p. 228). According to Brown, "the proposed definition has the following components and assumptions: (1) process occurs in the here-and-now; (2) process includes present relationships and interactions among group members and with the leader; (3) reactions, responses, and feelings provide access to and meaning for process; and (4) process exists at both the micro and macro levels" (2003, p. 228). Each of these components will be explained in terms of processes relevant to occupational therapy (Figure 37.1).

FIGURE 37.1 Occupational therapy often occurs within a group format. (Photo courtesy of Kinda Clinetf.)

Here-and-Now Process

The moment-to-moment interaction between leaders and members makes up the here-and-now process of a group. At a minimum, as an interdependent system, interaction operates simultaneously in six ways: (1) member to member, (2) leader to member and member to leader, (3) subgroups, (4) group as a whole, (5) engagement in occupation, and (6) the culture or environment. In a **functional group** (Howe & Schwartzberg, 2001; Schwartzberg, Howe, & Barnes, 2008), purposeful action promotes adaptation through engagement in occupation. The actions that are characteristic of a functional group, described by Howe and Schwartzberg (2001), include four types of group action: (1) purposeful action, (2) self-initiated action, (3) spontaneous action or here-and-now action, and (4) group-centered action. A snapshot example of group-centered action is a group of people making a decision together to do something of value to the group. The members act spontaneously in offering suggestions and supporting each other emotionally. There is a balance between getting the decision made and feeling satisfied (Box 37.1).

Relationships and Interactions Among Members and with the Leader

Factors that influence the group process include the role of the group leader, the group format, and the functional level of the members. Leadership can be highly structured and autocratic (leader-centered), centered on the needs of the group, or open-ended. Groups can be closed, with no new members added, or open with changing membership. Members can be selected to be like one another or heterogeneous. Small groups can range in size from three members to ten or even twelve members. Group size influences group methods, leader strategies, and outcomes (Howe & Schwartzberg, 2001).

Group membership roles have been categorized into three types of roles that are social-emotional positive or negative and task area neutral (Bales, 1950): (1) group maintenance and building roles, such as "encourager," "harmonizer," and "compromiser;" (2) group task roles, such as "initiator-contributor," "information seeker," and "information giver"; and (3) individual member roles, such as, "aggressor," "blocker," and "recognition seeker"

BOX 37.1

HOWE AND SCHWARTZBERG'S (2001) FUNCTIONAL GROUP ACTIONS

- ◆ **Purposeful action:** Meaning for individuals and group as a whole
- ◆ **Self-initiated action:** Member takes initiative verbally or nonverbally
- ◆ **Spontaneous action:** Action occurs in the here and now
- ◆ **Group-centered action:** Member actions are interdependent

BOX
37.2

GROUP MEMBERSHIP ROLES (BENNE & SHEATS, 1978)

◆ **Group maintenance-building roles:** Social-emotional roles that support group processes
◆ **Group task roles:** Member roles that support group task goals
◆ **Individual member roles:** Individual roles that detract from group processes

(Box 37.2) (Benne & Sheats, 1978). People take on these various roles in task-oriented groups. There may be a mismatch between the roles members take on and the demands of a situation. If everyone offers emotional support and no one carries out actions such as offering suggestions, the group falters. Conversely, if the group focuses only on getting the job done, the members will feel emotionally dissatisfied and isolated. Group cohesion results when the member roles are congruent with the task.

The developmental level of the group can be viewed in relation to the member function, complexity of task, and leader role. Mosey (1970) categorized developmental group interaction levels as parallel, project, egocentric cooperative level, cooperative, and mature. In a developmental hierarchy, from more directive to group-centered, a more mature group is able to direct itself and support its needs (Box 37.3). The members' flexibility in meeting the demands of the task and setting demonstrates its adaptability, maturity, and ability to function. A parallel, less mature group is less able to carry out the task and support emotional needs. At times, a group task demands different levels of interaction.

The task of selecting activities and materials is an important leader function that relates to the symbolic meanings of group processes. When activities are selected that lack meaning for the group members, interest and motivation dwindle. As a leader, operating from one's own cultural orientation alone is ethnocentric rather than group-centered or client-centered. Such ethnocentrism is illustrated when a group leader plans holiday activities around Christian holidays and no one takes initiative in the group. Conversely, an example of a culturally responsive

CASE STUDY: *Silence and Competition*

A task-oriented process group focuses on helping members learn more adaptive ways of socially participating in a group through analysis of the relationships between process, product, and interaction. Suppose that in a task-oriented process group, a subgroup of three people initiated the planning of group games for subsequent sessions. No one in the larger group disagreed with the plan until two members expressed apathy and boredom after three weeks of parallel "icebreaker" question-and-answer-type activities with no group interaction required. The subgroup members expressed shock and anger that no one had spoken up earlier. "Well if you felt that way, why didn't you say so?" one member of the subgroup said. There was silence in the room.

What does the silence symbolize for the group and its members? It is possible that members had not voiced their disagreement for fear of rejection. They might have been acting out, or acting in, because feelings of competition with the more active members had been aroused. The choice of a parallel activity was also of importance. In a parallel activity, there is no competition. Members work side by side in an activity that is structured to guarantee a win-win situation for all. Again, it is likely that the group was avoiding competition. By suggesting the parallel activity, the active members were in **collusion** with the silent members to avoid competition. Only when the two members who expressed apathy and boredom gave voice to their concerns did competition emerge in an overt manner.

When the factors that are operating for the group to so fiercely avoid competition with each other and with the leaders are examined at level of process, this yields a lot of information about the group. At the structural level of group process, one might find an imbalance of group membership roles. Member role taking in the social-emotional realm, such as encouraging, compromising, gatekeeping, and harmonizing, would help the group to explore likes, dislikes, and conflicts. In this group, the members are leaning toward task-oriented roles such as information giving, coordinating, and energizing the group into action. Psychodynamic aspects of group process call attention to underlying or latent issues. **Antigroup** forces (Nitsun, 1996, 2002), psychodynamic in nature, suggest that feelings of rivalry and envy toward other group members or the leaders as well as fear of rejection are possible factors contributing to the group reaction.

The gender of members is also relevant to the group's process around competition. In the scenario described above, all the members are female. There might be a strong positive bias toward win-win in a task versus win-over. If men were introduced into the process, it is possible that the group would experience different scenarios, such as more comfort with overt competition. Furthermore, there is the possibility that in the mixed group, the role balance would shift toward gender stereotypes. The latent potential for women to assume more social-emotional caretaking roles and the men to assume more task roles deserves examination.

MOSEY'S DEVELOPMENTAL GROUP LEVELS (DONOHUE, 2003; MOSEY, 1970)

- **Parallel:** Minimal sharing of task; leader emotionally supports and structures task
- **Project:** Short-term sharable task; leader helps with task selection and cooperation
- **Egocentric cooperative:** Joint interaction with self-interest; leader role model; leader assumes missing roles and acts as resource person
- **Cooperative:** Members able to assume social-emotional roles and mutual need satisfaction; leader acts as consultant
- **Mature:** Members able to balance roles to support and maintain task without supervision; leadership is shared; therapist is peer

activity selection is adolescents in a cooking group selecting and sharing foods that are representative of their culture or cultures.

THE MEANING OF PROCESS

Whether they are short-term or long-term, groups change over time. A variety of interpersonal concerns emerge as groups evolve. The **phases of group development** provide a conceptual model of the evolution of a group issues. Bion (1959) proposed that tensions emerge in a group and their resolution forms the basis and process of group development. He identified three stages and processes of coping with tension: (1) fight or flight, (2) dependence and counterdependence on the leader, and (3) pairing (Box 37.4). The group becomes a working group as members resolve the tensions inherent in the task of operating as a group. Similarly, Tuckman (1965) identified four

TENSION COPING BEHAVIORS (BION, 1959)

- **Fight or flight:** Hostile and hierarchical; time spent selecting enemies and attacking them
- **Dependency:** Insists leader protect and expresses dissatisfaction with adequacy for task
- **Pairing:** Failure to develop group cohesiveness; pairs dominate

TUCKMAN'S (1965) STAGES OF GROUP DEVELOPMENT

- **Forming:** Uncertainty of role in group, purpose, and procedures of group
- **Storming:** Conflict and rebellion in group as members resist group influence
- **Norming:** Group discovers ways to work together, set norms to enable cohesiveness
- **Performing:** Group is flexible in ways of working together to achieve aims

stages of group development: (1) forming, (2) storming, (3) norming, and (4) performing (Box 37.5). The group progresses as members resolve and adjust to underlying emotional issues in relation to each other and the leader. Progress waxes and wanes as stresses emerge in the group, such as those occurring with the addition of a new member or loss of a long-standing member. Although the notion of schemes of group development has been an issue of debate, there is substantial empirical evidence to support the emergence of phases in a group (MacKenzie, 1994). The phases are supported by a systems-centered model (Agazarian & Gantt, 2003) and have relevance to the leader function and intervention strategies in facilitating functional group action (Howe & Schwartzberg, 2001). In a system-centered model, the group is viewed as an organized body of mutually dependent ingredient parts. "It is the interactive system that changes through the developmental stages, not the individual group members" (Howe & Schwartzberg, 2001, p. 22). In spite of verification, the empirical evidence has not quieted the debate over whether or not distinct phases of group development truly exist.

MICRO AND MACRO LEVELS OF PROCESS

Micro Level

Interpersonal difficulties can emerge between individuals at the structural or micro level of process. It is inevitable that all occupation-focused groups lack cohesiveness at one time or another, depending on the group's maturity. The members might be unable to make a group decision or carry out a plan. In groups that are structured for the purpose of self-examination and evaluating performance, such as a task-oriented process group, part of the work of the group is to identify structural problems in the group. Members' fear of ridicule, for example, might lead to premature decision making or sole reliance on the leader for ideas. Lippitt (1961) long ago identified factors that facilitate group decision making. These include clear definition of the problem,

CASE STUDY: *Late or Absent Members*

Week after week, a member arrives late. No one in the group says anything to the late member. The member gives excuses such as the traffic and the weather. It is in the group contract, a written agreement, that members attend group regularly and arrive on time. The leader confronts the group member about being late. Members express anger at the leader for being too harsh, for singling out the chronically late member, and for embarrassing the person.

In this scenario, it is important to ask about the group's phase of development. Are the late member's behavior and the group's reaction evidence of storming and the beginning of pulls toward independence? Are members avoiding a direct confrontation with the leader about limits being imposed? As members solidify around a peer, the leader, by keeping to boundaries, helps the group to become cohesive and self-directing. Trust is more likely to be established when limits are reasonable and consistently upheld by the leader and group. When boundaries are not maintained, the behavior is explored and examined. Such exploration involves discovering conscious and unconscious motives for behavior, including following and not following expectations. At times, a member might be asked to leave a group if the behavior is detrimental to the process and to the individual and/or the group. Such a situation is bound to test the leader's vulnerability to rejection and desire to be helpful.

---

clear understanding of who is responsible for the decision, effective communication for producing ideas, appropriate group size for decision making, means for testing different alternative decisions, commitment to the decision, commitment of the leader to the decision-making process, and agreement on the procedures and methods for decision making before deliberations on the issue (Lippitt, 1961). Lippitt's factors set forth clear structural parameters and can assist in decision making in task-oriented groups.

Macro Level

At the macro or psychodynamic level, the member's covert or latent conflicts, wishes, and unknown fantasies emerge in the form of behaviors. Underlying the behavior are negative attitudes toward the group that have been characterized as **antigroup** forces (Nitsun, 1996). If these forces are not recognized or contained, they can interfere with the group's process.

According to Nitsun (2002), antigroup processes that emerge include threat to privacy of self and psychic survival; idealization of the one-to-one relationship; communication failures, particularly empathy and attunement in groups; fears around sexual exposure or rejection; arousal of feelings of rivalry and envy with the therapist and between members; attacks on connectedness of thoughts, feelings, and actions; and projective identification. These group processes can be expected to surface in psychotherapy groups, and when explored, they can form a basis for development. Antigroup forces occur at the level of the individual, the subgroup, and the group as a whole. These forces can be destructive or challenging and are widespread in larger groups such as institutions and organizations (Nitsun, 2002).

In occupational therapy groups, the antigroup forces often take the form of subgrouping, scapegoating, role lock, anger, withdrawal or silence, and competition. **Subgroups** are clusters or dyads of members that subconsciously band together to avoid something displeasing. They emerge when the emotional task is anxiety-provoking (Bion, 1959). The scapegoat receives the projection of unwanted parts of individuals in the group or operates through **projective identification**. "Projective identification is an unconscious interpersonal transaction in which one person or subgroup finds a willing container for unwanted projections; the recipient then identifies with these projections, that is, the disowned parts of the projector" (Weber & Gans, 2003, p. 408). **Scapegoating** is putting the unwanted and disavowed feelings of group members into one member (Weber & Gans, 2003). **Role lock** is the group's confining a member's participation to a restricted part of that individual (Weber & Gans, 2003). For example, in an occupational therapy group, the members might rely solely on one member to bring supplies and to start the activity or a discussion. The initiator who is cast into this role misses opportunities to be on the receiving end, and the other members are locked into passive, dependent behaviors. Ultimately, such role lock leads to dissatisfaction for all the members and a breakdown in the group process and task completion.

LEADER RESPONSES

"Countertransference responses in therapists vitally need to be understood and managed. The Anti-Group tends to arouse feelings of incompetence, failure, helplessness, and anger in the group therapist, and it is crucial in such a situation that the therapist has a professional support system and access to regular supervision" (Nitsun, 2002, p. 464). These responses are both subjective and objective reactions to group members.

The leader response might be one of shame (Weber & Gans, 2003) or the coconstruction of the difficult patient (Gans & Alonso, 1998). "Usually when people refer to the difficult patients, they speak of how such patients: (a) promote or impede group work; (b) accept or fail to accept

---

CASE STUDY: *Subgroup Meetings Outside of Group*

To promote group unity, group members are told that as part of the group contract, it is preferred that discussions about the group not occur outside of scheduled sessions. If members do have contact outside the group, it is expected that the events and discussion be brought back to the group. For example, a member casually mentions having invited another member to her home and says that her mother was so glad to meet a group member. A silence ensues. The event occurs during one of the earlier group sessions of this time-limited group.

Many issues can be underlying the group's process. Consider reasons for the subgroup formation. Were the two members expressing something on behalf of the other members of the group? By having the outside contact and bringing it back to the group, were the two members testing the group's and leader's reactions? Fears of being forced out of the group and the wish to be held and contained by the group are stirred. The leader is challenged to bridge the emotional concerns to discourage a split in the group. Such an encounter forces the leader to avoid taking sides or acting out through the subgroups.

---

feedback from other group members and/or the leader(s), (c) come to symbolize and amplify the most problematic parts of each member, (d) and challenge the members' and the leader's trustworthiness, empathic capacity, and competence" (Gans & Alonso, 1998, p. 314).

Therapist examination of **countertransference** yields understanding of the subjective and objective. In the case of subjective countertransference, the therapist's unexamined projections of himself or herself are seen in the patient. The therapist's reaction is based on his or her own response (Ormont, 1991). In objective countertransference, the patient elicits a common induced emotional response across individuals that is not an idiosyncratic reaction of the therapist. Weber and Gans (2003) note that "four common challenges that can evoke countertransference difficulties and produce therapist shame include (1) collusion with role lock or scapegoating, (2) containing and detoxifying noxious projective identifications, (3) negative transference, and (4) idealization of the therapist" (p. 407). **Transference** can be negative or positive. The group leader experiences the projected or unwanted parts of the members at the level of the group or individuals.

A violation of confidentiality calls into question trust of the leader and fellow members. Furthermore, one can ask what role the "violator" plays for the group. There is a risk that he or she will become the scapegoat or target for hostility and distrust. Should the leader not address the member's breach, the boundaries of the group are weakened, trust is unlikely to be established, and the group is likely to dissolve. Examination of member transference

relative to past violations as well as leader self-reflection of countertransference could bolster the group and shore up the boundaries necessary for emotional safety.

It is important for leaders to examine their own behaviors so that interventions are fully centered on the member rather than in fulfilling the leader's own needs. Weber and Gans (2003) describe the ego ideal as being all knowing, all loving, and all powerful. Because therapists can never achieve that perfection, they are bound at times to feel inadequate. These feelings can be particularly acute in the new therapist and may be unconscious. By unconsciously acting out through their own behaviors, leaders can contribute to problems in group process by the construction of difficult members (Gans & Alonso, 1998). Gans and Alonso describe leader actions that can result in the creation of problematical group members. "These include (a) faulty patient selection; (b) inept or harmful handling of boundary violations, scapegoating, and group norms; (c) inability or unwillingness to acknowledge mistakes; (d) refusal to be a lightning rod for negative feelings; (e) failure to set limits on members' expression of sado-masochism; and (f) failure to accept one's own limits as they affect clinical practice during the inevitable, painful vicissitudes that punctuate one's professional career and personal life" (1998, pp. 316–317).

Occupational therapy practitioners may participate in or lead many types of groups. Group processes such as phases of group development, group member roles, and covert interpersonal and intrapersonal dynamics affect all groups. When understood, the leader's countertransference

---

CASE STUDY: *Breach of Confidentiality*

In the first meeting of a group, the leader explains that material in the group stays in the group and is not to be shared outside of the session. Immediately afterward, a member comments, "Remember in the last group, one of the girls, what was her name, Mary Smith, broke up with

her boyfriend and cried all the time?" The group begins to question the member about circumstances and presses to know more about the incident. The leader is appalled and angry with the group member for revealing the name and circumstances of another member.

CASE STUDY: *Coleader Colludes with Group*

In an occupational therapy student supervision group, during one leader's absence, the coleader brings a game for the group to play rather than planning process with the group, which involves discussing alternatives for the use of the group time. When the absent leader returns, she expresses confusion about the group's agenda. The group members are silent and play the game until the "colluding coleader" expresses exasperation at not knowing how to follow the rules of the group.

The change in direction suggests competition between the leaders and unconscious acting out. Is the coleader changing the process to gain favor or approval from the group? Is the division symbolic of subgroups within the group or expressed anger in the group? Perhaps the introduction of more structure through the use of the game is an attempt to ease the group's and coleader's anxieties about the absence of the other leader. The group might be using the structure of the game as a means to avoid feelings of loss.

CASE STUDY: *Group Member Refuses to Participate in Activity*

A group member will participate only when working by the leader's side. As soon as the leader attempts to help someone else, this person leaves the room or sits in a corner and sulks.

The member's behavior raises questions about the suitability of the group for this individual. The member's group interaction skills might not be at a developmental level at which he or she can share attention. The group task might also be faulty, as the member is unable to successfully engage in the activity without one-on-one support. The reasons for faulty patient or activity selection need examination. Such a mismatch can stem from within the leader as well as from agency pressures for member inclusion in group programs.

COMMENTARY ON THE EVIDENCE

Group Process

Evidence suggests that occupational therapy–related intervention in groups is effective in addressing outcomes in body function (e.g., mental functions) and occupational performance areas and skills such as social participation and communication/interaction skills (Howe & Schwartzberg, 2001). Evidence-based techniques vary depending on the desired outcomes and client problem. Intervention for performance areas and skills conducted in a group setting may result in greater client satisfaction and compliance with intervention regimes (Howe & Schwartzberg, 2001). Because the range of skills addressed is so varied, it is best to examine the literature specific to the client factor and outcome in question.

The range of concerns related to group process is very broad and also dependent on group context, setting, and population. Studies of interest to support practice include the emergence of phases of group development (Agazarian & Gantt, 2003), group size and its influence on group accomplishment (Howe & Schwartzberg, 2001; Yalom & Leszcz, 2005), and the importance of self-initiated and purposeful action in a group. There is a need to expand the evidence in all areas of occupational therapy intervention in which group process is applied to specific client problems or as a means to enhance problem-specific methodologies.

A good example of such needed research is a randomized controlled trial that was conducted to evaluate the efficacy of an eight-session, group-based program designed to reduce fear of falling and increase activity levels among older adults (Peterson, 2003; Tennstedt et al., 1998). "Data collected over 12 months showed that compared with control subjects, intervention subjects experiences increased social participation and community mobility" (Peterson, 2003, p. 12).

reactions can influence strategies that are used to enhance group effectiveness. These group processes are important consideration for facilitating effective groups. Understanding the dynamics that influence group cohesiveness can lead to more successful leadership of small groups in occupational therapy.

PROVOCATIVE QUESTIONS

1. Recall a time when you were in a task group and experienced strong emotions. What was happening in the group at the time? What feelings did you experience—for example, anger, frustration, sadness, jealousy, envy? Consider the range of feelings that might have been hidden or covert and those that were overt or known to yourself and others.

2. In the situation you recalled in question 1, how did you respond to others in the group? What feelings might have been in conflict? Consider analogous feelings, such as anger and sadness, anxiety, and calmness. What group membership roles do you tend to assume? What is the underlying psychological or social gain? For example, do you tend to be a mediator in a group to avoid conflict or competition?

3. Return to your situation described in question 1. Alter the circumstance in the group. For example, you might change the number of people in the group, the gender of the members, the task, the rewards, and the leaders. How might the group process and role in the group change? Consider the following illustration. It is the first day of class, and your professor asks students to decide when they would like to present their final project to the class. A student whom you regard as typically aggressive and self-centered picks all the dates that work best for you. By the time you have the courage to say what date you prefer, the only dates left conflict with a fieldwork assignment. You feel angry and helpless. Rather than sulking, you could alter the process by suggesting that students rank order their preferences and trade dates with each other, for example.

COMMUNICATION IN OCCUPATIONAL THERAPY

"Say what you mean and mean what you say."

George S. Patton

Team Interaction Models and Team Communication

ELLEN S. COHN

66 The path to greatness is along with others. 99

—BALTASAR GRACION, SPANISH PRIEST (1637)

Learning Objectives

After reading this chapter, you will be able to:

1. Describe the benefits of a team approach to intervention.
2. Describe the roles of medical, rehabilitation, and educational professionals.
3. Describe the communication dynamics of team process.

TEAMS AND TEAMWORK

In the often-cited poem about Hinduism, "The Blind Men and the Elephant," John Godfrey Saxe described the plight of six men, all blind, who happened on an elephant. The first man, feeling the elephant's side, reported that the animal was like a wall. The second, feeling the tusk, interpreted the creature to be like a spear. The third, finding its trunk, declared it to be like a snake, and so on. Thus, when each observer stated his opinion of the elephant, "each was partly in the right, and all were in the wrong!" (Saxe, 1871, p. 260). Herein lies the concept underlying the use of team communication. Although each member, representing a different perspective, is hardly blind, a single way of observing limits the ability to comprehend the whole.

It is the combined vision, evaluation, and coordinated intervention plan that provides a complete picture of the whole client receiving intervention.

For most areas of practice, interdisciplinary team interactions are the norm. Successful intervention involves a collaborative and mutual process during which practitioners and clients develop the care plan together (Golin & Duncanis, 1981; Humphry, Gonzalez, & Taylor, 1993; Leff & Walizer, 1992). According to Parham (1987), occupational therapists are "concerned with understanding the occupations of human beings, the ways in which people organize the activities that fill their lives and give their lives meaning" (p. 555). To understand how a particular client experiences illness or disability in the context of his or her occupations and daily life, the occupational therapy practitioner needs to collaborate with other members of the team involved in providing care for that client.

The team comprises a variety of different specialists who have different backgrounds, training, values, and worldviews and sometimes different goals. These specialists work together in different configurations, depending on the client's needs, the type of setting in which the intervention is provided, and available resources. The intervention team for a child with traumatic brain injury returning to elementary school after two months in a rehabilitation hospital might include the child and his or her parents, a special educator, a speech-language pathologist, an occupational therapist, an adapted physical education teacher, and a school nurse. An older adult who recently had a mild stroke affecting her vision and who lives in low-income housing might receive intervention services from an occupational therapist, an optometrist, a physical therapist, and a social worker. Practitioners providing intervention to communities might work with teams of people representing local businesses, voluntary citizen's organizations, or local government officials. Each team member addresses the client's concerns from a unique perspective, and all perspectives are then coordinated to structure the client care plan. It is assumed that this coordinated perspective will make a difference in the ultimate outcome for the recipient of the care plan (Crepeau, 1994a, 1994b; Unsworth, Thomas, & Greenwood, 1995).

Ideally, interdisciplinary team members share a common concept of the client's concerns and a common philosophy of intervention. They synthesize the diverse information gathered from their own evaluations and those of outside consultants, and they work together to formulate and implement a comprehensive care plan based on the available data. Most important, the team should act as a functional unit whose members are willing to learn from each other and modify their own opinions, when appropriate, on the basis of the combined observations and expertise of the entire group (Perlmutter, Bailey, & Netting, 2001). The advantages of a team approach are a more holistic approach to client care, integrated interventions, the reduction or elimination of duplicated services and fragmentation or gaps in care, and quicker and better-informed decisions for client plans (Stancliff, 1995).

Historically, health care teams have generated a client's care plan behind closed doors, without the client's input, and then shared their plans with the client. In current practice, however, additional voices are influencing the team process. Health professionals now espouse incorporation of the client as a member of the team and view this as crucial to the eventual success of the care plan (Baum, 1998; Crepeau, 1994a, 1994b). Moreover, the Individuals with Disabilities Education Improvement Act, IDEA 2004 (P.L. 108-446), federal legislation outlining the educational requirement for children with special needs, clearly specifies that students and their parents or caregivers must be involved in team decisions regarding the student's needs. In the managed care environment, which focuses on both cost containment and quality of care, the third-party payer's perspective is increasingly considered to be another crucial factor in the team's decision-making process.

An understanding of the potential contributions of the various people and professionals involved in the client's life enables the practitioner to develop a more meaningful plan for each client (Figure 38.1). The members of the team have interrelated functions. Depending on the practice environment, the occupational therapy practitioner's interactions with other professionals and with the important people in the client's life vary. In a medical setting, such as an acute care hospital or a rehabilitation unit, the team members might operate under a physician's order, and practitioners might interact with team members numerous times a day. Alternatively, a practitioner who is in private practice or employed by a home-care agency might not have frequent contact with other specialists but might have more repeated contact with family members or other significant people in the client's life.

FIGURE 38.1   Team meetings foster collaboration and integrated intervention planning.

Regardless of the environment, occupational therapy practitioners need to be aware of the roles of the other members of the team in order to be clear about the contributions that occupational therapy can make and how everyone can work together for the client's benefit. Therefore, occupational therapy practitioners need to interpret their role and contribution to the intervention team, for it is never safe to assume that other members of any particular team have a full understanding of the potential contributions of occupational therapy. Consider, for example, Rose's story in the following case study.

TEAM INTERACTION MODELS

Each client usually has an identified case manager or team leader. The case manager is the designated person on whom clients and their family members can consistently rely to explain, clarify, or acquire necessary information. This case manager may also serve as the client's ombudsman. The leadership of the team or the case management may change over time, according to the identified concerns of a particular client, the members of the team, the nature of the task, and the structure of the organization. In a traditional medical model, the physician is often the leader of the team. Today, especially in rehabilitative, long-term care, community-based, or educational settings, a therapist, social worker, nurse, special service coordinator, or teacher may lead or coordinate the team and simultaneously serve as the case manager.

Teams may be organized according to a multidisciplinary, interdisciplinary, or transdisciplinary model. Often, however, a team moves from one model to another and functions in its own unique variation of the classic models. In the multidisciplinary team approach, team members work side by side. Each member has a clearly defined role with specific areas of responsibility; team members understand each others' professional scope of practice and rely on each team member to address their area of concern. Although evaluation, planning, and therapy take place independently, the team members may communicate with each other on a regular basis or through the client's record or chart. Generally, families and clients meet with the team members of each discipline separately. Examples of this type of team interaction might be seen in an outpatient situation when a person is receiving intervention services from a home health aide, occupational therapy, and physical therapy.

In an interdisciplinary team approach, team members share responsibility for providing services, often supporting the goals of other team members. They conduct separate evaluations but share the results to develop an integrated and coordinated care plan. The team members have substantial knowledge of each other's discipline and begin to understand the perspective of others. Clients and families or other significant people in clients' lives meet with the team or a representative of the team, such as the team leader or case manager. Effective interdisciplinary teams communicate to resolve conflicts and make shared decisions. Common examples of interdisciplinary teams are found in rehabilitation hospitals, where professionals from numerous disciplines (the client and caregivers, occupational therapy, speech-language pathology, physical therapy, nutrition, social work, therapeutic recreation, nursing, and medicine) meet to share perspectives and develop a coordinated intervention plan.

CASE STUDY: *Rose: An Interdisciplinary Approach to Planning for Transition to Home for a Woman with Multiple Traumas*

Rose is a 72-year-old who was recently hospitalized after experiencing multiple traumas from an automobile accident. She is now receiving occupational therapy services in her home. Although her husband is devoted to her, he is unable to help her maintain the home. A social worker is available to consult with the intervention team. Together, the occupational therapist, the client, her husband, and their adult children, along with the social worker, determined that seeking the services of a Meals-on-Wheels program would alleviate the pressure of preparing major meals. Additionally, Rose's adult children, all of whom live at a distance, have offered to pay for a house cleaning service for three months while she recovers. This team decision-making process helped the occupational therapist to determine the focus of occupational therapy intervention. With Rose's most strenuous homemaking duties alleviated, the occupational therapist was able to focus on helping Rose to regain and monitor her strength and endurance so that she could completely manage her self-care and prepare light meals, as well as joining her husband at their weekly singing group. With the assistance of the intervention team, occupational therapy focused on meaningful activities for Rose and her husband.

Although practically every medical, health, or educational professional may be called on to provide services to address the range of client conditions seen by occupational therapy practitioners, the professionals listed in Table 38.1 may be especially relevant to occupational therapy intervention (Wachtel & Compart, 1996). The Websites of professional associations provide overviews of the qualifications of various professionals with whom occupational therapy practitioners are likely to work.

TABLE 38.1 MEDICAL, REHABILITATION, AND EDUCATIONAL PROFESSIONALS AND PROFESSIONAL ASSOCIATIONS

Professionals	Associations
Adapted physical educator: Adapts sporting equipment and games for individuals with special needs.	National Consortium for Physical Education and Recreation for Individuals with Disabilities (NCPERID): http://www.uwlax.edu/sah/ncperid
Administrator: Applies and enforces federal, state, and local laws that regulate finances, standards, and environments for most health and educational programs; has valuable expertise in management of personnel, space, and finances.	*School administrator:* American Association of School Administrators (ASA): http://www.aasa.org *Hospital administrator:* American Hospital Association (AHA): http://www.aha.org
Audiologist: Specializes in diagnosis and treatment of hearing impairments; administers a variety of tests to determine hearing level and site of damage to the auditory system; recommends hearing aids and other assistive devices to enhance residual hearing loss or the need for special training.	American Academy of Audiology (AAA): http://www.audiology.org
Biomedical engineer: Specializes in the application of scientific theory and technology to the development of devices and techniques for medical treatment, rehabilitation, and research; provides technical expertise in recommendation of commercial products and the modifications of existing devices or the design and fabrication of custom equipment or adjusted environments.	Biomedical Engineering Society (BES) http://www.bmes.org
Chaplain: Focuses on religious and spiritual needs of clients; provides nondenominational individual and family counseling; offers special services.	Association of Professional Chaplains (APC): http://www.professionalchaplains.org
Optometrist: Examines, diagnoses, treats, and manages diseases, injuries, and disorders of the visual system, the eye, and associated structures and identifies related systemic conditions affecting the eye.	American Optometric Association (AOA): http://www.aoa.org
Orthotist and prosthetist: Orthotist makes and fits braces to support or correct body parts weakened by disease, injury, or congenital deformity or to help prevent deformities. Prosthetist designs and fabricates artificial limbs, with special attention to enhancing fit, function, and appearance.	American Orthotic & Prosthetic Association (AOPA): www.ama-assn.org
Nurse: Provides goal-directed, personalized care that encompasses preventive, maintenance, and restorative aspects of nursing; administers medication and instructs client and significant others in care management and health maintenance programs.	American Nurses Association (ANA): http://www.nursingworld.org
Nutritionist: Plans food and nutrition programs and supervises the preparation and serving of meals; helps to prevent and treat illnesses by promoting healthy eating habits and recommending dietary modifications, such as the use of less salt for those with high blood pressure or the reduction of fat and sugar intake for those who are overweight.	American Dietetic Association (ADA): http://www.eatright.org
Physical therapist: Evaluates physical capacities and limitations; administers treatment designed to alleviate pain, correct or minimize deformity, increase strength and mobility, and improve general health.	American Physical Therapy Association (APTA): http://www.apta.org

Continued

TABLE 38.1   MEDICAL, REHABILITATION, AND EDUCATIONAL PROFESSIONALS AND PROFESSIONAL ASSOCIATIONS   *Continued*

Professionals	Associations
Physicians (specialists): Usually specialists to whom a client has been referred by the primary-care physician (e.g., orthopedists, ophthalmologists, neurologists, cardiologists, physiatrists, psychiatrists).	American Medical Association (AMA): www.ama-assn.org
Psychologist: Provides psychological, projective, and behavioral assessments; provides individual, couple, family, and group psychotherapy related to behavioral or adjustment issues.	American Psychological Association (APA): http://www.apa.org/
Rehabilitation counselor: Assists individuals with physical, mental, cognitive, or sensory disabilities to become or remain self-sufficient, productive citizens; helps clients to cope with societal and personal problems, plan careers, and find and keep satisfying jobs.	National Rehabilitation Counseling Association (NRCA): http://nrca-net.org
Respiratory therapist (inhalation therapist): Administers oxygen and mists for medical purposes; provides oxygen assessment programs and client education.	American Association of Respiratory Care (AARC): http://www.aarc.org
Social worker: Assists client, family, or other important people in the client's life to achieve a maximal level of social and emotional functioning; provides client and family counseling, discharge planning, and education on entitlements and other available resources; assists in identifying transportation and attendant care resources.	National Association of Social Workers (NASW): http://www.socialworkers.org
Special educator: Serves as a teacher of children with unusually high intellectual potential or children who live with mental illness, learning disabilities, or developmental deviations; may have advanced skills in teaching children who are blind, deaf, emotionally disturbed, developmentally delayed, or have physical disabilities.	National Association of Special Education Teachers (NASET): http://www.naset.org
Speech-language pathologist: Specializes in speech disorders, the development of language and speech production, the physiology of speech, theories, and measurement of hearing and phonetics.	American Speech-Language-Hearing Association (ASHA): http://www.asha.org
Teacher: Certified to provide education at the early childhood, kindergarten, elementary, secondary, or high school level.	National Education Association (NEA): http://www.nea.org
Therapeutic recreation specialist (recreation therapist): Facilitates the enjoyable use of leisure time to promote mental and physical well-being; uses social and recreational activities to aid in adjustment to disability and participation in community activities.	American Therapeutic Recreation Association: http://www.atra-tr.org

Practitioners working in schools also work in interdisciplinary teams, often with teachers, school administrators, and perhaps an adapted physical educator, speech-language pathologist, psychologist, or classroom aide.

In a transdisciplinary team approach, team members commit to teaching, learning, and working across disciplinary boundaries to plan and provide integrated services. The evaluation is planned, implemented, and summarized by the team as a whole. The team assimilates the perspectives of the various team members to make joint decisions. Traditional role boundaries are crossed, and the skills of other disciplines are integrated into a total care plan. This approach requires that professionals share discipline-related information. The client typically interacts with one professional, who consults with other professionals on the team to communicate a shared perspective to the client and carries out the recommendations and interventions of the entire team. Transdisciplinary teams are sometimes found in early intervention settings in which all team members evaluate a child in an arena model. One team member interacts with the child, while other team members observe the child and interact with the parents, seeking help and interpretation of the child's behavior. After such an evaluation, the entire team synthesizes the evaluation results to identify expected outcomes and develop specific interventions that are implemented by one of the team members. This approach reduces duplication and potential fragmentation of services.

CREATING SHARED MEANING AND A COMMON LANGUAGE

Professionals and clients may have different viewpoints or priorities for intervention, or they may have the same goals yet differ in the meaning of the goals or the approach to take for reaching goals. Therefore, it is essential for the team members to develop shared meaning about the client's entire condition. For the intervention to be effective, the team must understand each client's (Crepeau, 1994a; Salisbury, 1992):

◆ Beliefs
◆ Attitudes
◆ Ways of making meaning of his or her life world
◆ Knowledge of his or her condition
◆ Expectancies for the future
◆ Expectancies about treatment

The constructionist process, as described by Buckholdt and Gubrium (1979) and Crepeau (1994a, 1994b), involves the individual reasoning of the team members and the collective reasoning of the group. Formal lines of communication and methods for sharing these interpretations often develop through team meetings, collaborative intervention sessions, written evaluations, and progress notes. Each team member makes his or her own interpretation of the client's lived experience and then articulates this interpretation to the other team members. The team collectively reconstructs the interpretation to create a unified image from the diversity of their individual perspectives. Through this construc-

tionist process, team members discover, interpret, and negotiate their understanding of the client by "sorting out conflicting data to arrive at a common definition of the problems faced by the patient" (Crepeau, 1994b, p. 161).

To develop a cohesive treatment team that uses a constructionist process, the team must focus its energy and creativity to establish a shared mission. Only in a climate of mutual trust and respect can a group of people with diverse perspectives develop into a cohesive team (Zenger, Musselwhite, Hurson, & Perrin, 1994). Thus, it is important to acknowledge that team building is a developmental process; it takes time and energy to learn about each member's values, goals, and communication style (Blechert, Christiansen, & Kari, 1987).

Although teams may have different needs at different times, Blechert and colleagues (1987) found that team development can be described in terms of life stages. In the first stage, team members explore and define their roles within the context of the team and work setting. Each team member identifies his or her area of expertise and interest, thereby defining each member's unique contribution. Once the team has worked together, adjustment and rearrangement of roles might be necessary to progress to the next stage. Finally, as team members redefine their roles and learn to value each other, they begin to think about issues from multiple points of view. When functioning well, the team members are able to see the issues as a whole. Similar to the blind men with the elephant, the image that the team develops is broader and richer when multiple perspectives are shared to construct a unified image.

CASE STUDY: *Interdisciplinary Communication in a Community Residence*

Coordinating an interdisciplinary approach to provide intervention within a community residence for young adults with persistent mental illness requires ongoing communication among all the members and staff in the community residence. The occupational therapist, nutritionist, and clients of the group home designed an intervention to help the clients establish healthy habits related to eating and increasing physical exercise in their daily lives. The clients and therapist designed a daily walking program for the clients, but the staff at the residence repeatedly served high-calorie snacks or invited the clients to join them in watching a favorite television program during the designated walking time.

The occupational therapist realized that for the intervention to be implemented successfully, the entire staff needed to collaborate in the program design. To build consensus among all the staff and clients in the residence, the therapist scheduled a meeting with the entire residential community

to set group goals and explore everyone's ideas for program success. Collectively, the members of the residential community, staff and clients, generated a list of potential problems and barriers to the success of the program. With the barriers made explicit, the group was then able to identify strategies to promote the program. The staff decided to post a chart in the communal living room to document the amount of time and distance covered in daily walks. The clients decided to plan a special outing to a favorite water slide park for all clients who reached the goal of walking 10 miles by the end of the month. Two staff member who were interested in exercise volunteered to be the "Exercise Group" leaders, and the entire community voted on a new name for the group: "Step in Time." The trip to the water slide park required use of the agency van, and the director of the residence had to complete the paperwork for approval to use the van. The intervention would be successful only if everyone shared the common goal.

PRACTICE DILEMMA

COMMUNICATING THE ROLE OF OCCUPATIONAL THERAPY

Carmen, a registered occupational therapist, has worked in a local early childhood program for the last five years. During this time, Carmen and the psychologist collaborated to colead a social skills group for children with autism spectrum disorders. During a recent reorganization of the program, the psychologist was reassigned to another program in the district. The new psychologist has never worked with an occupational therapist and does not understand Carmen's con-tribution to the group. The new psychologist and Carmen do not agree about a particular child's readiness to participate in the social skills group.

Questions

1. How might Carmen communicate the role of occupational therapy to the new psychologist?
2. How might Carmen and the psychologist develop a "common language" to communicate?

PROVOCATIVE QUESTIONS

1. Why is it essential for an intervention team to develop consensus about a client's needs?
2. What strategies might you use if the intervention team you were working with did not value each team member's expertise?
3. Some would argue that a transdisciplinary team is effective because the client has to work with only one person. Others argue that it is inappropriate for a professional to provide services "outside" of his or her professional discipline. What are your thoughts about using a transdisciplinary approach in an early-intervention setting?

Documentation in Practice

KAREN M. SAMES

“It's not what you tell them . . . it's what they hear.”

—RED AUERBACH

Learning Objectives

After reading this chapter, you will be able to:

1. Identify the primary reasons for documentation of occupational therapy services
2. Describe the types of clinical, educational, and administrative documentation used in occupational therapy practice
3. Identify the key features of occupational therapy documentations in clinical and educational settings

INTRODUCTION

Occupational therapy practitioners communicate with many different types of people on a daily basis. They provide instructions for home programs to clients and their caregivers. They inform other professionals on the care team about the client's progress in occupational therapy. They write letters to foundations seeking funding for new programs. This chapter will address the various audiences and types of documentation that occupational therapy practitioners may use at some point during their careers.

AUDIENCE

How one documents depends greatly on who will receive the communication—one's audience. Writers must understand the reader's background and motives (Oliu, Brausaw, & Alred, 1995). How a letter to an insurance company is worded might be very different from the way a letter to a parent or physician is worded. Documentation that is read by a physical therapist might use more precise anatomical and technical words than would an Individual Family Service Plan that is shared with the parents of a 2-year-old. Knowing who will read what is being communicated is an important aspect of effective documentation.

The potential audiences for occupational therapy documentation include the following:

◆ Medical professionals (medical doctors, nurses, psychologists, physical therapists, speech-language pathologists, social workers, case managers, quality management staff, etc.)
◆ Education professionals (teachers, principals, etc.)
◆ Lawyers, judges, and juries
◆ Accreditation agencies (JCAHO, CARF, Department of Education, etc.)
◆ Payers (HMOs, Medicare intermediaries, Medicaid reviewers, etc.) and
◆ The client or the client's guardian

Each audience reads documentation through a different lens, depending on practice setting, educational level, and cultural background (Sames, 2005).

When one is communicating with medical professionals, one needs to be very precise. A physician, for example, would not be satisfied with a diagnosis of "stroke" for a client with whom the occupational therapist is working. The physician might want to know whether the stroke was affecting the right or left side, whether it was mild or severe, and how long it has been since the stroke. Nurses need to know more than that the patient needs assistance with dressing; they need to know how much assistance and the nature of the assistance.

When one is communicating in a school setting, there is a need to focus on the educational relevance of the information. The entire team working with the child might not understand medical jargon, so educational terms are more appropriate.

Occupational therapy practitioners need to communicate with each other and with other professionals and may do so by using formal letters, memos, e-mails, or phone calls. The word choices and the tone of the writing or speech used in professional, or formal, communication are very different from those used in informal communication between friends. Professional communication requires a level of respect and formality that is not required in informal communication.

Professional communication uses complete sentences and avoids slang or emotionally charged words. Informal communication often uses slang and emotionally charged words, may use phrases, and is usually directed toward someone known by the speaker or writer. When writing appeal letters, official memos, or plans of care, the writer might or might not know the person on the receiving end of the communication. Professional titles, rather than first names, are used in professional communication. This is where first impressions count.

Formal documentation often requires compliance with specific standards. For example, the **Individuals with Disabilities Act (IDEA)** requires that specific items be included on the Individualized Education Program, and Medicare requires specific documentation elements for outpatient therapy reimbursement. The Joint Commission on Accreditation of Health Care Organizations (JCAHO) requires that certain abbreviations be avoided to minimize the likelihood of medical errors due to abbreviations that are remarkably close in appearance (JCAHO, 2004). In addition, employers might have policies or procedures that further direct the method (electronic or paper and pen), timing, placement, and word choices of the documentation. Box 39.1 contains some documentation tips that apply to all documentation.

Two points are important considerations for all documentation (Sames, 2005):

1. People form an impression of your professionalism and intelligence by reading what you write.
2. What you write can be used as evidence in a court proceeding, whether you are on trial or not.

LEGAL AND ETHICAL CONSIDERATIONS

Medical records are legal documents. Medical records can be entered as evidence in any type of legal proceeding involving **malpractice**, **fraud**, **negligence**, or **incompetence**. The occupational therapy documentation can be called into court, with or without the occupational therapist being there to explain the documentation, even years after the services were provided. What was written at or near the actual time the event or events in question occurred is stronger evidence than what a person can recall months or years after the event. To remain mindful that all documentation is legal evidence, some people mentally preface their documentation by saying to themselves "Ladies and gentlemen of the jury . . ." before putting pen to paper (Sames, 2005).

BOX 39.1   DOCUMENTATION TIPS

◆ Use correct
  ◆ Grammar
  ◆ Spelling
  ◆ Syntax
  ◆ Word choice
  ◆ Literacy level for the reader(s)
◆ Read spell-checker and grammar-checker recommendations carefully; sometimes it is better to click "Ignore" than to use what they recommend.
◆ Proofread carefully.
◆ Follow directions carefully.
◆ Have a dictionary and a writing manual handy.
◆ Write legibly (Sames, 2005).

Medicare and other government payers can review clinical documentation and client charge (billing) records at any time to determine whether fraud has been committed. If documentation is not adequate to support the charges, Medicare (and other payers) can refuse to pay for the services, and the occupational therapist responsible for documenting the services could face both civil and criminal penalties, as well as loss of certification and licensure (American Occupational Therapy Association [AOTA], 2000; Fremgen, 2002; Kornblau and Starling, 2000; Liang, 2000).

In addition to legal issues of documentation, there are ethical concerns. The AOTA Code of Ethics (2005) states in Principle 6.C that the "use of any form of communication that contains false, fraudulent, deceptive, or unfair statements or claims" is unethical. This is further clarified in the AOTA *Guidelines to the Code of Ethics:* "Occupational therapy personnel do not make deceptive, fraudulent, or misleading statements about the nature of the services they provide or the outcomes that can be expected" (AOTA, 2006, 2.1).

DOCUMENTATION IN CLINICAL SETTINGS

In hospitals, rehabilitation facilities, outpatient clinics, long-term care, mental health centers, home health, and related settings, similar types of documentation are used, although the frequency of documentation may vary. Clinical documentation generally involves reporting and interpreting the clients' responses on assessments and to interventions in a medical record. Clinical documentation is important for the following reasons:

◆ Continuity of care within the department
◆ Communication across shifts, disciplines
◆ Chronological record of care
◆ Legal record
◆ Reimbursement requirements (Sames, 2005)

It is critical that the objective information reported in the documentation be clearly differentiated from the subjective information. If a practitioner states that a client appeared depressed, that is a subjective statement. It is a conclusion drawn from the practitioner's observations. To make an objective statement, the practitioner should describe what was seen or heard that would logically lead to the conclusion that the client appeared depressed. For example, the practitioner could say, "Client stared at the floor for the entire session. She slouched forward in her chair, responded to questions with one syllable words, and did not initiate any conversations with peers."

All clinical documentation must be done in compliance with the standards of the setting as well as standards set by the profession. For example, every entry in the clinical record must be dated (AOTA, 2003). With electronic documentation, the date is automatically recorded by the sys-

tem. If the documentation is handwritten, the date must be put either at the top of the documentation or at the bottom, by the signature, whichever is the standard at the facility (AOTA, 2003). The essential features of all clinical documentation are as follows:

◆ Date of completion of report
◆ Full signature and credentials
◆ Type of document
◆ Client name and case number
◆ Acceptable abbreviations as determined by the facility
◆ Acceptable terminology as determined by the facility
◆ Corrections made with a single line through the error and initials of person who made the error are written above
◆ No use of an eraser or correction tape or fluid
◆ Record storage and disposal that complies with federal and state laws and facility procedures
◆ Protections of confidentiality
◆ Black or blue ink, never pencil (Sames, 2005)

The occupational therapy practitioner's rationale—the reasons behind the intervention—should be made clear in the documentation. For example, clients with mental health challenges might have problems in living that are not as visible as physical challenges. While people who uses wheelchairs might have difficulty with grocery shopping because they cannot reach all the shelves or push the cart while seated in a wheelchair, people with bipolar disorder might have difficulty shopping because of an inability to control impulses to buy everything and talk to everyone in the store.

Documentation of the Initiation of Occupational Therapy Services

The first type of clinical documentation reflects the first steps in the clinician-client interaction. In some settings, such as in a long-term care facility, the first step is a **screening** of all new admissions to the facility. In other settings, the first step might be an introduction, or it might be the beginning of the evaluation process.

If the client is seen for a screening or introduction prior to an **evaluation**, a short note is usually written in the medical record summarizing the conversation and/or results of the screening. The occupational therapist or occupational therapy assistant writes a short summary and indicates the next step in the intervention process.

Evaluation reports are written by occupational therapists to document the starting point of occupational therapy intervention. Evaluation reports contain factual data collected during the evaluation process and an interpretation of the evaluation findings. The need for occupational therapy services must be documented before interventions can be implemented. The report must show which occupations are limited or at risk of being limited. Typically, there will be an initial **plan of care** (care plan, treatment plan or intervention plan). This plan includes measurable,

functional, and time-limited goals for the client (Borcherding, 2000; Sames, 2005).

The AOTA (2003) guidelines for documentation identify content needs for an evaluation report. The evaluation report content is based on the *Occupational Therapy Practice Framework* (AOTA, 2002). In an acute care setting, especially for short-stay clients, a complete evaluation might not be conducted. Although AOTA recommends that a complete evaluation be conducted and documented for each client, the time constraints of certain settings might require that the occupational therapist abbreviate the evaluation process and documentation.

Because payers often make decisions about whether or not to pay for occupational therapy on the basis of the evaluation report, it must show the need for skilled occupational therapy intervention (Lemke, 2004). The documentation must contain enough information to communicate that occupational therapy is the appropriate discipline to provide the needed intervention, that it meets a medical need, and that intervention will result in change in the client's function (Lemke, 2004).

Typically, the evaluation report contains the following (AOTA, 2003; Sames, 2005):

- Identifying information and background information (e.g., client's name, age, diagnosis or condition, date of referral, date of report, **precautions**, and **contraindications**)
- Referral information (date, who referred the client, and why)
- Evaluation procedures and/or tests used
- **Occupational profile** (client's perception of the need for occupational therapy, contexts that support or hinder occupational performance, brief occupational history)
- Findings or results of the evaluation process
- An interpretation of the meaning of the findings or results that reflects the occupational needs of the client
- A plan, including goals, frequency, duration, and location of intervention
- Signature and **credentials** of the occupational therapist

Documentation of Continuing Occupational Therapy Services

In clinical settings, **progress notes**, or clinical notes, are usually written after each intervention session. These may be written in a narrative or SOAP format or on a flow sheet (Sames, 2005). Regardless of the format, this documentation must show what the client did in occupational therapy and describe the client's reaction to the intervention that was provided. The progress note should include more than a list of the activities the client engaged in during the session. A reader will want to know how client's performance has changed since the last intervention session, any functional improvements, adaptive equipment provided, and client or caregiver understanding of any instructions (Lemke, 2004; Sames, 2005).

One of the most common forms of documenting the client's progress is called a **SOAP note**. This note-writing format is used by many medical disciplines, a practice that strengthens communication among professionals. Lawrence Weed, M.D., developed the SOAP note format in the 1960s as part of a Problem-Oriented Medical Record (Borcherding, 2000; Sames, 2005). Each letter of the word SOAP represents a different component of the note (Borcherding, 2000; Sames, 2005):

S = Subjective: the subjective experience of the client, what the client says
O = Objective: the clinician's objective observations and measurements
A = Assessment: the clinician's interpretation of the meaning of the "O" section
P = Plan: description of what will happen next (frequency, duration, location)

The most difficult part of writing a SOAP note is separating the objective information from the interpretation of it (assessment). Box 39.2 shows an example of a SOAP note.

BOX 39.2

SOAP NOTE

S: "It hurts to reach items on the second shelf. No way could I reach the top shelf. I can't even put my hair in a ponytail. It just hurts too much."

O: Client reached items on the second shelf of the kitchen cabinet with her right hand, expressing discomfort throughout the range. Client did not attempt to reach items on the top shelf. Client pointed to the anterior aspect of the glenoid fossa when asked where it hurt. Scapular elevation and trunk rotation substituted for part of shoulder flexion and abduction; she never raised her arm above 80°. Client used internal rotation to place items retrieved from the shelf on the counter with no complaints. Client did not use external rotation in replacing objects on shelf, reporting severe pain using that kind of motion. She rated her pain a 9 on a 0–10 point scale.

A: Right shoulder range of motion is severely limited and very painful. Limited range of motion interferes with meal preparation, dressing, hygiene, and grooming.

P: OT 2×/wk, for 30 min outpatient sessions to instruct client in use of reacher, discuss environmental adaptation principles related to placement of objects within comfort zone, and develop a home program to facilitate regaining pain-free range of motion.

In settings in which clients are seen for an extended period of time (over 30 calendar days), an updated plan of care is written. A plan of care shows what progress has occurred since the last plan of care was written (or an explanation for lack of progress); updates goals and sets new ones; and verifies the frequency, duration, and location of continued intervention (AOTA, 2003; Sames 2005).

Documentation of Termination of Occupational Therapy Services

Once clients have met their goals or other circumstance require that occupational therapy services end, a **discontinuation summary** (discharge summary) is written (AOTA, 2003; Sames 2005). This summary includes the following:

◆ Identifying and background information
◆ Summary of the client's functional status at the initiation of occupational therapy services
◆ Summary of change in functional status at the close of occupational therapy services
◆ Recommendations for follow-up
◆ Signature, credentials, and date

DOCUMENTATION IN SCHOOL SETTINGS

Documentation in educational settings can be very different from clinical documentation, but the same documentation principles apply. Documentation in school systems can be divided into three main categories: notice and consent forms, **Individualized Family Service Plans (IFSPs)**, and **Individualized Education Programs (IEPs)** (AOTA, 1999; Sames, 2005).

Documentation of Notice and Consent

According to the Individuals with Disabilities Education Act (IDEA), notice and consent forms are required to communicate with parents or guardians of children being served by the school district. Documents may include notices of team meetings, notice and consent for evaluation or reevaluation, referral for an initial evaluation, procedural safeguards, and a report of an IFSP or IEP meeting (Sames, 2005).

Documentation of Services from Birth Through Age 2 Years

Services for infants and toddlers are described in Part C of IDEA (AOTA, 1999). IFSPs are written to address these services. Each state designates a lead agency (education, health, or human services) to serve the needs of infants and toddlers with special needs to help ready them for school. The lead agency is responsible for creating an IFSP for each child served that is tailored to the specific needs of the child and the child's family. Occupational therapists can serve as **service coordinators** (case managers) for IFSPs. The service coordinator is responsible for ensuring that the proper documentation is completed and scheduling team meetings as needed or required by IDEA. An IFSP includes the following:

◆ A summary of the child's present level of performance (physical, cognitive, communicative, social or emotional, and adaptive development)
◆ Identification of the family's concerns, priorities, and resources
◆ A summary of expected outcomes (measurable goals)
◆ Identification of early intervention services needed, including frequency, intensity, and service delivery method
◆ Identification of the child's natural environment (where services will be delivered)
◆ Date services will start and the anticipated length of services
◆ Identification of a service coordinator for the child and
◆ Identification of the steps that will be taken to help the toddler transition to the preschool setting (20 U.S.C., Chapter 33, Subchapter III, Sect. 1436 [d] [1–8]).

Documentation of Services from Age 3 to 21 Years

The IEP is the document that guides services for a child with disabilities between the ages of 3 and 21 years. The requirements for IEPs are described in Part B of IDEA. IEP services may include both **special education** and **related services**. For the purposes of the IEP, occupational therapy services are considered related services. As a related service provider, the occupational therapist would not serve as a service coordinator for children with IEPs but would contribute to the process of writing and revising the IEP. The IEP is written every year and reviewed every six months.

An IEP must contain the following elements:

◆ Present level of educational performance
◆ Annual goals
◆ Special education and related services
◆ Participation with nondisabled children
◆ Participation in statewide and districtwide tests
◆ Starting date and location of services
◆ Transition services (for children age 14 years and older transitioning to adult programs or work settings)
◆ Measurement of progress (20 U.S.C. Chapter 33, Subchapter III, Sect. 1414)

The fundamental difference between the IFSP and the IEP is that the IFSP is more holistic; it can address a broader range of needs (AOTA, 1999). An IEP must be educationally related. Each state or each school district within a state may establish its own forms for these docu-

ments; the federal regulations do not require use of specific forms. The federal regulations mandate the timetables for completing the documents and the content of the documents (Sames, 2005).

DOCUMENTATION IN EMERGING PRACTICE SETTINGS

Occupational therapy practitioners are now working in community-based programs such as homeless shelters, prisons, Welfare to Work programs, home hospice, and summer camps. In some cases, occupational therapy programs are new to these settings. The clinical approach to documentation might not be appropriate, especially if there is no medical record. If the occupational therapy practitioner is working with individuals in the new program, it is advisable to develop evaluation, intervention plan, progress, and discontinuation reports that are consistent with the AOTA documentation guidelines (2003) to the greatest extent possible. However, if the occupational therapy practitioners are providing services at a community or population level, they may simply provide the agency with periodic consultation reports with a less structured format.

Most consultation reports are narrative descriptions of the needs assessment, plan, implementation, and/or outcomes of the occupational therapy program.

Since occupational therapy practitioners in emerging practice settings are demonstrating the value of occupational therapy in new ways, they may use their documentation as a mechanism to demonstrate successful outcomes and benefits of occupational therapy services.

ADMINISTRATIVE DOCUMENTATION

Occupational therapists in any setting may have to write an incident report, a letter of appeal to a payer source, a grant proposal, or **policies** and **procedures**. These types of documentation are administrative because they are necessary for the ongoing administration of occupational therapy services. For example, to be paid for delivering occupational therapy services, occupational therapy providers may need to write letters to request funding or to respond to a denial of a payment. Policies and procedures must be written clearly so that all employees of the department understand and follow the departmental standards, ensuring that the

---

BOX 39.3   **WRITING FOR AN EVALUATION REPORT COMPARED TO A PRIOR AUTHORIZATION REQUEST LETTER**

Tatiana is a 16-month-old girl from a large Midwestern city. Three weeks ago, while under the care of her mother's boyfriend, she was allegedly shaken violently. Her mother brought her to the hospital two days later because the baby was sleepier than normal, did not seem to want to eat or drink, did not hold her head up, and did not engage in any play activities or smile at her mother.

Excerpt from Evaluation Report:

Tatiana did not focus on or visually track any objects in any direction. She did not reach for any toys that were quietly placed in front of her, but she did turn her head to localize sounds and flailed her hands in reaction to sound. Her fingers closed around a rattle placed in the palm of her hand. Passive range of motion was within normal limits in all extremities. Muscle tone was generally low. She rubbed her face or arm in response to light touch. When placed on her stomach, she rolled her head from side to side but did not lift her head. When placed in a sitting position, she was unable to hold her head up or maintain sitting unassisted. Tatiana made no attempts to roll over or bear weight on her arms. She is fed through an N-G tube; therefore chewing and swallowing were not evaluated at this time. She cried and made other noises but did not

form any words. Tatiana will need adaptive seating with head support and occupational therapy intervention to maximize her abilities to actively interact with people and her environment.

Excerpt from Prior Authorization Letter:

This 16-month-old girl was diagnosed with Shaken Baby Syndrome resulting in severe head trauma. She has low muscle tone and cannot assume or maintain a seated position unassisted. This child will need adaptive seating and positioning devices to ensure proper positioning of her trunk and limbs and to prevent deformities. Proper positioning is also important for her cognitive, social, and physical development. Her vision is severely limited; she is functionally blind. In a seated position, she will better be able to localize sound, use her arms and hands, and begin to engage in social interactions. Please refer to attached list of recommended adaptive positioning devices and their respective costs. In addition, I recommend occupational therapy intervention twice a week for three months (24 visits) to work on developing the movement, social, and cognitive skills needed to enable participation in daily life activities of typical toddlers. A list of measurable goals is included. . . .

department functions well. To effectively do their jobs, aides, who are high school graduates with some on-the-job training, as well as professional staff must understand policies and procedures.

Administrative documentation requires the use of terminology that anyone can understand; people who have limited understanding of occupational therapy jargon or medical terms may read these documents. Often, the first person who reads an appeal letter will be someone who is trained to interpret insurance company standards but who might not have a medical background.

Box 39.3 shows an example of a section of an evaluation report written for a medical record, and how it might be translated in a letter to an insurance company requesting authorization for services.

ELECTRONIC DOCUMENTATION

As more facilities move to electronic medical records, it is becoming more common to use a keyboard to enter data and comments than to pick up a pen and write on a form. Each electronic documentation system has its quirks, strengths, and weaknesses. Some systems are highly specialized for occupational therapy practitioners, which makes it more likely that all the required information will

TABLE 39.1 ADVANTAGES AND DISADVANTAGES OF ELECTRONIC DOCUMENTATION SYSTEMS

Advantages	Disadvantages
Legibility	Less flexibility in content
Speed (one click may enter a full sentence)	Investment in time and money
Automatic entry of client information	Learning curve required to develop proficiency in the system
Instant availability to anyone on the team	

Source: Sullivan (2001).

be included in the documentation. Others are more generic and might not have adequate space to add vital information. It is critical that the system be set up so that documentation will be in compliance with facility accreditation standards and payer requirements. Table 39.1 lists the pros and cons of electronic documentation systems.

ETHICAL DILEMMA

Documentation Standards

You work for a company that provides on-call occupational therapy personnel to hospitals and long-term care facilities in a large metropolitan area. You have been asked to work at a large long-term care facility that normally has a part-time occupational therapist and a full-time occupational therapy assistant. The occupational therapist went into labor early, and the temporary person who was hired to take her place during her maternity leave cannot start for at least three weeks. You have never worked in this facility before, but you have worked in other long-term care facilities and are familiar with the documentation requirements for Medicare and Medicaid.

On your first day there, you open the file for your patients and see that a few patients should have had 30-day intervention plans (renewals) written last week, but you can find no evidence that this was done. You ask the occupational therapy assistant whether the documentation could be somewhere else, and he says no. You find some progress notes on these patients, but they are irregular and inconsistent. Mostly, they just list some activities the patients worked on and say that the patients continue to progress toward their goals. Ten minutes later, you get a call from the medical records director saying that there are five patients for whom she cannot find a discontinuation summary and that the discontinuation summaries are needed for reimbursement. She asks you to write them, even though you have never seen the patients and the patients were discharged from the facility over a week ago. You know that the documentation must be done in order for the facility to get paid, but you feel uncomfortable documenting the care of patients you have never seen. The occupational therapy assistant says that he cannot help you because he is too busy with his own patients and he did not pay a lot of attention to the patients the occupational therapist was working with. What do you do?

PROVOCATIVE QUESTIONS

1. Can my documentation be used in a trial, even if I am not the one being sued?
2. If I am not a member of AOTA, do I have to follow AOTA standards for documentation?
3. What do I do if the electronic documentation system at my hospital does not offer a prewritten statement that accurately reflects my client's status?

Professional Presentations and Publications

KAREN JACOBS

> "The greatest problem in communication is the illusion that it has been accomplished. "
>
> —DANIEL W. DAVENPORT

Learning Objectives

After reading this chapter, you will be able to:

1. Describe the seven aspects to an effective professional presentation.
2. List four nonverbal factors in the delivery of a professional presentation
3. Describe the difference between a peer-reviewed and a non-peer-reviewed publication.
4. Describe aspects of an effective professional publication

PROFESSIONAL PRESENTATIONS

Occupational therapy practitioners frequently provide professional presentations to a variety of audiences. We have listened to professional presentations—some great, some that put us to sleep. Thinking back to professional presentations that you liked (or did not like), you could easily come up with lists of what to do and what not to do (Merchant 2005). Payne names seven factors that are important to an effective professional presentation: purpose, audience, speaker, message, language and delivery, audiovisual aids, and feedback (Payne, 2002, p. 142).

Purpose

The first step in the process of developing a professional presentation is to decide on its purpose. Why are you presenting? Is it to inform, instruct, define, demonstrate, or teach? For example, you might be asked to provide

a professional presentation at a weekly staff meeting during your Level II fieldwork on the effectiveness of assistive technology for clients who have low-vision impairments. The purpose in this situation might be to inform your colleagues of the most recent evidence-based research on the topic. Perhaps the purpose of your professional presentation is to persuade, influence, convince, or market a product or service. For instance, you might have the opportunity to provide a professional presentation on energy conservation strategies to a consumer group, such as the National Multiple Sclerosis Society. The purpose here might be to market occupational therapy services available at your workplace. Perhaps the purpose of your presentation might be to inspire or entertain your audience. One example of an inspirational professional presentation is the yearly presidential keynote address at the American Occupational Therapy Association (AOTA) national conference. Once you have decided on the purpose of your professional presentation, the next step is to conduct an audience analysis.

Audience

Who is your audience? Before preparing your professional presentation, it is important to analyze the background, demographics, interests, attitudes, and expectations of your audience. Having information about your audience, such as its preexisting knowledge, beliefs, and attitudes about your topic will help you better match your message and its delivery to the needs and expectations of the group (Payne, 2002). At the very least, determine the expected size of the audience. Presenting to a small group of colleagues at your Level II fieldwork site would be quite different from presenting to an audience of 50 to 100 occupational therapy practitioners at a state or national conference.

Speaker

Important, but sometimes overlooked, is how the audience's interest and potential knowledge gain from a presentation may be directly influenced by the speaker himself or herself. A speaker who has perceived expertise, such as career success (e.g., a Fellow of the American Occupational Therapy Association), work experience (e.g., 20 years of practice in the area of ergonomics), or job responsibility (e.g., Director of Rehabilitation Services); one who conveys trustworthiness, reliability, or sincerity; one with whom the audience has a degree of identification; or one who is charismatic has the right characteristics to make a professional presentation great (Payne, 2002) (Figure 40.1).

Message

The message of a presentation has three parts: the introduction, the body, and the conclusion.

FIGURE 40.1 A charismatic speaker inspires the audience with her enthusiasm and hand gestures.

Introduction

The introduction should always begin with a simple greeting, such as "good morning," or a thank you to the host (e.g., "Thank you, Dr. Jacobs, for inviting me to speak today"). One then continues with a brief preview of the presentation. A relevant joke, short story, or quote can also make an impressive starting statement. Whatever technique is used, it should arouse the audience's curiosity about your presentation and capture the audience's attention.

Body

The body of the presentation should contain at least 75% of your key points. The rule of three major points is always good to follow:

1. Preview your points.
2. Describe and substantiate them in a logical order.
3. Summarize your points (Payne, 2002, p. 145).

Use natural transitions between each point; transitions "form a bridge between parts of your presentation" (Milan, 2002, p. 2). Be sure to include references when invoking evidence-based research or supporting materials.

Conclusion

You have made it to the conclusion of your presentation. Now is your chance to tell the audience what you expect them to remember. Keep the conclusion brief, review salient points, and include a final statement that will leave a lasting impact. One could use a memorable quotation or reinforce a point from the story with which your introduction began. Always finish your presentation with a pause and then a "thank you," which gives the audience a sense of closure, and be sure to leave some extra time for

BOX 40.1 EXAMPLE OF AN OUTLINE FOR A PERSUASIVE SPEECH

Purpose

To persuade an audience that consists primarily of university graduate students of the importance of sitting properly at the computer, taking breaks, and using computer equipment.

Introduction

◆ Open with a greeting that refers to the group, such as "Good morning, Boston University graduate students. I am Dr. Karen Jacobs, a professor in occupational therapy at Sargent College."

◆ Introduce the topic by using a rhetorical question (e.g., "How many of you enjoy having aches and pains from using your computer?"), wait for a show of hands, and continue: "University students are spending more and more time sitting at a computer workstation to do homework, surf the Internet, and play video games. How you position yourselves in a chair, and how you use the computer equipment can affect not only your comfort, but also your health" (quote from AOTA).

◆ State that "Today I am here to talk to you about the importance of healthy computing and what you can do to stay healthy."

◆ Preview the points to be covered: (1) proper posture, (2) computer workstation arrangements, and (3) frequent stretch breaks.

Body

Begin with an attention-getting statement, and then focus on the three points with examples:

1. Proper posture: Encourage proper posture of the head, forearms, back, and feet: The head should be level with the monitor and the top of the screen at eye level. The forearms should be parallel to the keyboard and held only slightly above it. The lower back should be supported while sitting in front of a computer. Place a small pillow or rolled up towel between the back of the chair and the lower back to provide back support. The feet should rest flat on the floor or on a footstep.

2. Computer workstation arrangements: Arrange the computer desk and equipment so as to avoid glare from sunlight. Set the monitor 18 to 30 inches away from the person. Adjust the chair to an appropriate height for the person.

3. Frequent stretch breaks: Every 30 minutes, take a stretch break from the computer.

References to evidence-based literature are included.

Conclusion

◆ End the presentation by highlighting the responsibility each student has to his or her health.

◆ Briefly review the three points covered: proper posture, computer workstation arrangements, and frequent stretch breaks.

End with a quote or refer back to the rhetorical question in the introduction.

◆ Thank the audience for the opportunity to speak to them.

◆ Pass out your business cards so that interested listeners can contact you if they have any questions.

See also Payne, G. (2002). Oral presentations. In D. Nelson, R. Brownson, P. Remington, & C. Parvanta (Eds.),* Communicating public health information effectively: A guide for practitioners *(pp. 141–154). Washington, DC: American Public Health Association.*

responding to the audience's questions. Box 40.1 provides an example of an outline for a persuasive professional presentation.

Language and Delivery

Language

The language you use will depend on your audience analysis. If you are presenting to occupational therapy practi-

tioners, you want to make sure that the language you use conforms with the American Occupational Therapy Association's (AOTA) Framework. For an audience of people who are not occupational therapists, minimize the use of highly technical language or jargon. In general, use conventional words and phrases, use links and transitions, and try to use similes and metaphors to paint pictures in the minds of the audience. "The guiding principle is that language be suitable for the speaker, the subject, and the occasion." (Payne, 2002, p. 147).

BOX 40.2

RECOMMENDATIONS FOR THE DELIVERY OF PROFESSIONAL PRESENTATIONS

Verbal Factors

◆ Vary your voice pitch or melody; avoid speaking in a monotone.
◆ Pronounce and articulate your words and syllables.
◆ Speak slowly; an optimal range is 150–185 words per minute.
◆ Avoid filler sounds and words (e.g., "er," "uh," "you know," "okay").
◆ Project your voice; if your voice is soft, use a microphone.
◆ Use pauses or changes in your voice level to stress key points.
◆ Make sure your sentences are grammatically correct.
◆ Always stay within your allotted time.

Nonverbal Factors

◆ Dress conservatively, and avoid excessive jewelry; your appearance directly affects your credibility.
◆ Look at your audience.
◆ Make sure your facial expressions agree with your message.
◆ Interact with your visual aids, but do not read from them.
◆ Involve your audience; ask questions and wait for responses; call on individuals.
◆ Avoid clutching or leaning on the podium.
◆ Use gestures and movements appropriately.
◆ Avoid distracting mannerisms (e.g., drinking water, chewing gum, hands in pockets, twirling or clicking a pen).

Source: Adapted from Payne, G. (2002). Oral presentations. In D. Nelson, R. Brownson, P. Remington, & C. Parvanta (Eds.), Communicating public health information effectively: A guide for Practitioners (pp. 141–154). Washington, DC: American Public Health Association.

Delivery

Avoid using filler sounds and words, such as "er," "uh," "you know," and "okay" in the delivery of your presentation. These fillers are distracting and can reduce a speaker's credibility. "A speaker's delivery plays a vital role in enabling audiences to receive and respond to the message, and consists of both verbal and non-verbal aspects" (Payne, 2002, p. 147). Box 40.2 provides examples of recommendations for the delivery of professional presentations.

Now that you understand the need for effective language and delivery, practice, practice, practice your presentation! Rehearsing the presentation can help you to raise your confidence and sense of preparedness and develop a "can-do" attitude. Practice in front of friends and family, and ideally, videotape your presentation and review it to critically analyze your message, language, delivery, and use of audiovisual aids.

Audiovisual Aids

Audiovisual aids used in professional presentations include flip charts, posters, blackboards, overheads, slides, computer graphics, audio and video clips, and direct use of Internet sites. To be effective, audiovisual aids should help one to clarify, enhance, and support the message while holding the interest of one's audience (Payne, 2002). If you are using a visual aid, such as Microsoft Office PowerPoint®, apply the guidelines in Box 40.3.

BOX 40.3

GUIDELINES FOR SLIDES

◆ Slides should be an outline of the presentation.
◆ Use no more than six lines per slide, with six words to a line maximum.
◆ Font sizes should be 32 point minimum for titles.
◆ Font sizes should be 20 point minimum for text.
◆ Use no more than one slide per minute.
◆ Illustrate concepts with images or other visuals.
◆ Credit the author, date, title of article, and journal title on the slide in small print (18 point) at the bottom.
◆ References should be on the last slide in American Psychological Association (APA) format. Prepare backup materials, that is, print slides on overhead transparencies or bring handouts, just in case the computer or projector decides to be uncooperative.
◆ Rehearse and view visual aids ahead of time in the room where you will use them.
◆ Arrive at least 30 minutes before your presentation time, set up your audiovisuals. and stand in the back of the room to make sure they are visible.
◆ In a room with ambient light, it is best to use high-contrast colors; a dark background (e.g., blue) with light letters (e.g., yellow) is typically visually appealing.

ETHICAL DILEMMA

How Can an Occupational Therapy Student Meet Time Demands and Still Provide a Professional Evidence-Based Presentation?

Ariel, an occupational therapy graduate student, is anxious about presenting her first professional presentation at a local Parents-Teachers Association meeting. She has been invited to speak briefly on the importance of junior high school students' proper use of backpacks and has been instructed to limit her presentation to 10 minutes and 10 slides. She has so much information to put on the slides that she has decided not to include any citations or references on the slides. She will be providing her slides as handouts to the meeting's participants.

Questions

1. Does Ariel have an ethical responsibility to include citations or references on the slides?
2. What conflicts are present between not including citations or references on the slides and giving slides as a handout to the meeting's participants?

Feedback

You are now almost finished with your first professional presentation. Suppose you have noticed throughout that members of your audience have been nodding their heads as you speak, others have spontaneously laughed at your jokes, and still others are smiling when you make eye contact with them. This nonverbal feedback from your audience communicates that your presentation has been a success. Feedback is the final aspect of a professional presentation, and it is typically nonverbal. With experience, you can easily identify the nonverbal cues that audiences convey when a presentation is not a success: arched eyebrows, yawning, restlessness, talking, or even walking out of the presentation. It is your responsibility as a speaker to be constantly aware of your audience's nonverbal communication and to make necessary adjustments to your message or its delivery to better meet their needs and expectations.

PROFESSIONAL PUBLICATIONS

In the first part of this chapter, you learned about professional presentations. Now let us look at another important aspect of professional communication: professional publications. There are a variety of professional publications. Among them are books, journals, chapters in books, trade and magazine journals, newsletters, conference proceedings, and films or videos. There are also various media types. These include print, CD-ROM, audio, video, web, and software. In the hierarchy of professional publications are the following:

- Peer-reviewed journals
- Peer-reviewed conference proceedings
- Non-peer-reviewed books
- Non-peer-reviewed chapters in books
- Other non-peer reviewed materials

Peer-reviewed documents are those that are reviewed by "expert readers." Non-peer-reviewed documents typically have less demanding standards for screening prior to publication. Examples of these two kinds of publications include feature-length articles, briefs, reviews, case reports, letters to the editor, practice forums, and technical notes. The focus of the remainder of this chapter will be on peer-reviewed and non-peer-reviewed documents in occupational therapy.

Peer-Reviewed Journals

The peer review process is a form of assessment that is designed to provide constructive feedback to authors about their potential publication. Typically, submissions are evaluated by at least two reviewers, without their knowing the identity of the authors ("blind"). Reviewers are typically members of the journal's editorial board and are experts in their specific areas of practice. Depending on the scope of the journal, manuscripts are evaluated as to their relevance and contribution to the knowledge and practice of occupational therapy, aspects of methodology, statistical analyses, theoretical contributions, clarity, and style of writing. A typical review process is outlined in Box 40.4.

The most widely read peer-reviewed occupational therapy journal is the *American Journal of Occupational Therapy* (AJOT). It "is the official publication of the

<div style="border:2px solid #1a237e; padding:8px;">

BOX 40.4

TYPICAL MANUSCRIPT REVIEW PROCESS FOR PEER-REVIEWED JOURNALS

◆ **Submission of original manuscript and editor assignment (~1 week).**

A manuscript is submitted by its authors to the editor of the journal. The editor evaluates whether the manuscript is within the scope of the journal and whether it fulfills the journal's scientific and technical standards.

◆ **Manuscript is provided to peer reviewers for blind review (~4–8 weeks).**

Manuscripts, without any identification of authorship, are reviewed by at least two peer reviewers. Each journal has specific criteria for its review of a manuscript, but in general, the article is evaluated is on the basis of its contribution to the knowledge and practice of occupational therapy, methodology, statistical analyses, theoretical and empirical contributions, and clarity and style of writing. Typically, peer reviewers have four possible options for each manuscript:

1. Accept the manuscript without revision
2. Accept the manuscript after revision
3. Neither accept nor reject until the author(s) make revisions and resubmit the manuscript
4. Reject the manuscript

◆ **Editor reads peer reviews and compiles correspondence to the contact author (~1–3 weeks).**

The editor compiles the peer reviews and communicates the status of the manuscript to the contact author.

◆ **Publication of manuscript**

1. If the manuscript is accepted without revision, it is placed in the queue for publication. The manuscript is submitted to the publisher, who will send proofs of the manuscript to be reviewed by author(s) (~ **3–12 months,** depending on the journal's publication schedule).
2. If the manuscript is accepted after it is revised, the manuscript is placed in the queue for publication once the revision has been reviewed and accepted. The manuscript is submitted to the publisher, who will send proofs of the manuscript to be reviewed by author(s) (~ **5–14 months,** depending on the journal's publication schedule).
3. If the manuscript is neither accepted nor rejected, the resubmitted revised manuscript will be sent out for review; typically by the original peer reviewers.

</div>

American Occupational Therapy Association, Inc. and is published 6 times per year. This peer reviewed journal focuses on research, practice, and health care issues in the field of occupational therapy" (AOTA, 2007). "The journal publishes articles that are theoretical and conceptual and that represent theory-based research, research reviews and applied research related to innovative program approaches, educational activities and professional trends" (AOTA, 2007).

Another peer-reviewed occupational therapy journal is the *Occupational Therapy Journal of Research: Occupation, Participation, and Health* (OTJR). In contrast to AJOT, OTJR focuses on research articles and systematic review papers that advance the knowledge of occupation or focus on improving the lives of people who are at risk for restrictions to their participation in meaningful activities (American Occupational Therapy Foundation, 2007).

In the area of occupational science, the premier journal is *The Journal of Occupational Science* (JOS). The stated aim of this journal is to "give voice to the unique experiences, concerns and perspectives of the study of humans as occupational beings." It is "designed to provide opportunities to publish articles of interest to many

disciplines such as: anthropologists, ethnologists, ethologists, human geographers, philosophers, psychologists, occupational therapists, sociologists and social biologists" (Association of Occupational Science, 2007).

Box 40.5 contains a listing of the major international peer-reviewed journals with a primary focus on occupational therapy.

Non-Peer-Reviewed Documents

Some examples of non-peer-reviewed materials are books, chapters in books, trade journals, magazines, and newsletters. The best-known non-peer-reviewed magazines and newsletters in occupational therapy are *OT Practice,* the SIS *Quarterly* newsletters, and *1-Minute Update E-Newsletter,* published by AOTA, and *ADVANCE for Occupational Therapy Practitioners,* published by Merion Publications, Inc. These magazines and newsletters typically have less demanding screening standards before publication than do peer-reviewed journals but may include scholarly materials and newsy articles. Specifically, *OT Practice* "covers professional information in all aspects of occupational therapy practice today. Features include

---

everything from hands-on techniques to continuing education, legislative issues to career advice and job opportunities, to the latest professional news" (AOTA, 2007).

AOTA publishes 11 different SIS *Quarterly* newsletters, each of which focuses on a specific practice area, such as work, gerontology, school-based practice, or technology. These newsletters are published four times per year. The *1-Minute Update E-Newsletter* is a biweekly e-mail newsletter that features important news about occupational therapy, trends, ideas, and products. These publications are free to those with AOTA membership, or they may be purchased separately

ADVANCE for Occupational Therapy Practitioners is a biweekly news magazine that contains "stories on the newest treatment arenas, protocols and products, therapy equipment and modalities along with regular columns" (ADVANCE for Occupational Therapy Practitioners, 2005). There is no charge for subscriptions to *ADVANCE for Occupational Therapy Practitioners.*

CONCLUSION

As you finish this chapter on professional presentations and professional publications, think about setting these goals for yourself:

1. To follow the strategies described in the chapter for your next and all future professional presentations.

2. To keep up with the expanding body of knowledge in occupational therapy by reading at least three peer-reviewed articles a month.
3. To develop your skills to write articles/manuscripts for a professional publication.

Client Education

41

SUE BERGER

Learning Objectives

After reading this chapter, you will be able to:

1. Understand key factors that contribute to effective client communication
2. Understand the importance of health literacy throughout all types of client education
3. Choose and/or develop appropriate written client education materials

INTRODUCTION

As health care professionals, occupational therapy practitioners are educators. We teach our clients knowledge and skills they need to enhance well-being and live as safely as possible. Yet our own education focuses more on intervention skills and less on the strategies we need to be effective teachers. Chapter 36 provides the theoretical background related to learning; this chapter focuses on specific education strategies and how to effectively use them.

Rankin, Stallings, and London (2005) emphasize that client education is a partnership, involving both listening and sharing. Osborne (2001) identifies five key strategies to enhance communication in a client–health care professional partnership:

◆ Creating a positive environment
◆ Limiting the objectives of the communication
◆ Conveying the information clearly and slowly
◆ Using multiple strategies to communicate the message
◆ Verifying understanding

When possible, these five strategies should be used in all types of communication.

COMMUNICATING VERBALLY

We are constantly teaching our clients. We teach them how to perform one-handed dressing after they have had a stroke. Practitioners educate classroom teachers about appropriate environments to facilitate learning for students with special needs. We teach individuals about strategies for safely using community transportation. Often, the teaching occurs verbally. Whom one speaks with (characteristics of the client), how it is said (organization of the information), what is said (information included), and when it is said (environment and timing) all affect how the information is received, learned, and used.

Characteristics of the Client

As with all intervention, knowing the client and his or her strengths, limitations, culture, values, interests, age, and education level is fundamental. In communicating orally, knowing the client's literacy skills, native language, and auditory ability is also important. Though the definition of literacy refers to reading and writing, it also affects one's ability to comprehend oral information (American Medical Association [AMA], 1999). In communicating with someone with low literacy skills, it is helpful to be consistent with word choice. During a session on feeding skills, for example, the word *silverware* should be used throughout instead of alternating with *utensil.* Unusual or challenging words used in conversation should be defined, and acronyms should be explained (Centers for Disease Control and Prevention [CDC], 1999). Words such as *assessment* or *intervention* should be defined, or more common words should be used. Acronyms such as *ROM* and *ADL* should be used only after they are fully explained. If you are unsure of word choice, ask the client what word he or she uses to describe an item, and use that word consistently. For example, you might ask a girl or woman whether she refers to her top as her *shirt* or *blouse.*

Communicating with clients who are hard of hearing poses other challenges. It is helpful to choose an environment that is quiet and free of distractions, get the client's attention before speaking, and position oneself directly in front of the client (Osborne, 2001). Often, a client hears better from one side than the other, so it is important to take the time to find this out and position oneself on the stronger side. If the person wears hearing aids, make sure they are in place and working. If hearing is severely impaired, use other methods of communication along with, or instead of, speaking. When entering an environment in which there are distractions, ask the client whether you can move to another location, turn the television off, or find a better time that might be more beneficial for instruction.

Organization of the Information

Organization of information to be presented helps clients to understand and apply information. Though this is especially true for individuals with low literacy, all people, especially those who are in a new environment, are learning new information, are in pain, or are anxious, will benefit when material is presented clearly and in an organized manner. Therefore, plan the information to be conveyed before talking and speak in sequence (Osborne, 2001). For example, if you are working with a group of children to help them lighten their backpacks, begin by stating, "First decide what needs to go in; second, put heavy books at the back of the pack; and third, put lighter objects in the front of the pack."

Using demonstrations, models, and pictures along with oral communication also helps people to understand information (AMC Cancer Research Center, 1994). When teaching clients about the importance of eliminating clutter for safety, show before-and-after pictures of a kitchen and point out safety hazards and ways they were resolved. When teaching use of adaptive equipment, explain and demonstrate. Use multiple teaching methods, especially when working with groups of individuals, because different people learn differently. Even when working with one client, multiple teaching methods help to emphasize key information and facilitate comprehension and memory.

Finally, one must verify understanding. The practitioner might believe that he or she was clear, organized, and consistent, but if the client did not understand the message, the practitioner was not successful. There are many ways to verify understanding, including asking the client to demonstrate, to repeat in his or her own words, or to explain a concept using a different example (Doak, Doak, & Root, 1996). The individual who is passive or constantly nodding in agreement might not fully understand or adhere to the recommendations. Therefore, it is helpful to encourage questions, input, and ideas, all of which lead toward involvement and more potential for follow-through (DiMatteo, 1995). When possible, ask one client to demonstrate or to teach other clients. Clients are more likely to ask questions and admit lack of understanding with a peer than with a therapist.

Information Included

Several studies have found large discrepancies between what clients wanted to know and what health professionals believed was most important. Davis, Fredrickson and colleagues (1998) found that low-income, low-literacy, minority women were most interested in learning about cost of procedures, something that was rarely addressed. Reid and colleagues (1995) learned that many people wanted information about treatment and prognosis, yet this was often not addressed. To facilitate comprehension and recall, it is important to understand what information the client wants and needs to know and to communicate this information clearly (AMA, 1999).

Recall of information depends on two factors: the type of information and how the information is presented. Bradshaw, Ley, and Kincey (1975) studied participants' recall about how to develop healthy eating habits. The participants remembered information when it was perceived as important. Also, information that was given as specific suggestions was recalled more often than general suggestions were. For example, "Walk briskly for 30 minutes three times a week" would be recalled more often than "Exercise several times a week."

Cultural sensitivity is a critical factor for effective client education. Terminology, topics, and ideas should all be relevant to the intended audience. When possible, communication should be in the person's native language. Professional interpreters are best to prevent miscommunication

and ensure privacy (Rankin et al., 2005). However, this is not always possible, and family members might be the only available interpreters. Caution should be used in this situation, as family members' own opinions and reactions are often conveyed as well or instead of the client's (CDC, 1999). The best interpreters are those who have been trained to interpret, not just someone who speaks the same language.

Being culturally sensitive involves more than speaking in the client's native language. One should use culturally relevant examples, consider the meaning of personal space and time within the client's culture, and be careful about making judgments or interpretations without checking this out with the person (Purtilo & Haddad, 2002). Being cognizant of cultural differences and beliefs in health and wellness is the first step toward effective communication with individuals of cultures other than one's own. See Huff, and Kline (1999), Rankin and colleagues (2005), or World Education (2000) for more in depth information on culturally competent client education.

Environment and Timing

The environment in which client education occurs can influence comprehension and recall. It is important for information to be shared in a shame-free environment (Osborne, 2005), a setting in which the client feels free to ask questions, admit lack of understanding, or ask for repetition. Internal distractions such as pain, anxiety, hunger, or need to use the bathroom also affect one's ability to absorb and understand information. And because some people are "morning people" and others are more alert (and receptive to information) in the evening, timing of all client education is important.

When working in schools, schedule evening hours to provide parent education. Parents who need to take time off from work to attend a meeting may arrive frustrated and angry and will be less open to hearing new information.

COMMUNICATING IN WRITING

Kessels (2003) showed that most people forget up to 80% of what they are told during a patient-physician interaction and that almost half of what they believe they remember, they remember incorrectly. Reinforcing oral communication with print material can help recall and comprehension. Written forms of communication reinforce what is said, provide a record of what is said, and provide reminders of what is conveyed. If it is worth the time to write down information, it is important to ensure that the reader can use the material.

The main considerations for effective written communication include the characteristics of the user of the material; the information the therapist wants to covey or, more important, the information the client needs and wants to know; the **reading level** of the material; the presentation of the material; and the cultural relevance of the material (Butow, Brindle, McConnell, Boakes, & Tattersall, 1998; National Cancer Institute, 2003).

Characteristics of the Client

In all occupational therapy practice, it is important for the practitioner to know the client and his or her strengths, limitations, culture, values, interests, age, and education level. For written communication, knowing someone's general reading ability is also important. Reading levels may be impaired for individuals with disabilities, those who are reading material that is not in their native language, and, of course, those who never learned to read. When giving any written material to a client, one should note whether the client states something similar to "I'll read this later so I can discuss it with my husband," "I left my glasses at home," or "I'll remember what you say—no need to write it down." Does the client appear to read something but then is unable to follow the instructions? Good observation skills can provide a great deal of information about reading level. Knowing that a client struggles with reading will guide a practitioner to use some of the strategies discussed below. Though there are standardized reading level assessments, more research is needed to determine whether formally assessing a client for reading level affects practitioner-client relationship or improves outcomes (AMA, 1999). Reading literacy also does not imply reading comprehension.

Just asking, "Do you read much?" can guide intervention. If the answer is no, that can be a cue to use strategies other than written materials to reinforce information.

Information Included

As with oral communication, it is important to focus on material that the client wants or needs to know when developing or choosing print materials. Though something that is "nice to know" might seem valuable to include, more is often not better (CDC, 1999; Osborne, 2001). In considering what material to include in written pamphlets, brochures, or home programs, prioritize the information and focus on a few key, relevant objectives. Remember to prioritize information by what is important to the client, not what you believe is important for the client to know.

Reading Level of the Material

Much public information, such as newspapers, is written at the tenth-grade level or higher. However, the 2003 National Adult Literacy Survey (NALS) found that approximately one out of three Americans is functionally illiterate, defined as reading below the fifth-grade level, and this number increases to one in two people who struggle with

reading when those with only marginally better reading skills are included (Kutner, Greenberg, Jin, & Paulsen, 2006). Though about 20% of these people either have learning disabilities or were born outside the United States, the majority of those who cannot read are white, native-born Americans (AMA, 1999). Butow and colleagues (1998) looked at preferences for brochures about cancer. Participants showed a clear preference for the brochure that was written at an eighth-grade level as compared to those at the eleventh-grade level. In a large randomized controlled study about polio immunization information, Davis, Fredrickson, and colleagues (1998) found that comprehension increased with written material at a fourth- to sixth-grade level for all individuals. The study also showed that the simpler form did not insult those with higher education and higher income. Use of a low reading level in written materials meets the needs of a large number of people.

Though there are numerous assessments to determine the reading level of written material, in general using short sentences and one- or two-syllable words is a simple strategy that will keep the reading level low (AMC Cancer Research Center, 1994). Though it is often impossible, and sometimes not desirable, to eliminate all words of three or more syllables, it is a good idea to use a simpler, common word when feasible. Using the word *doctor* instead of *physician* or using the term *thinking skills* instead of *cognition* is sometimes appropriate. One must be careful when using this strategy, however. Short, choppy sentences are not always easier to read, and some three-syllable words that are commonly used in conversation can facilitate readability (Reid et al., 1995). Shorter sentences and use of primarily one- or two-syllable words should be used as a guideline only. If the reader wants to learn more about standardized readability formulas or computer generated formulas, the book by Doak and colleagues (1996) or the help feature in Microsoft Word 2007 are recommended.

In addition to reading level, other factors influence the readability of printed material. For example, the use of all capital letters is more challenging to read than is a combination of uppercase and lowercase letters, because readers use the shapes of words to help read. For example, when typed in all capitals, "AND" looks like a rectangle and is visually very similar to "FOR," "THE," or any other three-letter word. If typed with lowercase letters, "and," "for," and "the" all have different shapes, and it is therefore easier to quickly determine the word (Doak et al., 1996). Box 41.1 provides examples of easy and difficult to use layouts and fonts.

The use of common words makes reading easier as well (CDC, 1999; Executive Secretariat, 2003; Osborne, 2005). Most people understand the term *high blood pressure* better than they do *hypertension.* If it is important to use the term *hypertension,* it is suggested to define it and use it consistently. Use of descriptions that are simple to

---

BOX 41.1

EXAMPLES OF FONTS AND LAYOUT THAT ARE EASY VERSUS DIFFICULT TO READ

1. It is easier to read material that is written using a combination of uppercase and lowercase letters THAN MATERIAL WRITTEN IN ALL CAPITALS.
2. It is easier to read print in Times New Roman, a font with serifs, than to read material printed in Arial, a sans serif font.
3. It is easier to read material that uses a 12-point font than material that uses a 9-point font.
4. It is easier to read the material written above that is single-spaced than what you are reading right now, which is less than single space. Remember that spacing and allowing for white space are important.

---

visualize is another helpful strategy. In encouraging someone to lift only small items, the commonly used expression "no bigger than a bread box" is easier to understand than "no bigger than 2 feet by 1 foot by 1 foot."

To make written information readable, use active rather than passive wording and use positive terminology (CDC, 1999; Executive Secretariat, 2003; Osborne, 2001). For example, write, "Put your right arm in first when getting dressed" instead of "Your right arm should be put in first when getting dressed," and state, "Raise your arm slowly" instead of "Do not raise your arm quickly." Use acronyms, such as ADL or ROM, only after they have been clearly explained; even then, be sure to verify comprehension.

Presentation of the Material

The overall presentation of any written communication is important. Presentation includes, but is not limited to, the type of paper used, the color of paper and print, font size and style, visuals, and organization. These factors affect one's ability to see the material, read the material, and understand the material and one's motivation to read the material.

Font and Paper

To ensure that the majority of people can see the written material, it should be typed in a font with serifs (the small lines at the end of characters) and a font size between 12 and 14 points (CDC, 1999) or a font size of 14 points or greater for readers with low vision (Osborne, 2001) (see Box 41.2). The CDC (1999) also recommends limiting the use of fancy fonts or italics. In general, the same font style should be used throughout a document.

EXAMPLES OF DIFFICULT-TO-READ VERSUS EASY-TO-READ FORMATS

Difficult to Read

Bedroom
–Put a light on the bed table
–Keep a telephone next to the bed
Bathroom
–Keep a nightlight on at night
–Put nonskid decals in the tub

Easy to Read

◆ **Bedroom**
–Put a light on the bed table
–Keep a telephone next to the bed

◆ **Bathroom**
–Keep a nightlight on at night
–Put nonskid decals in the tub

Matte paper should be used, as glossy paper can cause glare and make reading difficult. Black print on white paper is often most effective for contrast (Osborne, 2001). However, if color is desired, it is important to use opposing colors from the color wheel. For example, if yellow paper is to be used, the font should be blue (opposite yellow) rather than orange (next to yellow). Finally, to ensure that the written material can be seen, the reader should read it in an area with adequate lighting.

Organization

The organization of the material affects readability. Highlighting key information by making it bold or underlining it adds focus to important information. Headings are helpful to group information. Including white space, rather than filling up all the paper with words and pictures, facilitates self-efficacy (Osborne, 2001). Looking at a brochure that is unappealing and crammed with information will be discouraging for clients, regardless of the information in the brochure. Include key information first or last, as readers remember this information best (CDC, 1999; National Cancer Institute, 2003).

Spacing is important for visual cues. Leave more space above headings and subheadings than below. This ties information together at a quick visual glance. Consider using simple questions as headers, such as "What is energy conservation?" and "What are the key principles of energy conservation?" Chunking information into five or fewer categories facilitates recall. Information can be divided by rooms in a house (for a handout on environmental adaptations), by principles (for a handout on energy conservation), or according to any categorization that is appropriate for the topic. Box 41.2 provides examples of formatting that are easy and difficult to use.

When possible, the material should be personalized. This can be done simply by writing the user's name at the top of the material or by leaving blank space for individualizing exercises or adding suggestions. Using terminology such as "your exercise program" rather than "the exercise program" has been shown to make a difference in both

recall and satisfaction with the material (Wagner, Davis, & Handelsman, 1998).

Visuals

The old saying "A picture is worth a thousand words" is true only if the picture is clear and appropriate. Several studies have shown that written materials that used both text and visuals were better received than were materials with text alone (Bernardini, Ambrogi, Rardella, Perioli, & Grandolini, 2001; Davis, Bocchini, et al., 1996; Michielutte, Bahnson, Dignan, & Schroeder, 1992). Health literacy literature emphasizes the importance of visuals that are culturally appropriate, simple to understand, and used with simple captions (CDC, 1999; National Cancer Institute, 2003). Use shapes with simple words that are often universally recognized. For example, use a picture of a stop sign to reinforce the importance of stopping activity before pain occurs. Visuals, like words, should convey the positive. For example, include pictures of healthy foods rather than a picture of chips and cookies with a line through it. Some visuals can be confusing rather than helpful. For example, pictures with many arrows or bus schedules with small font and many columns are difficult to use. The purpose of using visuals is to facilitate comprehension. Pictures as decorations can detract from the message. All pictures that are included should convey an idea, enhancing the message in the text (AMC Cancer Research Center, 1994; CDC, 1999).

Cultural Relevance

It is important to be culturally sensitive in all written material, both words and visuals. Terminology, topics, and ideas should be relevant to the intended audience. The most effective way to ensure cultural relevance is to get input from the intended user (CDC, 1999) both in the development of the material and for feedback and suggestions once the material is in final draft form and during revisions. As with oral communication, print material, whenever possible, should be available in the client's

native language, with particular emphasis on the use of culturally relevant terminology. Though there are Web-sites and computer programs that translate material, they translate word for word and are not as effective as having a person translate.

Assessing Print Material

Table 41.1 provides a quick checklist to consider in developing or choosing print material to use with clients. There are several published assessments to use to ensure that

TABLE 41.1   GUIDELINE TO CONSIDER WHEN DEVELOPING OR CHOOSING PRINTED MATERIALS

Characteristics of the user
1. Was the age of the user considered?
2. Was the education and/or reading level of the user considered?
3. Were the values, beliefs, and interests of the user considered?

Information included
1. Is the information what the user might want to know?
2. Is the information what the user might need to know?
3. Is only key information included?

Reading level of the material
1. Are there a limited number of long and/or compound sentences?
2. Are the majority of words that are three or more syllables common, everyday words?
3. Are unusual words defined? When possible, are common words used?
4. Is the same term used consistently?
5. Are common descriptions used to assist with visualization?
6. Is active terminology used?
7. Is terminology phrased in the positive?

Presentation of the material
1. Is a font style with serif used?
2. Is the font size at least 12 points (greater for people with low vision)?
3. Is there a strong contrast between color of print and color of paper?
4. Is matte paper used?
5. Is bold or underlining used for emphasis?
6. Are headings and subheadings used to chunk information and for layout?
7. Is adequate white space used?
8. Is key information included first or last?
9. Is information personalized?

Visuals
1. Are visuals culturally appropriate?
2. Are simple captions included for each visual?
3. Are visuals conveyed in the positive?
4. Do the visuals convey information (not just for decoration)?
5. Are the visuals clearly sequenced?

Cultural relevance
1. Is the material relevant to the intended audience?
2. Is the terminology culturally appropriate?
4. Was the material reviewed with the intended audience prior to distribution?
5. Is the material available in the user's native language?

written materials are developed well. The Suitability Assessment of Materials is commonly used and was developed and validated by Doak and colleagues (1996). It takes approximately 30 minutes, and the result is a numerical score, with a higher score indicating better suitability of the material for a given audience. The best way to assess printed material is to ask potential users for feedback.

COMMUNICATING WITH MEDIA

Audio, video, and **multimedia** communications are other strategies that can be used to communicate information to clients. These modes of communication can be effective if developed well. Individuals with low literacy skills may benefit from listening to and viewing information if it is developed in a fun, interactive, and appropriate way. However, videos are not a panacea for those with low literacy skills. While possibly having average or above-average intelligence, individuals who struggle to read often process information differently and might have limited vocabulary and a limited attention span (Doak et al., 1996). Everyone has a different learning style. Some learn best by reading, others by listening, and others by seeing. For many, learning information in multiple forms reinforces the information and assists with recall.

In choosing or developing audio or video materials, similar considerations should be used as for written materials. For instance, limiting objectives is important for all client education., The message should be five minutes or less for audio and eight minutes or less for video unless breaks are incorporated (Doak et al., 1996). While for printed material, information included at the beginning and the end of the material is most often remembered, with audio and video, the information presented at the end is recalled most often (Doak et al., 1996). For audio, when possible, use voices of people like the intended audience, and for video, be sure that images are of people like the intended audience. Whenever possible, these tools should be used in an interactive format.

Multimedia is still new technology, and research on its use is limited, though there is some evidence to support it. Computer games and software that require touch screen interaction (with the response generating the next question) are often fun, motivating and effective in conveying information (AMC Cancer Research Center, 1994; Rankin et al., 2005).

Video, audio, and multimedia are effective methods of communication, but they are more expensive to produce and more time consuming to develop than are written materials (AMC Cancer Research Center, 1994). Though there are numerous ways, as discussed earlier, to make written material user-friendly and increase readability, many people cannot understand print materials alone no matter how well developed they are (Atkinson, 2003). For the client who struggles to read, the use of video, audio, or multimedia might be worth the expense and time (Rankin et al., 2005).

CONCLUSION

Numerous studies have shown that no one method of client education is effective for all individuals (Friedrich, Cermak, and Maderbacher, 1996; Moore et al., 2002). Some material and learning are better suited for certain methods of teaching, and some individuals learn best via certain teaching strategies. "One size fits all" is not an effective motto for client education. Though more research is needed to determine the best ways to provide

---

PRACTICE DILEMMA

COMMUNICATING WITH CLIENTS

You work in an outpatient clinic with an 85-year-old client who comes twice a week to therapy secondary to a stroke three weeks ago. He has aphasia and struggles to read, though he can read single words. He understands most of what is being said. He achieved a sixth-grade education. His goal is to be able to do his own self-care, as his wife's emphysema is getting worse and she needs to cut down on the assistance she provides for him. Currently, he is working on one-handed dressing. Though he can don his sweater in the clinic with visual and verbal cues, you want to send home instructions for reminders so that he can practice in between sessions, when dressing at home.

1. What are some strategies to use to make this handout user-friendly for this client?
2. Develop a one-page handout focusing on donning a shirt.
3. Are there other strategies you could use besides print material to reinforce at home what is learned in the clinic?

client education, considering multiple modes of communication and the specific needs of the individual or groups of individuals will help to convey valuable information to clients.

PROVOCATIVE QUESTION

What are some of the many ways in which low literacy skills affect clients' abilities to participate in meaningful occupations?

VIII

CONCEPTUAL BASIS FOR PRACTICE

> "A theory is a good theory if it satisfies two requirements: it must accurately describe a large class of observations on the basis of a model that contains only a few arbitrary elements, and it must make definite predictions about the results of a future observation."

Theory and Practice in Occupational Therapy

ELIZABETH BLESEDELL CREPEAU,
BARBARA A. BOYT SCHELL,
AND ELLEN S. COHN

Learning Objectives

After reading this chapter, you will be able to:

1. Discuss the importance of theory in shaping knowledge in the field.
2. Describe the relationship between theory and practice.
3. Discuss how assumptions, personal theory and more formal theory. shapes the clinical reasoning of occupational therapy practitioners.
4. Discuss how to evaluate theory and why this is important.

Becoming an occupational therapy practitioner involves learning the knowledge, skills, and values of the field. An important part of this process is the ability to understand and use theoretical knowledge (Parham, 1987). Theoretical knowledge or ideas, when combined with the practitioners' personal and professional experiences, form the basis for professional action. As described in Chapter 32, the combination of all these factors results in the development of individual professional paradigms or mental models that practitioners use to guide their actions (see also Cervero, 1988; Griswold, 1995; Hooper, 1997, 2007, Törnebohm, 1991). An individual's professional paradigm involves an integration of the following elements:

- The practitioner's underlying beliefs, values and commitments
- The practitioner's occupational therapy knowledge, abilities, and skills including theories, evaluation, and intervention strategies
- The practitioner's professional values as expressed in a commitment to the field and to people who seek his or her care.

Practitioners draw on their professional paradigms as they work to enhance their clients' abilities to engage in valued occupations. Through experience, professional paradigms become more highly developed and provide a greater

resource for practitioners to reflect about their practice and the problems encountered by their clients (Griswold, 1995; Schön, 1983; Törnebohm, 1991). Refer to Chapter 32 to learn more about these clinical reasoning processes and how they are developed. Of particular interest for this current section is to explore theoretical knowledge and why it is important for effective occupational therapy practice.

WHY IS THEORY IMPORTANT?

The inability of experienced practitioners to explain their actions based on underlying assumptions and theories is one of the most perplexing issues for occupational therapy students as they enter the field. Such experiences can lead students to wonder why learning theory is important if practitioners aren't even using it in their daily work with their clients. In fact, practitioners do "use" theory all the time, they just can't always easily identify all the theories which inform their practice. This chapter explains how practitioners use theory and why theory is important.

Theory Shapes Profession's Practices

Theory is important because it is part the knowledge base of the field and an important aspect of each practitioner's professional paradigm (Argyris & Schön, 1974). However, practitioners do not necessarily retain the sources of the knowledge that form their professional paradigm. For instance, practitioners are generally very ethical in their practice, but few would be able to list all the specific terms associated with their ethical knowledge. With increased experience, practitioners tend to integrate knowledge in such a way that it becomes automatic (Argyris & Schön, 1974; Schön, 1983, 1987). Think about how little experienced drivers pay attention to the mechanics of operating a car. In the same way, practitioners become more automatic in their use of theoretical knowledge and just "do therapy." So, although theoretical knowledge may be embedded in the professional paradigm, it is part of the data practitioners bring to the therapeutic encounter (Rogers, 1983, 1986). It helps practitioners to "name and frame" the problems they encounter (Parham, 1987, Schön, 1983, 1987).

Use of Theories Varies with Experience

Theory may be particularly important for new practitioners who have little experience to draw upon. It can be seen as borrowed experience, a thinking frame (Neistadt, 1998), or metaphor (Parham, 1987) to assist new practitioners in their professional reasoning. For experienced practitioners, theory helps their reflective processes as they work to articulate reasons for their actions, and evaluate the effectiveness of these actions against existing theory and the responses of their clients. The current emphasis on evidence-based practice in health care is an attempt to have all practitioners be more systematic in understanding the sources and validity of knowledge they use in practice. In order for practice to improve, it is practitioners' ethical responsibility to routinely and systematically check their professional paradigms against emerging theory and research.

WHAT IS THEORY?

In the broadest sense, a theory is a set of ideas or concepts that people use to guide their actions (Morse, 1997). A theory reflects an image or explanation of why or how a phenomenon occurs. When fully developed a theory defines concepts and states relationships between them (Morse, 1997) giving people the tools to understand, explain, or predict phenomenon (McColl et al., 2003). Theory in occupational therapy concerns occupation, how occupation influences health and well-being, and how occupation can be used therapeutically to enable people to engage in those occupations they value most. Types of theories range from **personal theories**, which are private understandings about the issue of concern, to **formal theories**, which are publicly articulated, published, and validated to varying degrees by scientific study. For example, one occupational therapy student indicated that she had learned to suspect a violent or abusive cause whenever a woman came to the clinic with tendon and nerve injuries from lacerations to the palms of her hands. She had noticed, while working as an aide, that such women described using their hands to protect their faces when attacked by abusers with knives, and hence, would get knife wounds on the palms of their hands. This would be an example of a personal theory, because this student had never really even talked about her observations, much less researched or published her impressions. However, her personal theory did serve to guide her thinking to some degree. Alternately, another student might find that she was able to use information from both cognitive and occupational behavior theories to understand why a client in the nursing home did not seem motivated to dress herself or take her medications. In this case, the student would be using one or more formal theories to support her professional reasoning.

Scope of Theories

Formal theory can be considered in terms of the breadth or scope of the theory as it relates to professional practice. For instance, there are theories that address occupation from a broad perspective. These theories include theories from occupational science about the nature of humans as occupational beings, which shape how members of the profession view human activity. Information from occupational science and related disciplines formed the basis for chapters in Unit I. Occupational theories tend to be overarching theories which are broad in scope and help translate our understanding of the occupational nature of humans (McColl, et al., 2003). The remaining chapters in this unit

CASE STUDY: *Thinking Behind the Therapy: George Shows Mrs. Rivera a Bathtub Transfer*

Look at this picture of Mrs. Rivera, a fully clothed older woman of Hispanic descent, sitting on a shower seat in a bathtub holding a hand-held showerhead. Outsiders to the health care field might have difficulty making sense of this picture. Why would a fully dressed, well-groomed, dignified older woman be sitting on a shower stool holding the shower over her head in a completely dry (thankfully!) bathtub? The answer for us is obvious; she is receiving occupational therapy following a mild cerebrovascular accident. George, the occupational therapy practitioner, acted on his own assumptions and theoretical perspectives to use a "practice" shower such as this rather than having Mrs. Rivera actually take a shower in her current living environment.

What Do You See?

What assumptions guided George, Mrs. Rivera's OT practitioner, to have her "take" a shower in this way? Based on what you see in the picture, can you articulate the assumptions the practitioner might have made about

- Autonomy, independence, interdependence?
- The importance of daily hygiene?
- Transfer of learning?
- Motivation?
- Cultural values?
- Occupation-based practice?
- Therapeutic change?

What Theories Might Have Shaped George's Thinking?

What theories might have shaped George's thinking? Probably there are some overarching theories about the importance of engaging in occupation that provide general guidance to the therapy process. An example in this

case is the Model of Human Occupation or the Person-Environment-Occupation model, which direct the therapist to attend to Mrs. Rivera's desire to perform her self-care activities at home. The Theory of Occupational Adaptation might provide insight as to the ways Mrs. Rivera responds, as well as her own evaluation how satisfactory this approach to bathing is likely to be. There are also likely some other theories obtained from other professions, such as education and psychology, which form the basis for assumptions about how people learn, and the best way to teach them. One can presume from this picture that the therapist believes that this experience in the clinic learning to use a bath bench will enable Mrs. Rivera to use one at home to bathe more safely. Other theories, both within and outside of occupational therapy help inform the practitioner about more focused aspects of the therapy process. For instance, biomechanical theories and principles drawn from kinesiological theories would help the practitioner safely help Mrs. Rivera to position herself as she transfers in and out of the tub. The mechanisms of change are embedded in all of these theories

Theoretical Approaches and Mechanisms of Change

George, the occupational therapy practitioner, was probably using several theoretical perspectives when he asked Mrs. Rivera to "take a shower." Even though they may not be able to readily articulate their theoretical perspective (see Chapter 32 for an explanation of professional and clinical reasoning) practitioners should understand the mechanisms of change embedded in the theoretical perspectives they have adopted so that the intervention strategies are aligned with this perspective.

- What caused Mrs. Rivera's problem?
- Select a theory or theories that would be appropriate for this problem.
- Based on your theoretical perspective(s) what do you expect to change and why?
- Where do the ideas about change come from?
- What does the theory or model suggest will bring about change?
- Is there evidence to support the theory's assumptions about change?

After you have read through the theories in this unit, as well as learned more about the many theories informing practice, you may want to revisit this case to see the many theories which may inform a simple OT intervention like teaching someone a tub transfer.

address these overarching theories. Narrowly focused theories tend to focus on more specific aspects of occupational therapy evaluation and intervention. For example, biomechanical theory is concerned with the mechanics of body movement, such as joint mobility and posture, while motor control theories speak to the neuromuscular processes involved in performing skilled movements necessary in responding to daily life demands. Theories concerned with cognitive skills such as executive functions and problem solving provide guidance for practitioners working with individuals with brain injury and persistent mental illnesses. Such theories may include tested strategies to help individuals to improve their capacity to plan and sequence their daily tasks and activities. These more focused theories are discussed in the chapters in Units XI and XII, which address evaluation and intervention for personal factors and the environment. Practitioners have access to an increasing number of formal theories that they can use to guide their practice. Refer to Table 42.1 for examples of both broad and focused theories used in occupational therapy.

TABLE 42.1   DEFINITIONS OF COMMONLY USED TERMS

Term	Definition	Function	Examples
Paradigm	A paradigm provides a conceptual structure for understanding the world. A professional paradigm provides an accepted orienting structure for the profession, its values, beliefs, and knowledge.	Supports field's identity by providing common focus	Through engagement in occupations, people find meaning, health, and well being.
Professional Model	A professional model delineates and defines the scope or area of concern for a profession. It articulates the overall beliefs and knowledge of the profession. A professional model is derived from the profession's paradigm.	Defines the scope of practice.	Canadian Model of Occupational Performance
Theory	A general term that describes an image or provides an explanation of why or how a phenomenon occurs and how that phenomenon can be controlled	Organizes observations and understandings for easier use	See below for both formal and informal examples
Formal Theory	Explains observable events or relationships by stating a series of abstract propositions or principles. These theories are based on systematic research with carefully defined concepts and explanations of relationships between these concepts.	Systematically explains predicts, or describes phenomena	◆ Model of Human Occupation ◆ Ecology of Human Performance ◆ Occupational Adaptation ◆ Person Environment Occupation Model
Personal Theory	Private understandings based on experience	Helps individuals articulate their experience.	◆ A practitioner's theory that her female client's hand wounds were the result of protecting themselves from physical abuse.
Frame of Reference	Frames of reference guide practice by delineating the beliefs, assumptions, definitions, and concepts within a specific area of practice. A frame of reference is drawn from a theoretical base and has a particular view of the function/dysfunction continuum. A frame of reference delineates evaluation processes and intervention strategies that are consistent with the theoretical base.	Guide a specific area of practice	◆ Motor control ◆ Self-Advocacy ◆ Rehabilitation ◆ AOTA Practice Guidelines

(Kielhofner, 1997; McColl et al., 2003; Morse, 1997; Mosey, 1992; Turner, 1986)

Terms Used for Different Levels of Theory

Readers may also come across other terms related to theories, such as practice models, or frames of reference. Generally such terms are used to describe the level of development or complexity of a theory or as a way of differentiating practice guidelines from more formal theory (Mosey, 1992). Although helpful for scholars, for purposes of this chapter, these distinctions are less important. Examples of these terms are found in Table 42.1. More critical for new practitioners is the ability to understand the differing purposes or scopes of major theories used in the profession, their components, and how well these theories have been validated by research and found useful in practice.

SCOPE OF PRACTICE AND THE PROFESSION'S THEORIES

Broadly accepted professional knowledge about occupational therapy is often articulated in major documents approved and published by professional organizations, such as the American Occupational Therapy Association or the Canadian Occupational Therapy Association. The Canadian Model of Occupational Performance (Townsend, 1997) serves as a general guide to the profession and defines its scope of practice and the expertise and knowledge of occupational therapy practice. It provides a framework that delimits the profession's range of interest and focuses attention to those aspects of human functioning that are of greatest concern to occupational therapy practitioners (Moyers, 1999). Such documents often attempt to distill the assumptions, knowledge, values and beliefs commonly accepted throughout the profession (Mosey, 1981) and evolve to reflect the changing nature of professional practice. The knowledge base is derived from research and theories in occupational therapy, occupational science, and disciplines beyond the field.

Although such documents are useful in helping to frame the general concerns of the profession, and as such serve as good starting points for students, they rarely reflect the detailed information provided in various formal theories. Formal theories explain observable events or relationships by stating a series of abstract propositions or principles. These theories are based on systematic research with carefully defined concepts and explanations of relationships between these concepts (Turner, 1986). Formal theories are publicly shared through presentations at professional meetings, and publications in research journals or texts. This public sharing promotes critical analysis of theoretical assumptions, which in turn serves to gradually refine theories in response to continued analysis and research. For example, the Model of Human Occupation is a broad theory of occupational behavior that has evolved over nearly thirty years and been continually revised in response to criticisms from the field, research directed to testing aspects of the theory, and evolving theories from fields outside of occupational therapy (see Chapter 44 for a discussion of some of this evolution). Similarly, theories of about sensory processing, cognition, etc. (see Chapters 57 and 58) have been developed, revised, and improved through the scholarly process. Other theories are newer to the field, and thus have had less time to develop such as the Theory of Occupational Adaptation. Finally, there are some theories that have not been researched significantly since they were introduced into the field. This leads to the importance for practitioners to stay abreast of knowledge development in the field.

RELATIONSHIP BETWEEN THEORY AND PRACTICE

Theories, whether they are formal, informal, personal, process, or content, can help practitioners reason about what to observe, how to understand the occupational problems faced by clients, and how to intervene to address particular kinds of problems in practice. By explaining factors that affect a person's occupational performance, many theories provide practitioners with a map for thinking about the mechanism of change. The term *mechanism of change* refers to how an action or a set of actions result in desired changes. For example, motor learning theories suggest that motor learning results from experience and practice, which produces permanent changes in behavior. Motor learning theories also postulate that verbal feedback from the practitioner about the quality of movement helps the person know whether modification is needed for the next movement attempt (see Chapter 55 for a further review of motor learning theory).

EVALUATING KNOWLEDGE AND REFLECTIVE INQUIRY

It is essential to view theory as evolving knowledge. It is not a fixed, objective truth. Because theory involves the evolution of knowledge—whether it is formal theory or personal theory derived from professional experience and reflective inquiry—it needs constant examination and testing. This can involve continued research about the theory, critical examination of the research supporting the theory, or the reflective inquiry described by Schön (1983) and summarized earlier in Chapter 25 as it relates to competence and Chapter 32 as it relates to professional reasoning. Table 42.2 lists six questions that practitioners can use to guide the process of examining theoretical knowledge. These questions can be used to promote examination of published research and theories as well as to guide practitioner reflections on specific practice situations.

TABLE 42.2   EVALUATING THEORETICAL KNOWLEDGE FOR ACTION

What theory or theories are embedded in your practice?	◆ What theoretical knowledge do you use? ◆ Which theories are personal and which public?
What is the theory's focus?	◆ Who developed the theory? ◆ What is it trying to explain? ◆ What kind of clients or settings was it intended for? ◆ How well does it match your therapy needs?
How do you know?	◆ Upon what data is this knowledge based? ◆ What literature relates to this knowledge? ◆ How relevant is the literature to your needs?
How well do you know?	◆ How was the knowledge developed? ◆ How were the data collected? ◆ How were data analyzed and interpreted? ◆ What were the research circumstances? ◆ Where is the theory published? Is the venue of high quality? ◆ What were the qualifications of the authors of the theory?
How will your understanding shape your practice decisions?	◆ To what extent is this theory unique and offer a new way of considering your practice? ◆ How does the theory enhance your understanding? ◆ What are its strengths and limitations? ◆ How does this information affirm your current approaches? ◆ How does it contradict your current approaches? ◆ What different approaches will you use based on your understanding?
What additional information do you need?	◆ What further questions do you have? ◆ What sources can help answer these questions? ◆ How will you access this information?

Adapted from McColl et al., 2003; Watson, 2000

CONCLUSION

It is essential for a profession to have a base of knowledge grounded in well-articulated and specified theories that, in turn, provide scientific support for practice and test the effectiveness of occupational therapy interventions.

The following chapters in this unit provide an introduction to the occupation-based theories in our field. These are broad-based theories which form the knowledge base of the profession and provide important constructs of practitioners' professional paradigm. Units X through XII provide many examples of more focused theories, as well as how to blend the overarching perspectives of occupational theories with more focused theories and frames of reference guiding evaluation and intervention. One of the challenges of professional practice is the need to bridge the gap between current theoretical knowledge and practitioners' use of such knowledge within their professional paradigm. Taking a reflective stance toward practice assists practitioners to understand their professional reasoning and to explore the theoretical underpinnings of this process.

Ecological Models in Occupational Therapy

CATANA E. BROWN

43

Chapter Objectives

After reading this chapter, you will be able to:

1. Explain how an understanding of the environment is essential to understanding occupational performance.
2. Describe the ecological models (Ecology of Human Performance, Person Environment Occupation, and Person Environment Occupation Performance) and their concepts.
3. Describe and distinguish the five intervention strategies: establish/restore, adapt/modify, alter, prevent, and create.

In the 1990s, three groups of occupational therapists working independently created three separate models that emphasized the importance of considering the environment in occupational therapy practice. The three models, the Ecology of Human Performance model (EHP) (Dunn, Brown, & McGuigan, 1994), the Person Environment Occupational Performance model (PEOP) (Christiansen & Baum, 1997), and the Person Environment Occupation model (PEO) (Law et al., 1996) share many similarities and a few distinctions. The three dynamic models consider occupational (task) performance as the primary outcome of interest to occupational therapists. In addition, all of the models indicate that occupational performance is determined by the person, environment (context), and occupation (task). However, of the constructs of person, environment, and occupation, the developers of the models were most intent on promoting the significance of the environment. Occupational therapists tend to focus on person factors and neglect the influence of the environment on occupational performance. Therefore, the ecological models were developed so that along with consideration for the person and occupation, occupational therapy practice includes assessments and interventions that focus on the environment. When the distinct characteristics of the person, environment, and task are taken together, the uniqueness of each situation is fully appreciated. The differences

in the models lie primarily in the definitions, components, and structures of the models, which will be discussed further in the sections that follow.

INTELLECTUAL HERITAGE

The ecological models were built on social science theory, earlier occupational therapy models, and the disability movement. Each of the ecological models draws heavily on social science theories that describe person-environment interactions. Bronfenbrenner (1979) developed an ecological model that explored the influence of social factors on development. This nested model has the individual at the center of a system that is influenced by family, friends, communities, and institutions. These interactions can either enhance or inhibit development. For example, changes in economic systems have had a major influence on the family in terms of the increased numbers of women who are working. This in turn affects the development of the child. Gibson's (1979) concept of affordances is applied primarily to the physical environment. People perceive objects in the environment as having specific characteristics that result in action or meaning. People do not consciously think about affordances, but people's perceptions determine how they interact with objects. For example, the flat surface of a table affords such activities as eating a meal or writing a letter. Lawton (1986) developed the concept of environmental press. *Press* is described as the demands of the environment. A good fit occurs when the person's adaptive behavior and affect match the environmental press; a poor fit occurs when the person cannot meet the demands of the environment. When curb cuts are available, the environmental press is more adaptive for a wheelchair user; however, other environmental features, such as a sidewalk with a steep grade or snow, can create demands that make performance impossible. Csikszentmihalyi (1990) created another goodness-of-fit model based on the concept of flow. A flow experience occurs when the person's skills and abilities match the challenges of the activity. Even more, when in flow, the person is at one with the occupation and so completely absorbed that the passage of time goes unnoticed. The EHP, PEO, and PEOP models are also based on the idea of goodness of fit. Occupational performance is optimal when the environment and the person's skills and abilities match the demands of the occupation (task). A disruption in any area, person, environment, or occupation will interfere with performance.

Earlier models of occupational therapy do take account of the environment and contributed to the conceptualization of EHP, PEO, and PEOP. In the Model of Human Occupation (Kielhofner, 2004), environmental impact refers to the unique influence of the environment on the person. Environments are a source of opportunities and resources as well as demands and constraints. David Nelson (1988) makes a distinction between the terms *occupational performance* and *occupational form*. *Performance* is the doing of an occupation. *Form* is the context in which the doing takes place and includes the physical and sociocultural circumstances that are external to the person. Occupational form contributes to the personal meaning and purpose that the individual attributes to an occupation. Occupational Adaptation (Schkade & Schultz, 1992) proposes that the person desires mastery and the occupational environment demands mastery. Therefore, the interaction of the person and environment combine in a press for mastery that results in an adaptive response.

Finally, the ecological models in occupational therapy were influenced by civil rights movements that arose from disability groups. Health care practice is dominated by a focus on impairment in the person and interventions that are designed to fix that impairment. Individuals with disabilities have challenged this perspective. People in the independent living movement have pointed out that environmental barriers are typically the greatest impediment to a successful and satisfying life (DeJong, 1979; Shapiro, 1994). Furthermore, individuals with psychiatric disabilities have revealed that the power of stigma and the subsequent discrimination interfere with full participation in community life (Chamberlin, 1990; Deegan, 1993). The disability movements have pushed for civil rights for individuals with disabilities and promote self-determination and empowerment. The ecological models have embraced the values of the disability movement. This is reflected in both the emphasis on the environment as a significant barrier and facilitator of occupational performance and the adoption of principles of client-centered practice. In the ecological models, the first step in the occupational therapy process involves identifying the areas of occupational performance that are important to the individual. Moreover, the service recipient remains the primary decision maker in all steps of the process.

DEFINITIONS

Person

EHP, PEO, and PEOP have similar definitions of the person. A unique and holistic view of the person acknowledges the mind, body, and spirit. Variables associated with the person include values and interests, skills and abilities, and life experience. Values and interests help to determine what is important, meaningful, and enjoyable to the person. Skills and abilities include cognitive, social, emotional, and sensorimotor skills as well as abilities such as reading and knowing how to balance a checkbook. Life experiences form the person's history and personal narrative. The person influences and is influenced by the environment. For example, a person's family and friends contribute to the development of particular values and interests and vice versa. A child might develop a love of reading because of the availability of books in the home and parents who read to the child, while having a child in the home might cause the parents to be more concerned about having healthy foods at home and creating a safe physical environment.

Environment

The environment is also described similarly across the three models. The environment is where occupational performance takes place and consists of physical, cultural, and social components. The EHP model also includes the temporal environment. The physical environment is the most tangible. It includes built and natural features, large elements such as the terrain or buildings, and small objects such as tools. The cultural environment is based on shared experiences that determine values, beliefs, and customs. The cultural environment includes but is not limited by ethnicity, religion, and national identity. For example, individuals may also adopt values and beliefs from the culture of their family, professional identity, organizations or clubs, and peer group. The social environment is made up of many layers. It includes close interpersonal relationships such as family and friends. The next layer includes social groups such as work groups or social organizations to which the individual belongs. The social environment is also made up of large political and economic systems, which can have a profound effect on the daily life of people with disabilities. These systems make decisions related to the rights of people with disabilities, availability of services, and financial benefits such as social security disability insurance. The temporal environment is made up of time-oriented factors associated with the person (developmental and life stage) and the task (when it takes place, how often and how long). Occupational performance cannot be understood outside of the context or environment. The environment can both create barriers to performance and enhance occupational performance. For example, a well-organized and familiar grocery store that provides foods that are culturally familiar and consistent with the person's likes might be described as an adaptive environment. The grocery store might also be a barrier if the person is overwhelmed by many choices, cannot find the items he or she is looking for, and is anxious when there are too many people around.

Occupation/Task

The biggest difference in the three models is found in the concepts related to occupations or tasks. PEO and PEOP use the term *occupation,* whereas EHP uses *task.* The developers of EHP were intentional about the selection of the term *task* because a primary purpose of the model was to facilitate interdisciplinary collaboration. It was felt that the term *task* would be more accessible to other disciplines. Tasks are defined as objective representations of all possible activities available in the universe. Although this was not explicitly expressed in the early writings of EHP, occupations exist when the person and context factors come together to give meaning to tasks (Dunn, McClain, Brown, & Youngstrom, 2003). The PEO and PEOP models describe a series of nested concepts that make up occupations. In PEO, activities are the basic units of tasks. Tasks are purposeful activities, and occupations are self-directed tasks that a person engages in over the life course. The PEOP model involves actions, which are observable behaviors; tasks, which are combinations of actions with a common purpose; and occupations, which are goal-directed, meaningful pursuits that typically extend over time. For example, chopping vegetables might be the observable behavior or activity, embedded within the task of preparing soup, which falls under the larger occupation of cooking dinner for the family. See Table 43.1 for a comparison of definitions of the ecological models.

TABLE 43.1	DEFINITIONS OF TASK, ACTIVITY, AND OCCUPATION USED BY ECOLOGICAL MODELS			
	PEO	**PEOP**	**EHP**	**Example**
Activity	Recognizable and observable behavior	Basic units of tasks	Tasks and activities are not differentiated. Tasks are an objective set of behaviors necessary to achieve a goal.	Chopping vegetables
Task	Purposeful activities recognized by the task performer	Combinations of actions with a common purpose		Cooking a meal
Occupation	Self-directed tasks that a person engages in over the life course	Goal-directed meaningful pursuits that extend over time	Tasks that acquire meaning through the person-environment interaction	Making dinner for the family

Occupational Performance

Occupational performance is the outcome that is associated with the confluence of the person, environment, and occupation factors. The degree to which occupational performance is possible depends on the goodness of fit of these factors. The structures of the models are depicted in slightly different ways. In PEO, a Venn diagram is used to illustrate the meeting of person, environment, and occupation variables (Figure 43.1). The space in which the three circles come together is occupational performance. PEOP is similar however instead of three circles there are four (Figure 43.2). Person and environment touch but do not overlap. Occupation and performance are two separate circles that overlay person and environment. These circles come together to form occupational performance and participation. In EHP, the person is embedded inside the context, with tasks floating all around (Figure 43.3). The performance range includes the tasks that are available to the person because of the existing environment supports and his or her own skills, abilities and experiences. In all of the models, the performance range or occupational performance area is constantly changing as the other variables change. The area of occupational performance increases or the performance range expands when the person acquires new skills. Likewise, expansion occurs when stigma is decreased, physical barriers are removed, additional social supports are acquired, or schedules are accommodating. Unfortunately, many people with disabilities are often faced with limited personal capacities and multiple environmental barriers. The role of the occupational therapist is to change this dynamic so that more occupations are available to the person.

Intervention Strategies

Additional terms that are included in the EHP model are five different intervention strategies: (1) establish/restore, (2) adapt/modify, (3) alter, (4) prevent, and (5) create. These interventions were spelled out so that occupational therapists would consider the full range of options. In particular, the enumeration of intervention choices was designed to encourage occupational therapists to use more interventions directed at the environment.

◆ **Establish/restore interventions** target the person and are aimed at developing and improving skills and abilities so that the person can perform tasks (occupations) in context. Increasing range of motion so that an individual can better manage self-care tasks and teaching someone how to use a microwave oven for meal preparation involve establish/restore strategies.

◆ **Adapt/modify interventions** change the environment or task to increase the individual's performance range. Using assistive devices such as an adapted car for driving or a built-up handled spoon for eating are interventions that change the typical environment. Changes to the physical environments are most common in occupational therapy; however, it is important to consider interventions that target the social and cultural environment as well. Adapt/modify strategies can include providing education about disabilities to students in an elementary school classroom so that the special needs child will be more accepted. This is an adapt/modify

strategy because the social environment is being changed. Other adapt/modify interventions could include providing social support for someone who is fearful of riding the bus or changing the schedule for someone with endurance problems so that physically demanding tasks are spread throughout the day.

◆ **Alter interventions** do not change the person, task, or environment but are designed to make a better fit. Occupational therapists might be reluctant to consider alter interventions because it does not appear that they are "doing" anything. However, alter interventions can be some of the most effective because they take advantage of what is already naturally occurring. Making a good match requires that the occupational therapist have strong skills in activity analysis and environmental assessment. Moving from a two-story house with stairs to a ranch home would be an alter intervention for someone with limited endurance. Helping an individual to find a club or organization to join based on his or her values and beliefs would also utilize alter strategies. Matching the person's skills with a job match is another example of an alter intervention.

◆ **Prevent interventions** are implemented to change the course of events when a negative outcome is predicted. Prevention can utilize interventions that change the person (establish/restore), change the environment (adapt/modify), or make a better match (alter) but occur before the problem develops. Teaching at-risk parents skills in facilitating developmentally appropriate play is an example of a prevent strategy, as is using a special cushion in a wheelchair to prevent decubitus ulcers.

◆ **Create interventions** do not assume that a problem has occurred or will occur but are designed to promote performance in context. These interventions enrich occupational performance in context. Like the prevent strategies, create interventions can utilize establish/restore, adapt, or alter approaches. Setting up a study space within a quiet area with adequate lighting is a create strategy. Finding a good roommate match is another create strategy, and so is practicing interviewing skills before going out on an actual job interview.

ASSUMPTIONS OF THE ECOLOGICAL MODELS

◆ The relationships between people, environments, and occupations are dynamic and unique. They interact continually and across time and space. Therefore, occupational therapists should approach each situation as ever changing and distinct.

◆ The environment is a major factor in the prediction of successful and satisfying occupational performance. Environments can either facilitate or inhibit occupational performance. All aspects of the environment (physical, social, cultural, and temporal) should be evaluated to determine relevant environmental influences.

◆ Rather than exclusively using interventions that change the person, it is often more efficient and effective to change the environment or find a person-environment match.

◆ Occupational performance is determined by the confluence of person, environment, and occupation factors. People, environments, and occupations are constantly changing, and as these factors change, so does occupational performance.

◆ Occupation therapy practice begins by identifying what occupations the person wants or needs to perform. Using a top-down approach, the targeted area of occupational performance is identified first by the client or family. This is followed by an assessment of barriers and facilitators within the person, environment, and occupation that affect occupational performance.

◆ Occupational therapy practice involves promoting self-determination and the inclusion of people with disabilities in all environments. The person or system that is the service recipient is the primary decision maker in the occupational therapy process. Occupational therapists should act as advocates for people with disabilities and should support their clients in self-advocacy.

APPLICATION TO PRACTICE

The ecological models provide a framework for thinking about occupational therapy practice but do not delineate specific assessments or techniques. Using an ecological model requires an intentional effort on the part of the occupational therapist to consider the environment as extensively as he or she considers the person. An overarching value of the ecological models is a client-centered approach to practice. The person and occupational therapist collaborate throughout all stages of the occupational therapy process, and the process begins by identifying what the person wants or needs to do in his or her life (see Box 43.1). Consequently, the stage is set so that assessment and intervention are not driven by the therapist but are framed in terms of what is most important to the person. The person is not viewed in isolation but instead is considered in terms of the environment in which occupational performance takes place. The dynamic interrelationships of person, environment, and occupation compel the therapist to appreciate the uniqueness of each situation. This means that practice is not an unyielding protocol applied to everyone with the same diagnosis but a thoughtful, reasoned, and collaborative process of assessment and intervention.

Once the person identifies the relevant area(s) of occupational performance, the assessment process is directed at determining what features of the person, environment, and occupation support and interfere with occupational performance. Therefore, occupational therapy assessment must be comprehensive and include measures that consider the person, environment, and occupation. Occupational therapists are most familiar with measures of person factors and are skilled at complex task analysis. Environmental assessment is an area that has received less attention, though there are several good resources describing numerous environmental measures (Cooper, Letts, Rigby, Stewart, & Strong, 2001; Letts et al., 1994; Letts, Rigby, & Stewart, 2003). Occupational therapists should choose assessments that evaluate the environment in which the chosen occupation takes place. They should also conduct a skilled observation of the relevant environment. Observing the person performing the occupation in the natural environment is a powerful and informative assessment strategy. Therapists will need to bring in more specific practice models to guide the selection of assessments and later the inter-

CLINICAL QUESTIONS RELATED TO CONSTRUCTS OF THE ECOLOGICAL MODELS

Person

Skills (cognitive, social, psychological, sensory, motor)
- What are the person's inherent strengths?
- What are potential areas of cognitive, social, or sensorimotor impairment?

Life skills
- What life skills has the person learned and what skills has the person not learned?
- What life skills has the person mastered and what skills are problematic?

Interests
- What does the person like to do?

Experiences
- What are the life experiences that contribute to or interfere with occupational performance?
- What are the major life events for the person?
- What are themes in the person's life story?

Environment/Context

Culture
- What cultural groups does the person identify with?
- What values does the person derive from these cultural groups?
- Are the beliefs and expectations of these cultural groups accepting of the person?

Social
- Are friends and family available to provide support?
- What providers are involved?
- How does public policy influence the person's ability to engage in tasks or occupations?

Physical
- Does the built environment or the natural environment create barriers to performance?
- Does the person have access to objects that facilitate performance?

Temporal
- Is the person able to engage in occupations that are consistent with the person's developmental or life phases?
- Does the person have too much time or not enough time to perform important tasks or occupations?

Occupation/Tasks

- What does the person want or need to do?
- What occupations or tasks come together to create roles or identity for the person?
- What occupations or tasks give meaning to the person's life?

Performance/Performance Range

- Which tasks or occupations fall inside out outside of the performance range?
- Are there factors related to the person, environment/context, or occupation that interfere with performance?

Therapeutic Intervention

- What intervention approach would be the most efficient and have the most desirable outcomes?
- Is there evidence to support the intervention approach?
- Which intervention approach does the service recipient want?
